Davis's Comprehensive Handbook of Laboratory and Diagnostic Tests with Nursing Implications

Third Edition

Anne M. Van Leeuwen
Debra J. Poelhuis-Leth
Inspiration springs from Passion.... Passion is born from unconstrained love, commitment, and a vision no one else can own.

Lynda, thank you—I could not have done this without your love, strong support, and belief in me. My gratitude to Mom, Dad, Adele, Gram...all my family and friends, for I am truly blessed by your humor and faith. A huge hug for my daughters, Sarah and Margaret—I love you very much. To my puppies, Maggie, Taylor, and Emma for their endless and unconditional love. My thanks and welcome to Debra Poelhuis-Leth for her contributions to this third edition. And, very special thanks to Lisa Deitch, Publisher, for her friendship, excellent direction, and unwavering encouragement.

Anne M. Van Leeuwen, MA, BS, MT (ASCP)
Director of Laboratory Services
Highlands Regional Medical Center
Sebring, Florida

To my husband, Bill, who encouraged and supported me during this new adventure. To my beautiful children, Abbie and Andy, the lights of my life, please remember to always push yourselves to excel. Thanks Mom and Dad for always showing your pride in my endeavors. Anne, Lynette, Lisa, and Rob, your confidence in my abilities and your continued support, guidance, and assistance is greatly appreciated. I look forward to our continued relationship. And lastly, my thanks to Arlene Adler for recommending me for this awesome experience.

Debra J. Poelhuis-Leth, MS, RT, (R)(M)
Director, Radiology Program
Montgomery County Community College
Pottstown, Pennsylvania
The authors would like to thank all the users of the previous editions for helping us identify what they like about this book as well as what might improve its value. We want to continue this dialogue. As writers, it is our desire to capture the interest of our readers, to provide essential information, and to continue to improve the presentation of the material in the book and ancillary products. We encourage our readers to provide feedback to the Web site and to the company's sales professionals. Your feedback helps us modify the material—to change with your changing needs. Several new monographs have been added: urea breath test, anti-cyclic citrullinated peptide antibodies, and fluorodeoxyglucose PET scan. Monographs have been expanded to include additional information, for example: US OB biophysical profile, amniotic fluid analysis, and creatinine/eGFR. Some monographs have been combined to consolidate similar tests and a few less frequently used tests have been condensed into a mini-monograph format that highlights abbreviated test-specific facts, with the full monographs for those tests now resident on the DavisPlus Web site (http://davisplus.fadavis.com). The names of some test monographs have been changed to assist the reader in locating them more easily. For example, the tests that relate to the complete blood count have been renamed to begin with CBC, “test name” (CBC, hemoglobin; CBC, red blood cell count; etc.), so they are grouped together alphabetically in the text; the individual tests are also listed separately under their own names in the index. All of these changes have been made in response to feedback from our readers.

The authors have taken care to especially enhance four areas in this new edition: pathophysiology that affects test results, patient safety, patient education, and integration of related laboratory and diagnostic testing. First, the result section has been expanded to include an explanation of increased or decreased values, as many of you requested. Second, the authors appreciate that nurses are the strongest patient advocates with a huge responsibility to protect the safety of their patients, and we have observed student nurses in clinical settings being interviewed by facility accreditation inspectors, so we have integrated a number of reminders that parallel the Joint Commission’s national patient safety goals. The pretest section reminds the nurse to positively identify the patient before beginning a procedure, administering medications, etc. The pretest section also addresses hand-off communication of critical information. The third area of emphasis is that each monograph coach the student to focus on patient education and prepares the nurse to anticipate and respond to a patient’s questions or concerns; from describing the purpose of the procedure, addressing concerns about pain, understanding the implications of the test results, and describing postprocedural care. Various related Web sites for patient education have been included throughout the book. And fourth, laboratory and diagnostic tests do not stand on their own—all the pieces fit together to form a picture. The section at the end of each monograph that lists related tests by modality has been changed to integrate both laboratory and diagnostic tests. The authors thought it might be more useful for a nurse to know what other tests might be ordered together—and all the related tests are listed alphabetically for ease of use.
To make sure that we remain on target with each revision, we submit the manuscript to a thorough review process. Our reviewers look at the manuscript from both the nursing perspective and the technical perspective, and the insights they provide help mold every edition, but this edition’s review was particularly extensive and rigorous. To see the full list of reviewers who participated in the process, go to http://davisplus.fadavis.com.

Now—more about the details of this book—laboratory and diagnostic studies are essential components of a complete patient assessment. Examined in conjunction with an individual’s history and physical examination, laboratory and diagnostic data provide clues about health status. Nurses are increasingly expected to integrate an understanding of laboratory and diagnostic procedures and expected outcomes in assessment, planning, implementation, and evaluation of nursing care. The data help develop and support nursing diagnoses, interventions, and outcomes.

Nurses may interface with laboratory and diagnostic testing on several levels, including:

• Interacting with patients and families of patients undergoing diagnostic tests or procedures, and providing pretest, intratest, and post-test information and support
• Maintaining quality control to prevent or eliminate problems that may interfere with the accuracy and reliability of test results
• Ensuring completion of testing in a timely and accurate manner
• Collaborating with other health care professionals in interpreting findings as they relate to planning and implementing total patient care
• Communicating significant alterations in test outcomes to other appropriate health care team members
• Coordinating interdisciplinary efforts

Whether the nurse’s role at each level is direct or indirect, the underlying responsibility to the patient, family, and community remains the same.

This book is a reference for nurses, nursing students, and other health care professionals. It is useful as a clinical tool as well as a supportive text to supplement clinical courses. It guides the nurse in planning what needs to be assessed, monitored, treated, and taught regarding pretest requirements, intratest procedures, and post-test care. It can be used by nursing students at all levels as a textbook in theory classes, integrating laboratory and diagnostic data as one aspect of nursing care; by practicing nurses, to update information; and in clinical settings as a quick reference. Designed for use in academic and clinical settings, Davis’s Comprehensive Handbook of Laboratory and Diagnostic Tests—with Nursing Implications provides the user with a comprehensive reference that allows easy access to information about laboratory and diagnostic tests and procedures. A general overview of how all the tests and procedures included in this book relate to body systems can be found in tables at the end of the monographs. The tests and procedures are presented in this book in alphabetical order by their complete name, allowing the user to locate information quickly without having to first place tests in a specific category or body system. Each monograph is presented in a consistent format for easy identification of specific information at a glance. The following information is provided for each laboratory and diagnostic test:

• Test Name for each monograph is given as a commonly used designation, and all test monographs in the book are organized in alphabetical order by name.
• **Synonyms/Acronyms** for each test are listed where appropriate.

• **Specimen Type** includes the amount of specimen usually collected and, where appropriate, the type of collection tube or container commonly recommended. Specimen requirements vary from laboratory to laboratory. The amount of specimen collected is usually more than what is minimally required so that additional specimen is available, if needed, for repeat testing (quality control failure, dilutions, or confirmation of unexpected results). In the case of diagnostic tests, the type of procedure (e.g., nuclear medicine, x-ray) is given.

• **Reference Values** for each monograph include age-specific and gender-specific variations, when indicated. It is important to give consideration to the normal variation of laboratory values over the life span and across cultures; sometimes what might be considered an abnormal value in one circumstance is actually what is expected in another. Reference values for laboratory tests are given in conventional and standard international (SI) units. The factor used to convert conventional to SI units is also given. Because laboratory values can vary by method, each laboratory reference range is listed along with the associated methodology.

• **Description & Rationale** of the study’s purpose and insight into how and why the test results can affect health are included.

• **Indications** are a list of what the test is used for in terms of assessment, evaluation, monitoring, screening, identifying, or assisting in the diagnosis of a clinical condition.

• **Results** present a list of conditions in which values may be increased or decreased and, in some cases, an explanation of variations that may be encountered.

• **Critical Values**, or findings that may be life-threatening or for which particular concern may be indicated, are given along with age span considerations where applicable. This section also includes signs and symptoms associated with a critical value as well as possible nursing interventions.

• **Interfering Factors** are substances or circumstances that may influence the results of the test, rendering the results invalid or unreliable. Knowledge of interfering factors is an important aspect of quality assurance and includes pharmaceuticals, foods, natural and additive therapies, timing of test in relation to other tests or procedures, collection site, handling of specimen, and underlying patient conditions.

• **Nursing Implications and Procedure** provides an outline of pretest, intratest, and post-test concerns.

• **Pretest** section addresses the need to:
  • Obtain pertinent clinical, laboratory, dietary, and therapeutic history of the patient, especially as it pertains to comparison of previous test results, preparation for the test, and identification of potentially interfering factors.
  • Understand the interrelationship between various body systems. In this section, the reader is informed of the body systems that may be involved in the study of interest and is referred to body system tables where correlated laboratory and diagnostic studies are alphabetically listed.
  • Explain the requirements and restrictions related to the procedure as well as what to expect; provide the education necessary for the patient to be properly informed.
  • Anticipate and allay patient concerns or anxieties.
  • Provide for patient safety.
• Intratest section can be used in a quality control assessment by the nurse or as a guide to the nurse who may be called on to participate in specimen collection or perform preparatory procedures and gives:
  • Specific directions for specimen collection and test performance.
  • Important information such as patient sensation and expected duration of the procedure.
  • Precautions to be taken by the nurse and patient.
• Post-test section provides guidelines regarding:
  • Specific monitoring and therapeutic measures that should be performed after the procedure (e.g., maintaining bed rest, obtaining vital signs to compare with baseline values, signs and symptoms of complications).
  • Specific instructions for the patient and family, such as when to resume usual diet, medications, and activity.
  • General nutritional guidelines related to excess or deficit as well as common food sources for dietary replacement.
  • Indications for interventions from public health representatives or for special counseling related to test outcomes.
  • Indications for follow-up testing that may be required within specific time frames.
  • Related tests for consideration and evaluation, an alphabetical listing of related laboratory and/or diagnostic tests that is intended to provoke a deeper and broader investigation of multiple pieces of information; the tests provide related data that, when combined, can form a more complete picture of health or illness.
  • Reference to the specific body system tables of related laboratory and diagnostic tests that might bear on a patient's situation.

Color and icons have been used to facilitate locating critical information at a glance. On the inside front and back covers is a full color chart describing specific tube tops used for various blood tests and their recommended order of draw.

The nursing process is evident throughout the laboratory and diagnostic monographs. Within each phase of the testing procedure, the nurse has certain roles and responsibilities. These should be evident in reading each monograph.

Information provided in the appendices includes a summary of specimen collection procedures and materials; a summary chart of transfusion reactions, their signs and symptoms, associated laboratory findings, and potential nursing interventions; an introduction to CLIA (Clinical Laboratory Improvement Amendments) with an explanation of the different levels of testing complexity; a summary chart that details suggested approaches to persons at various developmental stages to assist the provider in facilitating cooperation and understanding; a list of some of the herbs and nutraceuticals that have been associated with adverse clinical reactions or have been associated with drug interactions related to the affected body system; and guidelines for Standard and Universal Precautions.

This book is also about teaching. Additional educationally supportive materials are provided for the instructor and student in an Instructor's Guide, available on the Instructor’s Resource Disk (CD) and posted to DavisPlus (http://davisplus.fadavis.com). Organized by nursing curriculum, presentations, and case studies with emphasis on laboratory and diagnostic test-related information and nursing implications have been developed for selected conditions and body systems; new to this edition is the sensory, obstetric, and
nutrition coverage. Open-ended and NCLEX-type multiple-choice questions are provided as well as suggested critical thinking activities. This supplemental material will aid the instructor in integrating laboratory and diagnostic materials in assessment and clinical courses and provide examples of activities to enhance student learning.

Newly developed for this third edition is a robust collection of online material for students and educators posted to the DavisPlus Web site (http://davisplus.fadavis.com) including:

- a searchable library of mini-monographs for all the active tests included in the text itself. The mini-monograph gives each test’s full name, synonyms/acronyms, specimen type (laboratory tests) or area of application (diagnostic tests), reference ranges or contrast, and results
- an archive of full monographs of retired tests that are referenced by mini-monographs in the text
- interactive drag and drop, quiz show, flash card, and multiple-choice exercises
- a printable file of critical values
- a printable table of monograph template section titles matched to corresponding national patient safety goals
- all the instructor and student material from the Instructor’s Resource Disk.

The authors hope that the changes and additions they’ve made to the book and its CD- and Web-based ancillaries will reward users with an expanded understanding of and appreciation for the place laboratory and diagnostic testing holds in the provision of high-quality nursing care as well as made it easy for instructors to integrate this important content in their curricula.
Laboratory and diagnostic testing. The words themselves often conjure up cold and impersonal images of needles, specimens lined up in collection containers, and high-tech electronic equipment. But they do not stand alone. They are tied to, bound with, and tell of health or disease in the blood and tissue of a person. Laboratory and diagnostic studies augment the health care provider’s assessment of the quality of an individual’s physical being. Test results guide the plans and interventions geared toward strengthening life’s quality and endurance. Beyond the pounding noise of the MRI, the cold steel of the x-ray table, the sting of the needle, the invasive collection of fluids and tissue, and the probing and inspection is the gathering of evidence that supports the health care provider’s ability to discern the course of a disease and the progression of its treatment. Laboratory and diagnostic data must be viewed with thought and compassion, however, as well as with microscopes and machines. We must remember that behind the specimen and test result is the person from whom it came, a person who is someone’s son, daughter, mother, father, husband, wife, friend.

This book is written to help health care providers in their understanding and interpretation of laboratory and diagnostic procedures and their outcomes. Just as important, it is dedicated to all health care professionals who experience the wonders in the science of laboratory and diagnostic testing, performed and interpreted in a caring and efficient manner.

**Acetylcholine Receptor Antibody**

**SYNONYM/ACRONYM:** AChR.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Radioimmunoassay) Less than 0.03 nmol/L.

**DESCRIPTION:** Normally when impulses travel down a nerve, the nerve ending releases a neurotransmitter called acetylcholine (ACh), which binds to receptor sites in the neuromuscular junction, eventually resulting in muscle contraction. Once the neuromuscular junction has been polarized ACh is rapidly metabolized by the enzyme acetylcholinesterase. When present, acetylcholine receptor (AChR) antibodies block ACh from binding to receptor sites on the muscle membrane. AChR antibodies also destroy AChR sites, interfering with neuromuscular transmission and causing muscle weakness. Antibodies to AChR sites are present in 90% of patients with generalized myasthenia gravis (MG) and in 55% to 70% of patients who either have ocular forms of MG or are in remission. MG is an acquired autoimmune disorder that can occur at any age. It seems to strike women between the ages of 20 and 40 years; men appear to be affected later in life than women. It can affect any voluntary muscle, but muscles that control eye, eyelid, and facial movement and swallowing are most frequently affected. Antibodies may not be detected in the first six to twelve months after the first appearance of symptoms. MG is a common complication associated with thymoma. The relationship between the thymus gland and MG is not completely understood. It is believed that miscommunication in the thymus gland directed at developing immune cells may trigger the development of autoantibodies responsible for MG. Remission after thymectomy is associated with a progressive decrease in antibody level. Other markers used in the study of MG include muscle AChR-binding antibodies, muscle AChR-blocking antibodies, muscle AChR-modulating antibodies, striational antibodies, thyroglobulin, HLA-B8, and HLA-DR3. These antibodies are often undetectable in the early stages of MG.

**INDICATIONS:**
- Confirm the presence, but not the severity, of MG
- Detect subclinical MG in the presence of thymoma
- Monitor the effectiveness of immunosuppressive therapy for MG
- Monitor the remission stage of MG

**RESULT:**

**Increased in:**
- (It is believed that miscommunication in the thymus gland directed at developing immune cells may trigger the development of autoantibodies responsible for MG.)
- Generalized MG
- Thymoma associated with MG

**Decreased in:**
- Post-thymectomy (The thymus gland produces the T-lymphocytes responsible for cell-mediated immunity. T-cells also help control B-cell development for the production of antibodies. T-cell response is directed at
cells in the body that have been infected by bacteria, viruses, parasites, fungi, or protozoans. T-cells also provide immune surveillance for cancerous cells. Removal of the thymus gland is strongly associated with a decrease in AChR antibody levels.)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs that may increase AChR levels include penicillamine (long-term use may cause a reversible syndrome that produces clinical, serological, and electrophysiological findings indistinguishable from MG).
- Biological false-positive results may be associated with amyotrophic lateral sclerosis, autoimmune hepatitis, Eaton-Lambert myasthenic syndrome, primary biliary cirrhosis, and encephalomyeloneuropathies associated with carcinoma of the lung.
- Immunosuppressive therapy is the recommended treatment for MG; prior immunosuppressive drug administration may result in negative test results.
- Recent radioactive scans or radiation within 1 wk of the test can interfere with test results when radioimmunoassay is the test method.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status may interfere with the test results.

DECREASED NEUROMUSCULAR TRANSMISSION AND ASSOCIATED MUSCLE WEAKNESS.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, and any prior complications with general anesthesia.
- Obtain a history of the patient’s musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting health care provider
(HCP), who will discuss the results with the patient.

- Recognize anxiety related to test results, and be supportive of impaired activity related to lack of neuromuscular control, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of positive test results on the patient’s lifestyle. It is important to note that a diagnosis of MG should be based on positive results from two different diagnostic tests. These tests include AChR antibody assay, edrophonium test, repetitive nerve stimulation, and single-fiber electromyography. Thyrotoxicosis may occur in conjunction with MG; related thyroid testing may be indicated. MG patients may also produce antibodies that demonstrate reactivity in tests like ANA and RF that are not primarily associated with MG. Evaluate test results in relationship to a future general anesthesia, especially regarding therapeutic management of MG with cholinesterase inhibitors. Succinylcholine-sensitive patients may be unable to metabolize the anesthetic quickly, resulting in prolonged or unrecoverable apnea. Provide teaching and information regarding the clinical implications of the test results as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the Myasthenia Gravis Foundation of America (www.myasthenia.org) and Muscular Dystrophy Association (www.mdausa.org).

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. If a diagnosis of MG is made, a computed tomography (CT) scan of the chest should be performed to rule out thymoma. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ANA, antithyroglobulin and antithyroid peroxidase antibodies, CT chest, myoglobin, pseudocholinesterase, RF, TSH, and total T4.
- Refer to the Musculoskeletal System table at the back of the book for related tests by body system.

---

**Acid Phosphatase, Prostatic**

**SYNONYM/ACRONYM:** Prostatic acid phosphatase, o-phosphoric monoester phosphohydrolase, AcP.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

A swab with vaginal secretions may be submitted in the appropriate transfer container. Other material such as clothing may be submitted for analysis. Consult the laboratory or emergency services department for the proper specimen collection instructions and containers.

**REFERENCE VALUE:** (Method: Spectrophotometric)

RESULT:

**Increased in:**
- AcP is released from any damaged cell in which it is stored so diseases of the bone, prostate, and liver that result in cellular destruction demonstrate elevated AcP levels. Conditions that result in abnormal elevations of cells that contain AcP (e.g., leukemia, thrombocytosis) or conditions that result in rapid cellular destruction (sickle cell crisis) also reflect increased levels.
- Acute myelogenous leukemia
- After prostate surgery or biopsy
- Benign prostatic hypertrophy
- Liver disease
- Lysosomal storage diseases (Gaucher’s disease and Niemann-Pick disease). (*AcP is stored in the lysosomes of blood cells and increased levels are present in lysosomal storage diseases.*)
- Metastatic bone cancer
- Paget’s disease
- Prostatic cancer
- Prostatic infarct
- Prostatitis
- Sickle cell crisis
- Thrombocytosis

**Decreased in:** N/A

**CRITICAL VALUES:** N/A

---

**Adrenal Gland Scan**

**SYNONYM/ACRONYM:** Adrenal scintiscan.

**AREA OF APPLICATION:** Adrenal gland.

**CONTRAST:** Intravenous radioactive NP-59 (iodomethyl-19-norcholesterol) or metaiodobenzylguanidine (MIBG).

**DESCRIPTION:** This nuclear medicine study evaluates function of the adrenal glands. The secretory function of the adrenal glands is controlled primarily by the anterior pituitary, which produces adrenocorticotropic hormone (ACTH). ACTH stimulates the adrenal cortex to produce cortisol and secrete aldosterone. Adrenal imaging is most useful in differentiating hyperplasia versus adenoma in primary aldosteronism when computed tomography (CT) and magnetic resonance imaging (MRI) findings are equivocal. High concentrations of cholesterol (the precursor in the synthesis of adrenocorticosteroids, including aldosterone) are stored in the adrenal cortex. This allows the radionuclide, which attaches to the cholesterol, to be used in identifying pathology in the secretory function of the adrenal cortex. The uptake of the radionuclide occurs gradually over time; imaging is performed within 24 to 48 hr of injection of the radionuclide dose and continued daily for 3 to 5 days. Imaging reveals increased uptake, unilateral or bilateral uptake, or absence of uptake in the detection of pathological processes. Following prescanning treatment with corticosteroids, suppression studies can be done to differentiate the presence of tumor from hyperplasia of the glands.
INDICATIONS:
• Aid in the diagnosis of Cushing’s syndrome and aldosteronism
• Aid in the diagnosis of gland tissue destruction caused by infection, infarction, neoplasm, or suppression
• Aid in locating adrenergic tumors
• Determine adrenal suppressibility with prescan administration of corticosteroid to diagnose and localize adrenal adenoma, aldosteronomas, androgen excess, and low-renin hypertension
• Differentiate between asymmetric hyperplasia and asymmetry from aldosteronism with dexamethasone suppression test

RESULT:
Normal findings in:
• No evidence of tumors, infection, infarction, or suppression
• Normal bilateral uptake of radionuclide and secretory function of adrenal cortex
• Normal salivary glands and urinary bladder; vague shape of the liver and spleen sometimes seen

Abnormal findings in:
• Adrenal gland suppression
• Adrenal infarction
• Adrenal tumor
• Hyperplasia
• Infection
• Pheochromocytoma

CRITICAL VALUES: N/A

INTERFERING FACTORS:
This procedure is contraindicated for:
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.

Factors that may impair clear imaging:
• Retained barium from a previous radiological procedure

• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
• Improper injection of the radionuclide may allow the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their radiation exposure level.

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure helps assess adrenal gland function.
• Obtain a history of the patient’s complaints, including a list of known allergens.
• Obtain a history of results of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• All adrenal blood tests should be done before doing this test.
• Record the date of last menstrual period and determine the possibility of pregnancy in perimenopausal women.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a nuclear medicine department by a
nuclear medicine technologist with support staff, and takes approximately 60 to 120 min each day. Inform the patient the test usually involves a prolonged scanning schedule over a period of days. Administer saturated solution of potassium iodide (SSKI) 24 hr before the study to prevent thyroid uptake of the free radioactive iodine.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. Explain that an IV line may be inserted to allow infusion of radionuclides or IV fluids. There are no food, fluid, or medication restrictions unless by medical direction. Instruct the patient to remove jewelry and other metallic objects from the area to be examined. Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure that the patient has removed external metallic objects from the area to be examined prior to the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Insert an IV line, and inject the radionuclide IV on day 1; images are taken on days 1, 2, and 3. Imaging is done from the urinary bladder to the base of the skull to scan for a primary tumor. Each image takes 20 min, and total imaging time is 1 to 2 hr per day.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 24 to 48 hr.
- No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- Observe the needle site for bleeding, hematoma formation, and inflammation.
- Instruct the patient in the care and assessment of the injection site.
- Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. Instruct her to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 48 hr after the procedure.
- Instruct all caregivers to wear gloves when discarding urine for 48 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash ungloved hands after the gloves are removed.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Advise the patient that SSKI (120 mg/d) will be administered for 10 days after the injection of the radionuclide. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.
**Adrenocorticotropic Hormone (and Challenge Tests)**

**SYNONYM/ACRONYM:** Corticotropin, ACTH.

**SPECIMEN:** Plasma (2 mL) from lavender-top (EDTA) tube for adrenocorticotropic hormone (ACTH), and serum (1 mL) from a red-top tube for cortisol. Collect specimens in a prechilled heparinized plastic syringe, and carefully transfer into collection containers by gentle injection to avoid hemolysis. Alternatively, specimens can be collected in prechilled lavender- and red-top tubes. Tiger- and green-top (heparin) tubes are also acceptable for cortisol, but take care to use the same type of collection container for serial measurements. Immediately transport specimen tightly capped and in an ice slurry to the laboratory. The specimens should be immediately processed. Plasma for ACTH analysis should be transferred to a plastic container.

### Procedure | Medication Administered, Adult Dosage | Recommended Collection Times
--- | --- | ---
ACTH stimulation, rapid test | 1 mg (low-dose protocol) cosyntropin IM | 3 cortisol levels: baseline immediately before bolus, 30 min after bolus, and 60 min after bolus
Corticotropin-releasing hormone (CRH) stimulation | IV dose of 1 mg/kg ovine CRH at 9 a.m. or 8 p.m. | 8 cortisol and 8 ACTH levels: baseline collected 15 min before injection, 0 min before injection, and then 5, 15, 30, 60, 120, and 180 min after injection
Dexamethasone suppression (overnight) | Oral dose of 1 mg dexamethasone (Decadron) at 11 p.m. | Collect cortisol at 8 a.m. on the morning after the dexamethasone dose
Metyrapone stimulation (overnight) | Oral dose of 30 mg/kg metyrapone with snack at midnight | Collect cortisol and ACTH at 8 a.m. on the morning after the metyrapone dose

IM = intramuscular, IV = intravenous.

REFERENCE VALUE: (Method: Immunoradiometric assay)
INDICATIONS:
• Determine adequacy of replacement therapy in congenital adrenal hyperplasia
• Determine adrenocortical dysfunction
• Differentiate between increased ACTH release with decreased cortisol levels and decreased ACTH release with increased cortisol levels

RESULT:
ACTH Result:
Because ACTH and cortisol secretion exhibit diurnal variation with values being biggest in the morning, a lack of change in values from morning to evening is clinically significant. Decreased concentrations of hormones secreted by the pituitary gland and its target organs are observed in hypo-pituitarism. In primary adrenal insufficiency (Addison’s disease) due to adrenal gland destruction by tumor, infectious process, or immune reaction, ACTH levels are elevated while cortisol levels are decreased. Both ACTH and cortisol levels are decreased in secondary adrenal insufficiency (i.e., secondary to pituitary insufficiency). Excess ACTH can be produced ectopically by various lung cancers such as oat cell carcinoma and large-cell carcinoma of the lung and by benign bronchial carcinoid tumor.

Challenge Tests and Results:
The ACTH (cosyntropin) stimulated rapid test directly evaluates adrenal gland function and indirectly evaluates pituitary gland and hypothalamus function. Cosyntropin is a synthetic form of ACTH. A baseline cortisol level is collected before the injection of cosyntropin. Specimens are subsequently collected at 30- and 60-min intervals. If the adrenal glands function normally, cortisol levels rise significantly after administration of cosyntropin.

The CRH stimulation test works as well as the dexamethasone suppression test (DST) in distinguishing Cushing’s disease from conditions in which ACTH is secreted ectopically (e.g., tumors not located in the pituitary gland that secrete ACTH). Patients with pituitary tumors tend to respond to CRH stimulation, whereas those with ectopic tumors do not. Patients with adrenal insufficiency demonstrate one of three

DESCRIPTION: Hypothalamic-releasing factor stimulates the release of adrenocorticotropic hormone (ACTH) from the anterior pituitary gland. ACTH stimulates adrenal cortex secretion of glucocorticoids, androgens, and, to a lesser degree, mineralocorticoids. Cortisol is the major glucocorticoid secreted by the adrenal cortex. ACTH and cortisol test results are evaluated together because normally a change in one causes a change in the other. ACTH secretion is stimulated by insulin, metyrapone, and vasopressin. It is decreased by dexamethasone. Cortisol excess from any source is termed Cushing syndrome. Cortisol excess resulting from ACTH excess produced by the pituitary is termed Cushing disease. ACTH levels exhibit a diurnal variation, peaking between 6 and 8 a.m. and reaching the lowest point between 6 and 11 p.m. Evening levels are generally one-half to two-thirds lower than morning levels. Cortisol levels also vary diurnally, with the lowest values occurring during the morning and peak levels occurring in the evening.

Access additional resources at davisplus.fadavis.com
patterns depending on the underlying cause:

- **Primary adrenal insufficiency**—high baseline ACTH (in response to intravenous [IV] ACTH) and low cortisol levels pre- and post-IV ACTH.
- **Secondary adrenal insufficiency** (pituitary)—low baseline ACTH that does not respond to ACTH stimulation. Cortisol levels do not increase after stimulation.
- **Tertiary adrenal insufficiency** (hypothalamic)—low baseline ACTH with an exaggerated and prolonged response to stimulation. Cortisol levels usually do not reach 20 mcg/dL.

The DST is useful in differentiating the causes of increased cortisol levels. Dexamethasone is a synthetic glucocorticoid that is 64 times more potent than cortisol. It works by negative feedback. It suppresses the release of ACTH in patients with a normal hypothalamus. A cortisol level less than 3.0 mcg/dL usually excludes Cushing’s syndrome. With the DST, a baseline morning cortisol level is collected, and the patient is given a 1-mg dose of dexamethasone at bedtime. A second specimen is collected the following morning. If cortisol levels have not been suppressed, adrenal adenoma is suspected. The DST also produces abnormal results in the presence of certain psychiatric illnesses (e.g., endogenous depression).

The metyrapone stimulation test is used to distinguish corticotropin-dependent causes (pituitary Cushing’s disease and ectopic Cushing’s disease) from corticotropin-independent causes (e.g., carcinoma of the lung or thyroid) of increased cortisol levels. Metyrapone inhibits the conversion of 11-deoxycorticisol to cortisol. Cortisol levels should decrease to less than 3 mcg/dL if normal pituitary stimulation by ACTH occurs after an oral dose of metyrapone. Specimen collection and administration of the medication are performed as with the overnight dexamethasone test.

**Increased in:**

- Overproduction of ACTH can occur as either a direct result of disease (e.g., primary or ectopic tumor that secretes ACTH), stimulation by physical or emotional stress, or an indirect response to abnormalities in the complex feedback mechanisms involving the pituitary gland, hypothalamus, or adrenal glands.

**ACTH Increased in:**

- Addison’s disease (primary adrenocortical hypofunction)
- Carcinoid syndrome
- Congenital adrenal hyperplasia
- Cushing’s disease (pituitary-dependent adrenal hyperplasia)
- Depression
- Ectopic ACTH-producing tumors
- Menstruation
- Nelson’s syndrome (ACTH-producing pituitary tumors)
- Non-insulin-dependent diabetes
- Pregnancy
- Sepsis
- Septic shock

**Decreased in:**

- Secondary adrenal insufficiency due to hypopituitarism (inadequate production by the pituitary) can result in decreased levels of ACTH.

**ACTH Decreased in:**

- Adrenal adenoma
- Adrenal cancer
- Cushing syndrome
- Conditions that result in overproduction or availability
of high levels of cortisol can result in decreased levels of ACTH.

- Exogenous steroid therapy

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase ACTH levels include estrogens, insulin, metoclopramide, metyrapone, mifepristone (RU 486), and vasopressin.
- Drugs that may decrease ACTH levels include corticosteroids (e.g., dexamethasone) and pravastatin.
- Test results are affected by the time the test is done because ACTH levels vary diurnally, with the highest values occurring between 6 and 8 a.m. and the lowest values occurring at night. Samples should be collected at the same time of day, between 6 and 8 a.m.
- Excessive physical activity can produce elevated levels.
- Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when immunoradiometric assay is the test method.
- The metyrapone stimulation test is contraindicated in patients with suspected adrenal insufficiency.
- Metyrapone may cause gastrointestinal distress and/or confusion. Administer oral dose of metyrapone with milk and snack.
- Rapid clearance of metyrapone, resulting in falsely increased cortisol levels, may occur if the patient is taking drugs that enhance steroid metabolism (e.g., phenytoin, rifampin, phenobarbital, mitotane, and corticosteroids). The primary care practitioner should be consulted prior to a metyrapone stimulation test regarding a decision to withhold these medications.

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess for pituitary hormone deficiency.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Weigh patient and report weight to pharmacy for dosing of metyrapone (30 mg/kg body weight).
- Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, especially drugs that enhance steroid metabolism, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. When ACTH hypersecretion is suspected, a second sample may be requested between 6 and 8 p.m. to determine if changes are the result of diurnal variation in ACTH levels. Inform the patient that more than one sample may be necessary to ensure accurate results and samples are obtained at specific times to determine high and low levels of ACTH. Inform the patient that each specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.
- Drugs that enhance steroid metabolism may be withheld by medical direction prior to metyrapone stimulation testing.
Instruct the patient to refrain from strenuous exercise for 12 hr before the test and to remain in bed or at rest for 1 hr immediately before the test. Avoid smoking and alcohol use.

Prepare an ice slurry in a cup or plastic bag to have on hand for immediate transport of the specimen to the laboratory.

**INTRATEST:**

- Ensure that strenuous exercise was avoided for 12 hr before the test and that 1 hr of bed rest was taken immediately before the test. Samples should be collected between 6 and 8 a.m.
- Have emergency equipment readily available in case of adverse reaction to metyrapone.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a prechilled plastic heparinized syringe or in prechilled collection containers as listed under the “Specimen” subheading.
- Adverse reactions to metyrapone include nausea and vomiting (N/V), abdominal pain, headache, dizziness, sedation, allergic rash, decreased WBC count, and bone marrow depression. Signs and symptoms of overdose or acute adrenocortical insufficiency include cardiac arrhythmias, hypotension, dehydration, anxiety, confusion, weakness, impairment of consciousness, N/V, epigastric pain, diarrhea, hyponatremia, and hyperkalemia.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag.

**POST-TEST:**

- A written report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume normal activity as directed by the HCP.
- Recognize anxiety related to test results, and offer support. Provide contact information, if desired, for the Cushing's Support and Research Foundation (www.csrf.net).
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. If a diagnosis of Cushing’s disease is made, pituitary computed tomography (CT) or magnetic resonance imaging (MRI) may be indicated prior to surgery. If a diagnosis of ectopic corticotropin syndrome is made, abdominal CT or MRI may be indicated prior to surgery. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include cortisol and challenge tests, CT abdomen, CT pituitary, MRI abdomen, MRI pituitary, TSH, and thyroxine.
- See the Endocrine System table at the back of the book for related tests by body system.
**Synonym/Acronym:** Serum glutamic pyruvic transaminase (SGPT), ALT.

**Specimen:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

**Reference Value:** (Method: Spectrophotometry)

**Result:**

**Increased in:**
- ALT is released from any damaged cell in which it is stored. These conditions affect the liver, kidneys, heart, or skeletal muscle and cause cellular destruction, demonstrating elevated ALT levels.
  - Acquired immune deficiency syndrome (related to Hepatitis B coinfection)
  - Acute pancreatitis
  - Biliary tract obstruction
  - Burns (severe)
  - Chronic alcohol abuse
  - Cirrhosis
  - Fatty liver
  - Hepatic carcinoma
  - Hepatitis
  - Infectious mononucleosis
  - Muscle injury from intramuscular injections, trauma, infection, and seizures (recent)
  - Muscular dystrophy
  - Myocardial infarction
  - Myositis
  - Pre-eclampsia
  - Shock (severe)

**Decreased in:**
- Pyridoxal phosphate deficiency (Pyridoxal phosphate is a required coenzyme in the amino transfer reactions)

**Critical Values:** N/A

**Description:** Alanine aminotransferase (ALT), formerly known as serum glutamic pyruvic transaminase (SGPT), is an enzyme produced by the liver. The highest concentration of ALT is found in liver cells, moderate amounts are found in kidney cells, and smaller amounts are found in heart, pancreas, spleen, skeletal muscle, and red blood cells. When liver damage occurs, serum levels of ALT rise to 50 times normal, making this a useful test in evaluating liver injury.

**Indications:**
- Compare serially with aspartate aminotransferase (AST) levels to track the course of liver disease
- Monitor liver damage resulting from hepatotoxic drugs
- Monitor response to treatment of liver disease, with tissue repair indicated by gradually declining levels

Access additional resources at davisplus.fadavis.com
INTERFERING FACTORS:

- Drugs that may increase ALT levels by causing cholestasis include anabolic steroids, dapsone, estrogens, ethionamide, icterogenin, mepazine, methandriol, oral contraceptives, oxymetholone, propoxyphene, sulfonyleureas, and zidovudine.

- Drugs that may increase ALT levels by causing hepatocellular damage include acetaminophen (toxic), acetylsalicylic acid, amiodarone, anticonvulsants, asparaginase, carbutamide, cephalosporins, chloramphenicol, clofibrate, cytarabine, danazol, dinitrophenol, enflurane, erythromycin, ethambutol, ethionamide, ethothio, florantyrone, foscarinet, gentamicin, gold salts, halothane, ibufenac, indomethacin, interleukin-2, isoniazid, lincomycin, low-molecular-weight heparin, metatexalonn, methoxsalen, methyldopa, methyliouracil, naproxen, nitrofurans, oral contraceptives, probenecid, procainamide, and tetracyclines.

- Drugs that may decrease ALT levels include cyclosporine, interferon, and ursodiol.

Obtain a list of the patient's current medications including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

- If the patient has a history of an allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle, and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding and hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

Nutritional considerations: Increased ALT levels may be associated with liver disease. Dietary recommendations should be discussed with the patient and the healthcare provider.
may be indicated and vary depending on the severity of the condition. A low-protein diet may be in order if the patient’s liver has lost the ability to process the end products of protein metabolism. A diet of soft foods may be required if esophageal varices have developed. Ammonia levels may be used to determine whether protein should be added to or reduced from the diet. Patients should be encouraged to eat simple carbohydrates and emulsified fats (as in homogenized milk or eggs), as opposed to complex carbohydrates (e.g., starch, fiber, and glycogen [animal carbohydrates]) and complex fats, which would require additional bile to emulsify them so that they can be used. The cirrhotic patient should be carefully observed for the development of ascites, in which case fluid and electrolyte balance requires strict attention.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include acetaminophen, ammonia, AST, bilirubin, biopsy liver, cholangiography percutaneous transhepatic, electrolytes, GGT, hepatitis antigens and antibodies, LDH, liver and spleen scan, and US liver.
- See the Hepatobiliary System table at the back of the book for related tests by body system.

### Albumin and Albumin/Globulin Ratio

**SYNONYM/ACRONYM:** Alb, A/G ratio.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

**REFERENCE VALUE:** (Method: Spectrophotometry) Normally the albumin/globulin (A/G) ratio is greater than 1.

</table>
DESCRIPTION: Most of the body’s total protein is a combination of albumin and globulins. Albumin, the protein present in the highest concentrations, is the main transport protein in the body. Albumin is synthesized in the liver. Low levels of albumin may be the result of either inadequate intake, inadequate production, or excessive loss. Albumin levels are more useful as an indicator of chronic deficiency than of short-term deficiency.

Albumin levels are affected by posture. Results from specimens collected in an upright posture are higher than results from specimens collected in a supine position.

The albumin/globulin (A/G) ratio is useful in the evaluation of liver and kidney disease. The ratio is calculated using the following formula:

\[
\text{albumin}/(\text{total protein} – \text{albumin})
\]

where globulin is the difference between the total protein value and the albumin value. For example, with a total protein of 7 g/dL and albumin of 4 g/dL, the A/G ratio is calculated as
\[
4/(7 - 4) = 4/3 = 1.33
\]

A reversal in the ratio, where globulin exceeds albumin (i.e., ratio less than 1.0), is clinically significant.

INDICATIONS:
- Assess nutritional status of hospitalized patients, especially geriatric patients
- Evaluate chronic illness
- Evaluate liver disease

RESULT:

Increased in:
- Any condition that results in a decrease of plasma water

Decreased in:
- Insufficient intake:
  - Malabsorption
  - Malnutrition
- Decreased synthesis by the liver:
  - Acute and chronic liver disease (e.g., alcoholism, cirrhosis, hepatitis)
  - Genetic analbuminemia
- Inflammation and chronic diseases result in production of acute phase reactant and other globulin proteins; the increase in globulins causes a corresponding decrease in albumin:
  - Amyloidosis
  - Bacterial infections
  - Monoclonal gammopathies (e.g., multiple myeloma, Waldenström’s macroglobulinemia)
  - Neoplasm
  - Parasitic infestations
  - Peptic ulcer
  - Prolonged immobilization
  - Rheumatic diseases
  - Severe skin disease
- Increased loss over body surface:
  - Burns
  - Enteropathies related to sensitivity to ingested substances (e.g., gluten sensitivity, Crohn’s disease, ulcerative colitis)
  - Fistula (gastrointestinal or lymphatic)
  - Hemorrhage
  - Kidney disease
  - Rapid hydration or overhydration
  - Repeated thoracentesis or paracentesis
  - Trauma and crush injuries
Obtain a list of the patient’s current medications including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

*Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.*

There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

These values reflect a normal-sodium diet. Values for a low-sodium diet are three to five times higher.

DESCRIPTION: Aldosterone is a mineralocorticoid secreted by the zona glomerulosa of the adrenal cortex in response to decreased serum sodium, decreased blood volume, and increased serum potassium. Aldosterone increases sodium.

Find and print out the full monograph at DavisPlus (davisplus.fadavis.com, keyword Van Leeuwen).
reabsorption in the renal tubules, resulting in potassium excretion and increased water retention, blood volume, and blood pressure. A variety of factors influence serum aldosterone levels, including sodium intake, certain medications, and activity. This test is of little diagnostic value unless plasma renin activity is measured simultaneously (see monograph titled “Renin”). Patients with serum potassium less than 3.6 mEq/L and 24-hour urine potassium greater than 40 mEq/L fit the general criteria to test for aldosteronism. Renin is low in primary aldosteronism and high in secondary aldosteronism. A ratio of plasma aldosterone to plasma renin activity greater than 50 is significant. Ratios greater than 20 obtained after unchallenged screening may indicate the need for further evaluation with a sodium-loading protocol. A captopril protocol can be substituted for patients who may not tolerate the sodium-loading protocol.

**INDICATIONS:**
- Evaluate hypertension of unknown cause, especially with hypokalemia not induced by diuretics
- Investigate suspected hyperaldosteronism, as indicated by elevated levels
- Investigate suspected hypoaldosteronism, as indicated by decreased levels

**RESULT:**

**Increased with Decreased Renin Levels**

**Primary hyperaldosteronism (overproduction due to abnormal adrenal gland function):**
- Adenomas (Conn’s syndrome)

**Increased with Increased Renin Levels**

**Secondary hyperaldosteronism (some conditions that result in increased renin levels will stimulate aldosterone secretion):**
- Bartter’s syndrome
- Cardiac failure
- Chronic obstructive pulmonary disease
- Cirrhosis with ascites formation
- Diuretic abuse (directly stimulates aldosterone secretion)
- Hypovolemia secondary to hemorrhage and transudation
- Laxative abuse (directly stimulates aldosterone secretion)
- Nephrotic syndrome
- Starvation (after 10 days)
- Thermal stress
- Toxemia of pregnancy

**Decreased in:**

**Without hypertension:**
- Addison’s disease (the adrenal cortex is not functioning, therefore aldosterone is not secreted)
- Hypoaldosteronism secondary to renin deficiency
- Isolated aldosterone deficiency

**With hypertension:**
- Acute alcohol intoxication (toxic effects of alcohol can affect adrenal gland function and therefore secretion of aldosterone)
- Diabetes (impaired conversion of prerenin to renin by damaged kidneys results in decreased aldosterone)
- Excess secretion of deoxycorticosterone (cortisol suppresses production of ACTH, which in turn affects aldosterone secretion)
Turner’s syndrome (25% of cases) (congenital adrenal hyperplasia can result in underproduction of aldosterone and overproduction of androgens)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase aldosterone levels include amiloride, ammonium chloride, angiotensin, angiotensin II, dobutamine, dopamine, endralazine, fenoldopam, hydralazine, hydrochlorothiazide, laxatives (abuse), metcloplamid, nifedipine, opiates, potassium, spironolactone, and zacopride.
- Drugs that may decrease aldosterone levels include atenolol, captopril, carvedilol, cilazapril, enalapril, fadrozole, glycyrrhiza (licorice), ibopamine, indomethacin, lisinopril, nicardipine, NSAIDs, perindopril, ranitidine, saline, sinorphan, and verapamil. Prolonged heparin therapy also decreases aldosterone levels.
- Upright body posture, stress, strenuous exercise, and late pregnancy can lead to increased levels.
- Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when radioimmunoassay is the test method.
- Diet can significantly affect results. A low-sodium diet can increase serum aldosterone, whereas a high-sodium diet can decrease levels. Decreased serum sodium and elevated serum potassium increase aldosterone secretion. Elevated serum sodium and decreased serum potassium suppress aldosterone secretion.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers
- Inform the patient that the test is used to evaluate hypertension and possible hyperaldosteronism.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of known or suspected fluid or electrolyte imbalance, hypertension, renal function, or stage of pregnancy. Note the amount of sodium ingested in the diet over the past 2 wk.
- Obtain a history of the patient’s endocrine and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient.
- Inform the patient that specimen collection takes approximately 5 to 10 min. Inform the patient that multiple specimens may be required. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Inform the patient that the required position, supine/lying down or upright/sitting up, must be maintained for 2 hr before specimen collection. Some health care providers (HCP) may also order administration of furosemide (40–80 mg) upon arising.
- The patient should be on a normal-sodium diet (1 to 2 g of sodium per day) for 2 to 4 wk before the test. Protocols may vary from facility to facility.
- Under medical direction, the patient should avoid diuretics, antihypertensive drugs and herbs, and cyclic progestogens and estrogens for 2 to 4 wk before the test.

**INTRATEST:**
- Ensure that the patient has complied with dietary, medication, and pretesting preparations regarding activity.
If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, time of collection, patient position (upright or supine), and exact source of specimen (peripheral versus arterial). Perform a venipuncture after the patient has been in the upright (sitting or standing) position for 2 hr. If a supine specimen is requested on an inpatient, the specimen should be collected early in the morning before rising.

Remove the needle, and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen on ice to the laboratory for processing and analysis.

**POST-TEST:**

A written report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet, medication, and activity as directed by the HCP.

Instruct the patient to notify the HCP of any signs and symptoms of dehydration or fluid overload related to elevated aldosterone levels or compromised sodium regulatory mechanisms.

**Nutritional considerations:** Aldosterone levels are involved in the regulation of body fluid volume. Educate patients about the importance of proper water balance. Although there is no recommended dietary allowance (RDA) for water, adults need 1 mL/kcal per day. Infants need more water because their basal metabolic heat production is much higher than in adults. Tap water may also contain other nutrients. Water-softening systems replace minerals (e.g., calcium, magnesium, iron) with sodium, so caution should be used if a low-sodium diet is prescribed.

**Nutritional considerations:** Because aldosterone levels have an effect on sodium levels, some consideration may be given to dietary adjustment if sodium allowances need to be regulated. Educate patients with low sodium levels that the major source of dietary sodium is table salt. Many foods, such as milk and other dairy products, are also good sources of dietary sodium. Most other dietary sodium is available through consumption of processed foods. Patients who need to follow low-sodium diets should avoid beverages such as colas, ginger ale, Gatorade, lemon-lime sodas, and root beer. Many over-the-counter medications, including antacids, laxatives, analgesics, sedatives, and antitussives, contain significant amounts of sodium. The best advice is to emphasize the importance of reading all food, beverage, and medicine labels. In 1989, the Subcommittee on the 10th Edition of the RDAs established 500 mg as the recommended minimum limit for dietary intake of sodium. There are no RDAs established for potassium, but the estimated minimum intake for adults is 200 mEq/d. Potassium is present in all plant and animal cells, making dietary replacement simple. An HCP or nutritionist should be consulted before considering the use of salt substitutes.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include adrenal gland scan, biopsy kidney, BUN, catecholamines, cortisol, creatinine, glucose, magnesium, osmolality, potassium, protein urine, renin, sodium, and UA.

See the Endocrine and Genitourinary System tables at the back of the book for related tests by body system.
**SYNONYM/ACRONYM:** Alk Phos, ALP and fractionation, heat-stable ALP.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

**REFERENCE VALUE:** (Method: Spectrophotometry for total alkaline phosphatase, inhibition/electrophoresis for fractionation)

Access additional resources at davisplus.fadavis.com
DESCRIPTION: Alkaline phosphatase (ALP) is an enzyme found in the liver, in Kupffer cells lining the biliary tract, and in bones, intestines, and placenta. Additional sources of ALP include the proximal tubules of the kidneys, pulmonary alveolar cells, germ cells, vascular bed, lactating mammary glands, and granulocytes of circulating blood. ALP is referred to as alkaline because it functions optimally at a pH of 9.0. This test is most useful for determining the presence of liver or bone disease. Isoelectric focusing methods can identify 12 isoenzymes of ALP. Certain cancers produce small amounts of distinctive Regan and Nagao ALP isoenzymes. Elevations in three main ALP isoenzymes, however, are of clinical significance: ALP₁ of liver origin, ALP₂ of bone origin, and ALP₃ of intestinal origin (normally only present in individuals with blood types O and B). ALP levels vary by age and gender. Values in children are higher than in adults because of the level of bone growth and development. An immunoassay method is available for measuring bone-specific ALP as an indicator of increased bone turnover and estrogen deficiency in postmenopausal women.

INDICATIONS:
• Evaluate signs and symptoms of various disorders associated with elevated ALP levels, such as biliary obstruction, hepatobiliary disease, and bone disease, including malignant processes
• Differentiate obstructive hepatobiliary tract disorders from hepatocellular disease; greater elevations of ALP are seen in the former
• Determine effects of renal disease on bone metabolism
• Determine bone growth or destruction in children with abnormal growth patterns

RESULT:
Increased in:
• Alkaline phosphatase is released from any damaged cell in which it is stored so diseases of the bone, biliary tract, and liver that cause cellular destruction demonstrate elevated alkaline phosphatase levels.
• Liver disease:
  Biliary atresia
  Biliary obstruction (acute cholecystitis, choledolithiasis, intrahepatic cholestasis of pregnancy, primary biliary cirrhosis)
  Cancer
  Chronic active hepatitis
  Cirrhosis
  Diabetes (diabetic hepatic lipodosis)
  Extrahepatic duct obstruction
  Granulomatous or infiltrative liver diseases (sarcoidosis, amyloidosis, TB)
  Infectious mononucleosis
  Intrahepatic biliary hypoplasia
  Toxic hepatitis
  Viral hepatitis
• Bone disease:
  Healing fractures
  Metabolic bone diseases (rickets, osteomalacia)
  Metastatic tumors in bone
  Osteogenic sarcoma
  Osteoporosis
  Paget’s disease (osteitis deformans)
• Other conditions:
  Advanced pregnancy (from placenta and new bone growth; marked decline is seen with placental insufficiency and imminent fetal demise)
  Cancer of the breast, colon, gallbladder, lung, or pancreas
  Congestive heart failure
  Familial hyperphosphatemia
  Hyperparathyroidism
  Perforated bowel
  Pneumonia
ALKALINE PHOSPHATASE AND ISOENZYMES

Pulmonary and myocardial infarctions
Pulmonary embolism
Ulcerative colitis

Decreased in:
• Anemia (severe)
• Celiac disease
• Folic acid deficiency
• HIV-1 infection
• Hypervitaminosis D
• Hypophosphatasia (congenital and rare; there is insufficient phosphorus available to make ALP)
• Hypothyroidism (characteristic in infantile and juvenile cases)
• Nutritional deficiency of zinc or magnesium
• Pernicious anemia
• Scurvy
• Vitamin C deficiency
• Whipple’s disease
• Zollinger-Ellison syndrome

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may increase ALP levels by causing cholestasis include anabolic steroids, erythromycin, estrogens, ethionamide, gold salts, imipramine, interleukin-2, mercaptopurine, nitrofurans, oral contraceptives, penicillins, phenothiazines, prooxyphene, sulfonamides, and tolbutamide.
• Drugs that may increase ALP levels by causing hepatocellular damage include acetaminophen (toxic), amiodarone, anticonvulsants, asparaginase, bromocriptine, captopril, cephalosporins, chloramphenicol, enflurane, ethionamide, foscarnet, gentamicin, indomethacin, lincomycin, methylldopa, naproxen, nitrofurans, probenecid, procainamide, progesterone, ranitidine, and verapamil.
• Drugs that may cause an overall decrease in ALP levels include alendrolate, azathioprine, clofibrate, estrogens with estrogen replacement therapy, and theophylline.
• Hemolyzed specimens may cause falsely elevated results.
• Elevations of ALP may occur if the patient is nonfasting, usually 2 to 4 hr after a fatty meal, and especially if the patient is a Lewis-positive secretor of blood group B or O.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to assess liver function.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s hepatobiliary and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
• Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:
• If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
• Instruct the patient to cooperate fully and to follow directions. Direct the

Access additional resources at davisplus.fadavis.com
patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding and hematoma formation and secure gauze with adhesive bandage.

Prompely transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A written report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

**Nutritional considerations:** Increased ALP levels may be associated with liver disease. Dietary recommendations may be indicated and vary depending on the severity of the condition. A low-protein diet may be in order if the patient’s liver has lost the ability to process the end products of protein metabolism. A diet of soft foods may be required if esophageal varices have developed. Ammonia levels may be used to determine whether protein should be added to or reduced from the diet. Patients should be encouraged to eat simple carbohydrates and emulsified fats (as in homogenized milk or eggs), as opposed to complex carbohydrates (e.g., starch, fiber, and glycogen [animal carbohydrates]) and complex fats, which require additional bile to emulsify them so that they can be used. The cirrhotic patient should be carefully observed for the development of ascites, in which case fluid and electrolyte balance requires strict attention.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include acetaminophen, ALT, albumin, ammonia, anti-DNA antibodies, AMA/ASMA, ANA, α₁-antitrypsin, α₁-antitrypsin phenotyping, AST, bilirubin, biopsy bone, biopsy liver, bone scan, BMD, calcium, ceruloplasmin, collagen cross-linked telopeptides, C3 and C4, complements, copper, ERCP, GGT, hepatitis antigens and antibodies, hepatobiliary scan, KUB studies, magnesium, MRI abdomen, osteocalcin, PTH, phosphorus, potassium, protein, protein electrophoresis, PT/INR, salicylate, sodium, US liver, vitamin D, and zinc.

See the Hepatobiliary and Musculoskeletal System tables at the back of the book for related tests by body system.

### Alternate Scoring Method (ASM): Increasing Levels of Allergy Sensitivity

- **Monitor response to desensitization procedures**
- **Test for allergens when skin testing is inappropriate, such as in infants**
- **Test for allergens when there is a known history of allergic reaction to skin testing**
- **Test for specific allergic sensitivity before initiating immunotherapy or desensitization shots**
- **Test for specific allergic sensitivity when skin testing is unreliable (patients taking long-acting antihistamines may have false negative skin test)**

### DESCRIPTION:

Allergen-specific immunoglobulin E (IgE) or a radioallergosorbent test (RAST) is generally requested for groups of allergens commonly known to incite an allergic response in the affected individual. The test is based on the use of a radio-labeled anti-IgE reagent to detect IgE in the patient’s serum, produced in response to specific allergens. The panels include allergens such as animal dander, antibiotics, dust, foods, grasses, insects, trees, mites, molds, venom, and weeds. Allergen testing is useful for evaluating the cause of hay fever, extrinsic asthma, atopic eczema, respiratory allergies, and potentially fatal reactions to insect venom, penicillin, and other drugs or chemicals. RAST is an alternative to skin test anergy and provocation procedures, which can be inconvenient, painful, and potentially hazardous to patients.

### INDICATIONS:

- Evaluate patients who refuse to submit to skin testing or who have generalized dermatitis or other dermatopathic conditions

### RESULT:

Different scoring systems are used in the interpretation of RAST results.

**Increased in:**

- **IgE is the antibody that primarily responds to conditions that stimulate an allergic response and elevations are expected**
- Allergic rhinitis
- Anaphylaxis
- Asthma (exogenous)
- Atopic dermatitis
- *Echinococcus* infection
- Eczema
- Hay fever
- Hookworm infection
- Latex allergy

Access additional resources at davisplus.fadavis.com
• Schistosomiasis
• Visceral larva migrans

Decreased in:
• Asthma (endogenous)
• Pregnancy
• Radiation therapy

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Recent radioactive scans or radiation within 1 week of the test can interfere with test results when radioimmunoassay is the test method.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to identify types of allergens that may be responsible for causing an allergic response.
• Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient's immune and respiratory system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Note any recent procedures that can interfere with test results.
• Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
• There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:
• If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

• Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
• Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Indicate the specific allergen group to be tested on the specimen requisition. Perform a venipuncture.
• Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding and hematoma formation and secure gauze with adhesive bandage.
• Promptly transport the specimen to the laboratory for processing and analysis.

A written report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Nutritional considerations should be given to diet if food allergies are present. Lifestyle adjustments may be necessary depending on the specific allergens identified.

Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.

Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Related tests include arterial/alveolar oxygen ratio, blood gases, complete blood count, eosinophil count, fecal analysis, hypersensitivity pneumonitis, IgE, and PFT.

See the Immune and Respiratory System tables for related tests by body system.

RELATED MONOGRAPHS:
Alveolar/Arterial Gradient and Arterial/Alveolar Oxygen Ratio

SYNONYM/ACRONYM: Alveolar-arterial difference, A/a gradient, a/A ratio.

SPECIMEN: Arterial blood (1 mL) collected in a heparinized syringe. Specimen should be transported tightly capped and in an ice slurry.

REFERENCE VALUE: (Method: Selective electrodes that measure pO\textsubscript{2} and pCO\textsubscript{2})

DESCRIPTION: A test of the ability of oxygen to diffuse from the alveoli into the lungs is of use when assessing a patient’s level of oxygenation. This test can help identify the cause of hypoxemia (low oxygen levels in the blood) and intrapulmonary shunting that might result from one of the following three situations: ventilated alveoli without perfusion, unventilated alveoli with perfusion, or collapse of alveoli and associated blood vessels. Information regarding the alveolar/arterial (A/a) gradient can be estimated indirectly using the partial pressure of oxygen (pO\textsubscript{2}) (obtained from blood gas analysis) in a simple mathematical formula:

\[
A/a \text{ gradient} = \text{pO}_2 \text{ in alveolar air (estimated)} - \text{pO}_2 \text{ in arterial blood (measured)}
\]

An estimate of alveolar pO\textsubscript{2} is accomplished by subtracting the water vapor pressure from the barometric pressure, multiplying the resulting pressure by the fraction of inspired oxygen (FIO\textsubscript{2}; percentage of oxygen the patient is breathing), and subtracting this from 1.25 times the arterial partial pressure of carbon dioxide (pCO\textsubscript{2}). The gradient is obtained by subtracting the patient’s arterial pO\textsubscript{2} from the calculated alveolar pO\textsubscript{2}:

\[
\text{Alveolar } \text{pO}_2 = [(\text{barometric pressure} - \text{water vapor pressure}) \times \text{FIO}_2] - [1.25 \times \text{pCO}_2]
\]

\[
A/a \text{ gradient} = \text{arterial } \text{pO}_2 \text{ (measured)} - \text{alveolar } \text{pO}_2 \text{ (estimated)}
\]

The arterial/alveolar (a/A) ratio reflects the percentage of alveolar pO\textsubscript{2} that is contained in arterial pO\textsubscript{2}. It is calculated by dividing the arterial pO\textsubscript{2} by the alveolar pO\textsubscript{2}:

\[
a/A = \frac{\text{paO}_2}{\text{pAO}_2}
\]

The A/a gradient increases as the concentration of oxygen the patient inspires increases. If the gradient is abnormally high, either there is a problem with the ability of oxygen to pass across the alveolar membrane or oxygenated blood is being mixed with
nonoxygenated blood. The a/A ratio is not dependent on FIO₂; it does not increase with a corresponding increase in inhaled oxygen. For patients on a mechanical ventilator with a changing FIO₂, the a/A ratio can be used to determine if oxygen diffusion is improving.

INDICATIONS:
• Assess intrapulmonary or coronary artery shunting
• Assist in identifying the cause of hypoxemia

RESULT:
Increased in:
• Acute respiratory distress syndrome (ARDS) (due to thickened edematous alveoli)
• Atelectasis (due to mixing oxygenated and unoxygenated blood)
• Arterial-venous shunts (due to mixing oxygenated and unoxygenated blood)
• Bronchospasm
• Chronic obstructive pulmonary disease
• Congenital cardiac septal defects (due to mixing oxygenated and unoxygenated blood)
• Underventilated alveoli (mucus plugs)
• Pneumothorax
• Pulmonary edema (due to thickened edematous alveoli)
• Pulmonary embolus
• Pulmonary fibrosis (due to thickened edematous alveoli)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Specimens should be collected before administration of oxygen therapy or antihistamines.
• The temperature of the patient should be noted and reported to the laboratory if significantly elevated or depressed so that measured values can be corrected to actual body temperature.
• Exposure of sample to room air affects test results.
• Values normally increase with increasing age (see monograph titled “Blood Gases”).
• Samples for A/a gradient evaluation are obtained by arterial puncture, which carries a risk of bleeding, especially in patients with bleeding disorders or who are taking medications for a bleeding disorder.
• Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results. Specimens should always be transported to the laboratory as quickly as possible after collection. Delay in transport of the sample or transportation without ice may affect test results.

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to assess effective delivery of oxygen by comparing the difference between oxygen levels in the arteries and the alveoli of the lungs.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
• Obtain a history of the patient’s cardiovascular and respiratory systems, especially any bleeding disorders and other symptoms, as well as results of previously performed laboratory tests, diagnostic and surgical procedures.
• Note any recent procedures that can interfere with test results.
• Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the
appropriate number of days prior to a surgical procedure.

- Indicate the type of oxygen, mode of oxygen delivery, and delivery rate as part of the test requisition process. Wait 30 min after a change in type or mode of oxygen delivery or rate for specimen collection.

- Review the procedure with the patient, and advise rest for 30 min before specimen collection. Address concerns about pain and explain that an arterial puncture may be painful. The site may be anesthetized with 1% to 2% lidocaine before puncture. Inform the patient that specimen collection usually takes 10 to 15 min. The person collecting the specimen should be notified beforehand if the patient is receiving anticoagulant therapy, or taking aspirin or other natural products that may prolong bleeding from the puncture site.

- If the sample is to be collected by radial artery puncture, perform an Allen test before puncture to ensure that the patient has adequate collateral circulation to the hand. The modified Allen test is performed as follows: extend the patient’s wrist over a rolled towel. Ask the patient to make a fist with the hand extended over the towel. Use the second and third fingers to locate the pulses of the ulnar and radial arteries on the palmar surface of the wrist. (The thumb should not be used to locate these arteries because it has a pulse.) Compress both arteries, and ask the patient to open and close the fist several times until the palm turns pale. Release pressure on the ulnar artery only. Color should return to the palm within 5 sec if the ulnar artery is functioning. This is a positive Allen test, and blood gases may be drawn from the radial artery site. The Allen test should then be performed on the opposite hand. The hand to which color is restored fastest has better circulation and should be selected for specimen collection.

- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- There are no food, fluid, or medication restrictions unless by medical direction.

- Prepare an ice slurry in a cup or plastic bag to have ready for immediate transport of the specimen to the laboratory.

**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection.

- Perform an arterial puncture, and collect the specimen in an air-free heparinized syringe. There is no demonstrable difference in results between samples collected in plastic syringes and samples collected in glass syringes. It is very important that no room air be introduced into the collection container, because the gases in the room and in the sample will begin equilibrating immediately. The end of the syringe must be stoppered immediately after the needle is withdrawn and removed from the puncture site. Apply a pressure dressing over the puncture site. Samples should be mixed by gentle rolling of the syringe to ensure proper mixing of the heparin with the sample, which will prevent the formation of small clots leading to rejection of the sample. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag. Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A written report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

- Pressure should be applied to the puncture site for at least 5 min in the unanticoagulated patient and for at least 15 min in the case of a patient receiving anticoagulant therapy. Observe puncture site for bleeding or hematoma formation. Apply pressure bandage.
Teach the patient breathing exercises to assist with the appropriate exchange of oxygen and carbon dioxide.
Administer oxygen, if appropriate.
Teach the patient how to properly use incentive spirometry or nebulizer, if ordered.
Intervene appropriately for hypoxia and ventilatory disturbances.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include allergen-specific IgE, α1-antitrypsin, α1-antitrypsin phenotyping, blood gases, chest x-ray, D-dimer, echocardiography, eosinophil count, fibrinogen, hypersensitivity pneumonitis, IgE, potassium, PFT, and sodium.
See the Cardiovascular and Respiratory System tables in the back of the book for related tests by body system.

---

**Alzheimer’s Disease Markers**

**SYNONYM/ACRONYM:** CSF tau protein and β-amyloid-42, AD.

**SPECIMEN:** Cerebrospinal fluid (CSF) (1 to 2 mL) collected in a plain plastic conical tube.

**REFERENCE VALUE:** (Method: Enzyme-linked immunosorbent assay) Simultaneous tau protein and β-amyloid-42 measurements in CSF are used in conjunction as biochemical markers of Alzheimer’s disease (AD). Scientific studies indicate that a combination of elevated tau protein and decreased β-amyloid-42 protein levels are consistent with the presence of AD. Values are highly dependent on the reagents and standards used in the assay. Ranges vary among laboratories; the testing laboratory should be consulted for interpretation of results.

**DESCRIPTION:** AD is the most common cause of dementia in the elderly population. AD is a disorder of the central nervous system (CNS) that results in progressive and profound memory loss followed by loss of cognitive abilities and death. It may follow years of progressive formation of amyloid plaques and brain tangles, or it may appear as an early-onset form of the disease. Two recognized pathologic features of AD are neurofibrillary tangles and amyloid plaques found in the brain. Abnormal forms of the microtubule-associated tau protein are the main component of the classic neurofibrillary tangles found in patients with AD. Tau protein concentration is believed to reflect the number of neurofibrillary tangles and may be an indication of the severity of the disease. β-amyloid-42 is a free-floating protein normally present in CSF. It is believed to accumulate in the CNS of patients with AD, causing...
the formation of amyloid plaques on brain tissue. The result is that these patients have lower CSF values compared to age-matched non-AD control subjects. Recent research utilizing bio-barcode technology is investigating an association between increased levels of amyloid-beta-derived diffusible ligand (ADDL) in CSF and progression of AD.

**INDICATIONS:**
- Assist in establishing a diagnosis of AD

**RESULT:**

**Decreased in:**
- \(\beta\)-Amyloid-42 is decreased up to 50% of normal control
  - AD (accumulation in brain with corresponding decrease in CSF)
  - Creutzfeldt-Jakob disease

**Increased in:**
- Tau protein is increased
  - AD

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Some patients with AD may have normal levels of tau protein because of an insufficient number of neurofibrillary tangles.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in predictive testing for or confirmation of Alzheimer's disease, and to monitor progression of and therapy for the disease.
Record baseline vital signs, and assess neurologic status. Protocols may vary from facility to facility.

To perform a lumbar puncture, position the patient in the knee-chest position at the side of the bed. Provide pillows to support the spine or for the patient to grasp. The sitting position is an alternative. In this position, the patient must bend the neck and chest to the knees.

Prepare the site (usually between L3 and L4 or L4 and L5) with povidone-iodine, and drape the area.

A local anesthetic is injected. Using sterile technique, the HCP inserts the spinal needle through the spinous processes of the vertebrae and into the subarachnoid space. The stylet is removed. CSF drips from the needle if it is properly placed.

Attach the stopcock and manometer, and measure initial CSF pressure. Normal pressure for an adult in the lateral recumbent position is 90 to 180 mm H2O. These values depend on the body position and are different in a horizontal or sitting position.

If the initial pressure is elevated, the HCP may perform Queckenstedt’s test. To perform this test, apply pressure to the jugular vein for about 10 sec. CSF pressure usually rises in response to the occlusion, then rapidly returns to normal within 10 sec after the pressure is released. Sluggish response may indicate CSF obstruction.

Obtain CSF, and place in specimen tubes. Take a final pressure reading, and remove the needle. Clean the puncture site with an antiseptic solution, and apply a small bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A written report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

After lumbar puncture, monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take the temperature every 4 hr for 24 hr. Compare with baseline values. Protocols may vary from facility to facility.

Administer fluids, if permitted, to replace lost CSF and help prevent or relieve headache, which is a side effect of lumbar puncture.

Check the puncture site for leakage, and frequently monitor body signs, such as temperature and blood pressure.

Position the patient flat, either on the back or abdomen, although some HCPs allow 30 degrees of elevation. Maintain this position for 8 hr. Changing position is acceptable as long as the body remains horizontal.

Observe the patient for neurologic changes, such as altered level of consciousness, change in pupils, reports of tingling or numbness, and irritability.

Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient and family members regarding access to counseling and other supportive services. Provide contact information if desired, for the Alzheimer’s Association (www.alz.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include evoked brain potentials, MRI brain, and PET scan brain.

See the Musculoskeletal System table at the back of the book for related tests by body system.
**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Plasma (1 mL) collected in a green-top (heparin) tube.

*(table continues on page 36)*
DESCRIPTION: Testing for specific aminoacidopathies is generally performed on infants after an initial screening test with abnormal results. Certain congenital enzyme deficiencies interfere with normal amino acid metabolism and cause excessive accumulation of or deficiencies in amino acid levels. The major genetic disorders include phenylketonuria, tyrosinuria, and alcaptonuria, a defect in the phenylalanine-tyrosine conversion pathway. Renal aminoaciduria is also associated with conditions marked by defective tubular reabsorption from congenital disorders, such as hereditary fructose intolerance, cystinuria, and Hartnup disease. Early diagnosis and treatment of certain aminoacidopathies can prevent mental retardation, reduced growth rates, and various unexplained symptoms. In most cases when plasma levels are elevated, urine levels are also elevated. Amino acid quantitation from plasma specimens is more informative, less variable, and less
prone to analytic interference than from urine specimens. Urine specimens may be required to assist in the identification of disorders involving defective renal transport, where elevated levels are only manifested in the urine. Values are age-dependent. Amino acid concentrations demonstrate a significant circadian rhythm with values being lowest in the morning and highest in midafternoon.

**INDICATIONS:**
- Assist in the detection of non-inherited disorders evidenced by elevated amino acid levels
- Detect congenital errors of amino acid metabolism

**RESULT:**

**Increased in:**
- Increased amino acid accumulation (total amino acids) occurs when a specific enzyme deficiency prevents its catabolism, with liver disease, or when there is impaired clearance by the kidneys:
  - Aminoacidopathies (usually inherited; specific amino acids are implicated)
  - Burns
  - Diabetes
  - Fructose intolerance (hereditary)
  - Malabsorption
  - Renal failure (acute or chronic)
  - Reye’s syndrome
  - Severe liver damage
  - Shock

**Decreased in:**
- Decreased (total amino acids) in conditions that result in increased renal excretion or insufficient protein intake or synthesis:
  - Adrenocortical hyperfunction
  - Carcinoid syndrome
  - Fever
  - Glomerulonephritis
  - Hartnup disease
  - Huntington’s chorea
  - Malnutrition

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase plasma amino acid levels include amino acids, bismuth salts, glucocorticoids, levarterenol, and 11-oxysteroids.
- Drugs that may decrease plasma amino acid levels include diethylstilbestrol, epinephrine, insulin, and progesterone.
- Amino acids exhibit a strong circadian rhythm; values are highest in the afternoon and lowest in the morning. Protein intake does not influence diurnal variation but significantly affects absolute concentrations.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
Review the procedure with the patient (and/or caregiver). Inform the patient (and/or caregiver) that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

**Sensitivity to social and cultural issues**, is important in providing psychological support before, during, and after the procedure.

Instruct the patient to fast for 12 hr prior to the procedure.

There are no fluid or medication restrictions unless by medical direction.

**INTRATEST:**

- Ensure that the patient has complied with dietary and other pretesting preparations; assure that food has been restricted for at least 12 hr prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient (and/or caregiver) to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement. The caregiver may assist in preventing unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient (and/or caregiver).

- Instruct the patient to resume usual diet as directed by the HCP.
- **Nutritional considerations:** Instruct the patient (and/or caregiver) in special dietary modifications, as appropriate to treat deficiency, or refer caregiver to a qualified nutritionist. Amino acids are classified as essential (i.e., must be present simultaneously in sufficient quantities); conditionally or acquired essential (i.e., under certain stressful conditions, they become essential); and nonessential (i.e., can be produced by the body, when needed, if diet does not provide them). Essential amino acids include lysine, threonine, histidine, isoleucine, methionine, phenylalanine, tryptophan, and valine. Conditionally essential amino acids include cysteine, tyrosine, arginine, citrulline, taurine, and carnitine. Nonessential amino acids include alanine, glutamic acid, aspartic acid, glycine, serine, proline, glutamine, and asparagine. A high intake of specific amino acids can cause other amino acids to become essential.
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient (and/or caregiver) regarding access to genetic or other counseling services. Provide contact information, if desired, for the March of Dimes (www.marchofdimes.com) or the state department of health newborn screening program.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ammonia and urine amino acid screen.
- See the Genitourinary, Hepatobiliary, and Reproductive System tables at the back of the book for related tests by body system.
SYNONYM/ACRONYM: N/A.

SPECIMEN: Urine (10 mL) from a random or timed specimen collected in a clean plastic collection container with hydrochloric acid as a preservative.

REFERENCE VALUE: (Method: Chromatography) There are numerous amino acids. The following table includes those most frequently screened. All units are nanomoles per milligram (nmol/mg) creatinine.

Access additional resources at davisplus.fadavis.com
RESULT:

**Increased in:**

- Increased amino acid accumulation (total amino acids) occurs when a specific enzyme deficiency prevents its catabolism or when there is impaired clearance by the kidneys:
  - **Primary causes** *(inherited):*
    - Aminoaciduria (specific)
    - Cystinosis *(may be masked because of decreased glomerular filtration rate, so values may be in normal range)*
    - Fanconi’s syndrome
    - Fructose intolerance
  - **Secondary causes** *(noninherited):*
    - Acute leukemia
    - Chronic renal failure *(reduced GFR)*
    - Diabetic ketosis
    - Epilepsy *(transient increase due to disturbed renal function during grand mal seizure)*

DESCRIPTION: δ-Aminolevulinic acid (δ-ALA) is involved in the formation of porphyrins. Toxins including alcohol, lead, and other heavy metals can inhibit porphyrin synthesis. Accumulated δ-ALA is excreted in urine. Symptoms of the acute phase of intermittent porphyrrias include abdominal pain, nausea, vomiting, neuromuscular signs and symptoms, constipation, and occasionally psychotic behavior. Hemolytic anemia may also exhibit during the acute phase. δ-ALA is a test of choice in the diagnosis of acute intermittent porphyria. Although lead poisoning can cause increased urinary excretion, the measurement of δ-ALA is not useful to indicate lead toxicity because it is not detectable in the urine until the blood lead level approaches and exceeds 40 mcg/dL.

INDICATIONS:
• Assist in the diagnosis of porphyrias

RESULT:

Increased in:
• Inhibition of the enzymes involved in porphyrin synthesis results in accumulation of δ-ALA.
  • Acute porphyrias
  • Aminolevulinic acid dehydrase deficiency
  • Hereditary tyrosinemia
  • Lead poisoning

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may increase δ-ALA levels include penicillins.
• Cimetidine may decrease δ-ALA levels.
• Numerous drugs are suspected as potential initiators of attacks.
of acute porphyria, but those classified as unsafe for high-risk individuals include aminopyrine, apronil, barbiturates, chlor-diazepoxide, chlorpropamide, diazepam, dichloralphenazone, ergot preparations, glutethimide, griseofulvin, hydantoin derivatives, isopropyl dipryrone, meprobamate, methylldopa, methylsulfonal, methyprylone, oral contraceptives, pentazocine, phenytoin, progestogens, succinimide, sulfomethane, and tolbutamide.

Alternative, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container. Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex. Instruct the patient to cooperate fully and to follow directions. Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

Timed Specimen:

Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice. Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started, and add this last voiding to the container. Urinary output should be recorded throughout the collection time.

If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period. Monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun. At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection. If the specimen contains less than what was
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include complete blood count, erythrocyte protoporphyrin (free), lead and porphyrins urine.
- See the Hematopoietic System table in the back of the book for related tests by body system.

**SYNONYM/ACRONYM:** NH₃.

**SPECIMEN:** Plasma (1 mL) collected in completely filled lavender- (EDTA) or green-top (Na or Li heparin) tube. Specimen should be transported tightly capped and in an ice slurry.

**DESCRIPTION:** Blood ammonia (NH₃) comes from two sources: deamination of amino acids during protein metabolism and degradation of proteins by colon bacteria. The liver converts ammonia in the portal blood to urea, which is excreted by the kidneys. When liver function is severely compromised, especially in situations in which decreased hepatocellular function is combined with impaired portal blood flow, ammonia levels rise. Ammonia is potentially toxic to the central nervous system.
INDICATIONS:
- Evaluate advanced liver disease or other disorders associated with altered serum ammonia levels
- Identify impending hepatic encephalopathy with known liver disease
- Monitor the effectiveness of treatment for hepatic encephalopathy, indicated by declining levels
- Monitor patients receiving hyperalimentation therapy

RESULT:

Increased in:
- Gastrointestinal hemorrhage (decreased blood volume prevents ammonia from reaching the liver to be metabolized)
- Genitourinary tract infection with distention and stasis (decreased renal excretion; levels accumulate in the blood)
- Hepatic coma (insufficient functioning liver cells to metabolize ammonia; levels accumulate in the blood)
- Inborn enzyme deficiency (inability to metabolize ammonia)
- Liver failure, late cirrhosis (insufficient functioning liver cells to metabolize ammonia)
- Reye’s syndrome (insufficient functioning liver cells to metabolize ammonia)
- Total parenteral nutrition (ammonia is generated from protein metabolism)

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs that may increase ammonia levels include asparaginase, chlor-thiazide, fibrin hydrolysate, furosemide, hydroflumethiazide, thiazides, and valproic acid.
- Drugs/organisms that may decrease ammonia levels include diphenhydramine, kanamycin, neomycin, tetracycline, and Lactobacillus acidophilus.
- Hemolysis falsely increases ammonia levels because intracellular ammonia levels are three times higher than plasma.
- Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results. The specimen should be collected on ice; the collection tube should be filled completely, and then kept tightly stoppered. Ammonia increases rapidly in the collected specimen, so analysis should be performed within 20 min of collection.

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess liver function, particularly in the diagnosis of urea cycle deficiencies in neonates and the identification of Reye’s syndrome.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s gastrointestinal, genitourinary, and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues; as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.
**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe the venipuncture site for bleeding or hematoma formation and secure the gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- **Nutritional considerations:** Increased ammonia levels may be associated with liver disease. Dietary recommendations may be indicated, depending on the severity of the condition. A low-protein diet may be in order if the patient’s liver has lost the ability to process the end products of protein metabolism. A diet of soft foods may be required if esophageal varices have developed. Ammonia levels may be used to determine whether protein should be added to or reduced from the diet. Patients should be encouraged to eat simple carbohydrates and emulsified fats (as in homogenized milk or eggs), as opposed to complex carbohydrates (e.g., starch, fiber, and glycogen [animal carbohydrates]) and complex fats, which would require additional bile to emulsify them so that they could be used. The cirrhotic patient should be carefully observed for the development of ascites, in which case fluid and electrolyte balance requires strict attention.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include acetaminophen, ALT, albumin, anion gap, AST, bilirubin, biopsy liver, blood gases, BUN, blood calcium, complete blood count, CT biliary tract and liver, CT pelvis, cystoscopy, EGD, electrolytes, GI blood loss scan, glucose, IVP, MRI pelvis, ketones, lactic acid, Meckel’s scan, osmolality, protein, PT/INR, uric acid, and US pelvis.
- See the Gastrointestinal, Genitourinary, and Hepatobiliary System tables at the back of the book for related tests by body system.
**REFERENCE VALUE:** (Method: Macroscopic observation of fluid for color and appearance, immunochemiluminometric assay [ICMA] for α₁-fetoprotein, electrophoresis for acetylcholinesterase, spectrophotometry for creatinine and bilirubin, chromatography for lecithin/sphingomyelin [L/S] ratio and phosphatidylglycerol, tissue culture for chromosome analysis, dipstick for leukocyte esterase, and automated cell counter for white blood cell count and lamellar bodies)

*MoM = multiples of the median.

**DESCRIPTION:** Amniotic fluid is formed in the membranous sac that surrounds the fetus. The total volume of fluid at term is 500 to 2500 mL. In amniocentesis, fluid is obtained by ultrasound-guided needle aspiration from the amniotic sac. This procedure is generally performed between 14 and 16 weeks’ gestation for accurate interpretation of test results, but it also can be done between 26 and 35 weeks’ gestation if fetal distress is suspected. Amniotic fluid is tested to identify genetic and neural tube defects, hemolytic diseases of the newborn, fetal infection, fetal renal malfunction, or maturity of the fetal lungs (see monograph titled “Lecithin/Sphingomyelin Ratio”). Several rapid tests are also used to differentiate amniotic fluid from other body fluids in a vaginal specimen when premature rupture of membranes (PROM) is suspected.

A vaginal swab obtained from the posterior vaginal pool can be used to perform a rapid, waived procedure to aid in the assessment of PROM. Nitrazine paper impregnated with an indicator dye will produce a color change indicative of vaginal pH. Normal vaginal pH is acidic (4.5–6.0) and the color of the paper will not change. Amniotic fluid has an alkaline pH (7.1–7.3) and the paper will turn a blue color. False positive results occur in the presence of semen, blood, alkaline urine, vaginal infection, or if the patient is receiving antibiotics. The amniotic fluid crystallization or Fern test is based on the observation of a fern pattern when amniotic fluid is placed on a glass slide and allowed to air dry. The fern pattern is due to the protein and sodium chloride content of the amniotic fluid. False positive results occur in the presence of blood urine or cervical
mucus. Both of these tests can produce false negative results if only a small amount of fluid is leaked. The reliability of results is also significantly diminished with the passage of time (greater than 24 hr). AmniSure is an immunoassay that can be performed on a vaginal swab sample. It is a rapid test that detects placental alpha microglobulin-1 protein (PAMG-1), which is found in high concentrations in amniotic fluid. AmniSure does not demonstrate the high frequency of false positive and negative results inherent with the pH and fern tests.

**INDICATIONS:**

- Assist in the diagnosis of (in utero) metabolic disorders, such as cystic fibrosis; or errors of lipid, carbohydrate, or amino acid metabolism.
- Detect infection secondary to ruptured membranes.
- Detect fetal ventral wall defects.
- Determine fetal maturity when preterm delivery is being considered. Fetal maturity is indicated by an L/S ratio of 2:1 or greater (see monograph titled “Lecithin/Sphingomyelin Ratio”).
- Determine fetal gender when the mother is a known carrier of a sex-linked abnormal gene that could be transmitted to male offspring, such as hemophilia or Duchenne’s muscular dystrophy.
- Determine the presence of fetal distress in late-stage pregnancy.
- Evaluate fetus in families with a history of genetic disorders, such as Down syndrome, Tay-Sachs disease, chromosome or enzyme anomalies, or inherited hemoglobinopathies.
- Evaluate fetus in mothers of advanced maternal age (some of the aforementioned tests are routinely requested in mothers age 35 and older).
- Evaluate fetus in mothers with a history of miscarriage or stillbirth.
- Evaluate known or suspected hemolytic disease involving the fetus in an Rh-sensitized pregnancy, indicated by rising bilirubin levels, especially after the 30th wk of gestation.
- Evaluate suspected neural tube defects, such as spina bifida or myelomeningocele, as indicated by elevated α-Fetoprotein (see monograph titled “α-Fetoprotein” for information related to triple-marker testing).

**RESULT:**

- Yellow, green, red, or brown fluid indicates the presence of bilirubin, blood (fetal or maternal), or meconium, which indicate fetal distress or death, hemolytic disease, or growth retardation.
- Elevated bilirubin levels indicate fetal hemolytic disease or intestinal obstruction. Measurement of bilirubin is not usually performed before 20 to 24 weeks’ gestation because no action can be taken before then. The severity of hemolytic disease is graded by optical density (OD) zones: A value of 0.28 to 0.46 OD at 28 to 31 weeks’ gestation indicates mild hemolytic disease, which probably will not affect the fetus; 0.47 to 0.90 OD indicates a moderate effect on the fetus; and 0.91 to 1.0 OD indicates a significant effect on the fetus. A trend of increasing values with serial measurements may indicate the need for intrauterine transfusion or early delivery, depending on the fetal age. After 32 to 33 weeks’ gestation, early delivery is preferred over intrauterine transfusion, because early delivery is more effective in providing the required care to the neonate.
• Creatinine concentration greater than 2.0 mg/dL indicates fetal maturity (at 36 to 37 wk) if maternal creatinine is also within the expected range. This value should be interpreted in conjunction with other parameters evaluated in amniotic fluid and especially with the L/S ratio, because normal lung development depends on normal kidney development.

• An L/S ratio less than 2:1 and absence of phosphatidylglycerol at term indicate fetal lung immaturity and possible respiratory distress syndrome. The expected L/S ratio for the fetus of an insulin-dependent diabetic mother is higher (3.5:1).

• Lamellar bodies are specialized alveolar cells in which lung surfactant is stored. They are approximately the size of platelets. Their presence in sufficient quantities is an indicator of fetal lung maturity.

• Elevated α₁-fetoprotein levels and presence of acetylcholinesterase indicate a neural tube defect (see monograph titled “α₁-Fetoprotein”). Elevation of acetylcholinesterase is also indicative of ventral wall defects.

• Abnormal karyotype indicates genetic abnormality (e.g., Tay-Sachs disease, mental retardation, chromosome or enzyme anomalies, and inherited hemoglobinopathies). (See monograph titled “Chromosome Analysis, Blood.”)

• Elevated white blood cell count and positive leukocyte esterase are indicators of infection.

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Bilirubin may be falsely elevated if maternal hemoglobin or meconium is present in the sample; fetal acidosis may also lead to falsely elevated bilirubin levels.

• Bilirubin may be falsely decreased if the sample is exposed to light or if amniotic fluid volume is excessive.

• Maternal serum creatinine should be measured simultaneously for comparison with amniotic fluid creatinine for proper interpretation. Even in circumstances in which the maternal serum value is normal, the results of the amniotic fluid creatinine may be misleading. A high fluid creatinine value in the fetus of a diabetic mother may reflect the increased muscle mass of a larger fetus. If the fetus is big, the creatinine may be high, and the fetus may still have immature kidneys.

• Contamination of the sample with blood or meconium or complications in pregnancy may yield inaccurate L/S ratios.

• α₁-Fetoprotein and acetylcholinesterase may be falsely elevated if the sample is contaminated with fetal blood.

• Karyotyping cannot be performed under the following conditions: (1) failure to promptly deliver samples for chromosomal analysis to the laboratory performing the test, or (2) improper incubation of the sample, which causes cell death.

• Amniocentesis is contraindicated in women with a history of premature labor or incompetent cervix. It is also contraindicated in the presence of placenta previa or abruptio placentae.

PRETEST:

NURSING IMPLICATIONS
AND PROCEDURE

Positively identify the patient using at least two unique identifiers before providing care, treatment, or services. Inform the patient that the test is used to evaluate fetal well-being.
Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.

Obtain a history of the patient’s reproductive system, previous pregnancies, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Include any family history of genetic disorders such as cystic fibrosis, Duchenne’s muscular dystrophy, hemophilia, sickle cell disease, Tay-Sachs disease, thalassemia, and trisomy 21. Obtain maternal Rh type. If Rh-negative, check for prior sensitization. A standard dose of Rh₁(D) immune globulin Rhogam IM or Rhophylac IM or IV is indicated after amniocentesis; repeat doses should be considered if repeated amniocentesis is performed.

Note any recent procedures that can interfere with test results.

Record the date of the last menstrual period and determine the pregnancy weeks’ gestation and expected delivery date.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Warn the patient that normal results do not guarantee a normal fetus. Assure the patient that precautions to avoid injury to the fetus will be taken by localizing the fetus with ultrasound. Address concerns about pain and explain that, during the transabdominal procedure, any discomfort associated with a needle biopsy will be minimized with local anesthetics. If the patient is less than 20 weeks’ gestation, instruct her to drink extra fluids 1 hr before the test and to refrain from urination. The full bladder assists in raising the uterus up and out of the way to provide better visualization during the ultrasound procedure. Patients who are at 20 weeks’ gestation or beyond do not need to drink extra fluids and should void before the test, because an empty bladder is less likely to be accidentally punctured during specimen collection. Encourage relaxation and controlled breathing during the procedure to aid in reducing any mild discomfort. Inform the patient that specimen collection is performed by a health care provider (HCP) specializing in this procedure and usually takes approximately 20 to 30 min to complete.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. There are no food, fluid, or medication restrictions unless by medical direction.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

Ensure that the patient has a full bladder before the procedure if gestation is 20 wk or less; have patient void before the procedure if gestation is 21 wk or more.

Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date, time of collection, and site location.

Have patient remove clothes below the waist. Assist the patient to a supine position on the exam table with the abdomen exposed. Drape the patient’s legs, leaving the abdomen exposed. Raise her head or legs slightly to promote comfort and to relax the abdominal muscles. If the uterus is large, place a pillow or rolled blanket under the patient’s right side to prevent hypertension caused by great-vessel compression. Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.

Record maternal and fetal baseline vital signs, and continue to monitor throughout the procedure. Monitor for uterine contractions. Monitor fetal vital signs using ultrasound. Protocols may vary from facility to facility.

After the administration of local anesthesia, shave and cleanse the site with an antiseptic solution, and drape the area with sterile towels.

Have emergency equipment readily available.

Observe standard precautions, and follow the general guidelines in Appendix A.
Assess the position of the amniotic fluid, fetus, and placenta using ultrasound.

Assemble the necessary equipment, including an amniocentesis tray with solution for skin preparation, local anesthetic, 10- or 20-mL syringe, needles of various sizes (including a 22-gauge, 5-in. spinal needle), sterile drapes, sterile gloves, and foil-covered or amber-colored specimen collection containers.

Cleanse suprapubic area with an antiseptic solution, and protect with sterile drapes. A local anesthetic is injected. Explain that this may cause a stinging sensation.

A 22-gauge, 5-in. spinal needle is inserted through the abdominal and uterine walls. Explain that a sensation of pressure may be experienced when the needle is inserted. Explain to the patient how to use focused and controlled breathing for relaxation during the procedure.

After the fluid is collected and the needle is withdrawn, apply slight pressure to the site. If there is no evidence of bleeding or other drainage, apply a sterile adhesive bandage to the site.

Monitor the patient for complications related to the procedure (e.g., premature labor, allergic reaction, anaphylaxis).

POST-TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

After the procedure, fetal heart rate and maternal life signs (i.e., heart rate, blood pressure, pulse, and respiration) should be compared with baseline values and closely monitored every 15 min for 30 to 60 min after the amniocentesis procedure. Protocols may vary from facility to facility.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Observe the amniocentesis site for bleeding, inflammation, or hematoma formation.

Instruct the patient in the care and assessment of the amniocentesis site.

Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to keep the site clean and change the dressing as needed.

Instruct the patient to expect mild cramping, leakage of small amount of amniotic fluid, and vaginal spotting for up to 2 days following the procedure. Instruct the patient to report moderate to severe abdominal pain or cramps, change in fetal activity, increased or prolonged leaking of amniotic fluid from abdominal needle site, vaginal bleeding that is heavier than spotting, and either chills or fever.

Instruct the patient to rest until all symptoms have disappeared before resuming normal levels of activity.

Administer standard RhoGAM dose to maternal Rh-negative patients to prevent maternal Rh sensitization should the fetus be Rh-positive.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Encourage the family to seek appropriate counseling if concerned with pregnancy termination, and to seek genetic counseling if a chromosomal abnormality is determined. Decisions regarding elective abortion should take place in the presence of both parents. Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks and difficulties of delivering and raising a developmentally challenged infant, as well as exploring other options (termination of pregnancy or adoption). It is also important to discuss problems the mother and father may experience (guilt, depression, anger) if fetal abnormalities are detected.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that it may be 2 to 4 wk before all results are available. Answer any questions or address any concerns voiced by the patient or family.

Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage her
to review corresponding literature provided by a pharmacist.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**AMYLASE**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

**REFERENCE VALUE:** (Method: Spectrophotometry)

**DESCRIPTION:** Amylase, a digestive enzyme, splits starch into disaccharides. Although many cells have amylase activity (e.g., liver, small intestine, ovaries, skeletal muscles), circulating amylase is derived from the parotid glands and the pancreas. Amylase is a sensitive indicator of pancreatic acinar cell damage and pancreatic obstruction. Newborns and children up to 2 y.o. have little measurable serum amylase. In the early years of life, most of this enzyme is produced by the salivary glands. Amylase can be separated into pancreatic (P₁, P₂, P₃) and salivary (S₁, S₂, S₃) isoenzymes. Isoenzyme patterns are useful in identifying the organ source. Cyst fluid amylase levels with isoenzyme analysis is useful in differentiating pancreatic neoplasms (low enzyme concentration) and pseudocysts (high enzyme concentration).

**INDICATIONS:**

- Assist in the diagnosis of early acute pancreatitis; serum amylase begins to rise within 6 to 24 hr after onset and returns to normal in 2 to 7 days
- Assist in the diagnosis of macroamylasemia, a disorder seen in alcoholism, malabsorption syndrome, and other digestive problems
- Assist in the diagnosis of pancreatic duct obstruction, which causes serum amylase levels to remain elevated

**RELATED MONOGRAPHS:**

- Related tests include α₁-fetoprotein, blood groups and antibodies, chromosome analysis, fetal fibronectin, Kleihauer-Betke test, L/S ratio, lupus anticoagulant antibodies, and US biophysical profile obstetric.
- Refer to the Reproductive System table at the end of the book for related tests by body system.

Access additional resources at davisplus.fadavis.com
• Detect blunt trauma or inadvertent surgical trauma to the pancreas
• Differentiate between acute pancreatitis and other causes of abdominal pain that require surgery

RESULT:

Increased in:

• Amylase is released from any damaged cell in which it is stored so conditions that affect the pancreas and parotid glands and cause cellular destruction demonstrate elevated amylase levels.
• Abdominal trauma
• Alcoholism (salivary origin most likely)
• Carcinoma of the head of the pancreas (advanced)
• Common bile duct obstruction (accumulation in blood due to impaired pancreatic duct flow)
• Diabetic ketoacidosis (salivary origin)
• Duodenal obstruction (accumulation in blood due to leakage from the gut)
• Ectopic pregnancy (ectopic enzyme production by the fallopian tubes)
• Gastric resection (accumulation in blood due to leakage from the gut)
• Macroamylasemia (accumulation in blood due to inability of renal glomeruli to filter large molecules)
• Mumps (salivary origin)
• Pancreatic cyst and pseudocyst
• Pancreatitis
• Parotitis
• Perforated peptic ulcer involving the pancreas
• Peritonitis (accumulation in blood due to leakage from the gut)
• Postoperative period
• Renal disease (accumulation in blood due to lack of kidney excretion)

• Some tumors of the lung and ovaries (ectopic enzyme production)

Decreased in:

• Hepatic disease (severe) (may be due to lack of amino acid production necessary for enzyme manufacture)
• Pancreatectomy
• Pancreatic insufficiency

CRITICAL VALUES: N/A

INTERFERING FACTORS:

• Drugs and substances that may increase amylase levels include aminosalicylic acid, amoxapine, azathioprine, bethanecol, calcitrol, cholinergics, chlorthalidone, cisplatin, cinetidine, clozapine, codeine, corticosteroids, diazoxide, felbamate, fentanyl, fluvastatin, glucocorticoids, hydantoin derivatives, hydrochlorothiazide, hydroflumethiazide, isoniazid, meperidine, mirtazapine, morphine, nitrofurantoin, pegasparagase, penicillamine, pentazocine, phenylbutazone, potassium iodide, procyclidine, tetracycline, thiazide diuretics, valproic acid, zalcitabine, and zidovudine.
• Drugs that may decrease amylase levels include anabolic steroids, citrates, and fluorides.

PRETEST:

• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is primarily used to assess pancreatic function.
AMYLASE

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Nutritional considerations: Increased amylase levels may be associated with gastrointestinal disease or alcoholism. Small, frequent meals work best for patients with gastrointestinal disorders. Consideration should be given to dietary alterations in the case of gastrointestinal disorders. Usually after acute symptoms subside and bowel sounds return, patients are given a clear liquid diet, progressing to a low-fat, high-carbohydrate diet. Vitamin B<sub>12</sub> may be ordered for parenteral administration to patients with decreased levels, especially if their disease prevents adequate absorption of the vitamin. The alcoholic patient should be encouraged to avoid alcohol and to seek appropriate counseling for substance abuse.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include ALT, ALP, AST, bilirubin, cancer antigens, calcium, C-Peptide, CT pancreas, ERCP, fecal fat, GGT, lipase, magnesium, MRI pancreas, mumps serology, peritoneal fluid analysis, triglycerides, US pancreas, and complete blood count, WBC count and differential.

See the Endocrine, Gastrointestinal, and Hepatobiliary System tables at the back of the book for related tests by body system.
**Analgesic and Antipyretic Drugs:**

**Acetaminophen, Acetylsalicylic Acid**

**SYNONYM/ACRONYM:** Acetaminophen (Acephen, Apacet, Aspirin Free Anacin, Banesin, Dapa, Datril, Dorcol, Gebapap, Halenol, Liquiprin, Meda Cap, Panadol, Redutemp, Tempra, Tylenol, Ty-Pap, Uni-Ace); Acetylsalicylic acid (salicylate, aspirin, Anacin, Aspergum, Bufferin, Ecotrin, Empirin, Measurin, Synalgos, ZORprin, ASA).

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Immunoassay)

*Conventional units.

**DESCRIPTION:** Acetaminophen is used for headache, fever, and pain relief, especially for individuals unable to take salicylate products or who have bleeding conditions. It is the analgesic of choice for children less than 13 y.o.; salicylates are avoided in this age group because of the association between aspirin and Reye’s syndrome. Acetaminophen is rapidly absorbed from the gastrointestinal tract and reaches peak concentration within 30 to 60 min after administration of a therapeutic dose. It can be a silent killer because, by the time symptoms of intoxication appear 24 to 48 hr after ingestion, the antidote is ineffective. Acetylsalicylic acid (ASA) is also used for headache, fever, and pain relief. Some patients with cardiovascular disease take small prophylactic doses. The main site of toxicity for both drugs is the liver, particularly in the presence of liver disease or decreased drug metabolism and excretion.

Many factors must be considered in interpreting drug levels, including patient age, patient weight, interacting medications, electrolyte balance, protein levels, water balance, conditions that affect absorption and excretion, and foods, herbals, vitamins, and minerals that can potentiate or inhibit the intended target concentration.
INDICATIONS:
• Suspected overdose
• Suspected toxicity
• Therapeutic monitoring

RESULT:
Increased in:
• Acetaminophen
  Alcoholic cirrhosis (blood level increases due to inability of damaged liver to metabolize the drug)
  Liver disease (blood level increases due to inability of damaged liver to metabolize the drug)
  Toxicity
• ASA
  Toxicity

Decreased in:
• Noncompliance with therapeutic regimen

CRITICAL VALUES:
Note: The adverse effects of subtherapeutic levels are also important. Care should be taken to investigate signs and symptoms of too little and too much medication. Note and immediately report to the health care practitioner (HCP) any critically increased values and related symptoms.

Acetaminophen: Greater Than 150 mcg/mL (4 Hours Postingestion); Greater Than 50 mcg/mL (12 Hours Postingestion)
Signs and symptoms of acetaminophen intoxication occur in stages over a period of time. In stage I (0 to 24 hr after ingestion), symptoms may include gastrointestinal irritation, pallor, lethargy, diaphoresis, metabolic acidosis, and possibly coma. In stage II (24 to 48 hr after ingestion), signs and symptoms may include right upper quadrant abdominal pain; elevated liver enzymes, aspartate aminotransferase (AST), and alanine aminotransferase (ALT); and possible decreased renal function. In stage III (72 to 96 hr after ingestion), signs and symptoms may include nausea, vomiting, jaundice, confusion, coagulation disorders, continued elevation of AST and ALT, decreased renal function, and coma. Intervention may include gastrointestinal decontamination (stomach pumping) if the patient presents within 6 hr of ingestion or administration of N-acetylcysteine (Mucomyst) in the case of an acute intoxication in which the patient presents more than 6 hr after ingestion. (See figure below.)

ASA: Greater Than 50 mg/dL
Signs and symptoms of salicylate intoxication include ketosis, convulsions, dizziness, nausea, vomiting, hyperactivity, hyperglycemia, hyperpnea, hyperthermia, respiratory arrest, and tinnitus. Possible interventions
include administration of activated charcoal as vomiting ceases, alkalization of the urine with bicarbonate, and a single dose of vitamin K (for rare instances of hypoprothrombinaemia). (See figure below.)

**Acetaminophen Toxicity Nomogram**

**INTERFERING FACTORS:**
- Blood drawn in serum separator tubes (gel tubes).
- Contraindicated in patients with liver disease, and caution advised in patients with renal impairment.
- Drugs that may increase acetaminophen levels include diflunisal, metoclopramide, and probenecid.
- Drugs that may decrease acetaminophen levels include carbamazepine, cholestyramine, iron, oral contraceptives, and propantheline.
- Drugs that increase ASA levels include choline magnesium trisalicylate, cimetidine, furosemide, and sulfipyrazone.
- Drugs and substances that decrease ASA levels include activated charcoal, antacids (aluminum hydroxide), corticosteroids, and iron.

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to monitor therapeutic levels and detect toxic levels of acetaminophen and salicylate.
- Obtain a complete history of the time and amount of drug ingested by the patient.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Review results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the
patient to breathe normally and to avoid unnecessary movement.

observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection, noting the last dose of medication taken. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop the bleeding. Observe the venipuncture site for bleeding and hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

Post-test:
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- **Nutritional considerations** include the avoidance of alcohol consumption.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Explain to the patient the importance of following the medication regimen and instructions regarding food and drug interactions. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient to be prepared to provide the pharmacist with a list of other medications he or she is already taking in the event that the requesting HCP prescribes a medication.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

Related Monographs:
- Related tests include ALT, AST, bilirubin, biopsy liver, BUN, complete blood count, creatinine, electrolytes, glucose, lactic acid, aPTT, and PT/INR.
- See the Genitourinary and Hepatobiliary System tables in the back of the book for related tests by body system.

**Angiography, Abdomen**

**Syonym/Acronym:** Abdominal angiogram, abdominal arteriography

**Area of Application:** Abdomen.

**Contrast:** Intravenous iodine based.

**Description:** Angiography allows x-ray visualization of the large and small arteries, veins, and associated branches of the abdominal vasculature and organ parenchyma after contrast medium injection. This visualization is accomplished by the injection of contrast medium through a catheter, which most commonly
has been inserted into the femoral artery and advanced through the iliac artery and aorta into the organ-specific artery. Images of the organ under study and associated vessels are displayed on a monitor and recorded or stored electronically for future viewing and evaluation. Patterns of circulation, organ function, and changes in vessel wall appearance can be viewed to help diagnose the presence of vascular abnormalities, aneurysm, tumor, trauma, or lesions. The catheter used to administer the contrast medium to confirm the diagnosis of organ lesions may be used to deliver chemotherapeutic drugs or different types of materials used to stop bleeding. Catheters with attached inflatable balloons and wire mesh stents are used to widen areas of stenosis and to keep vessels open, frequently replacing surgery. Angiography is one of the definitive tests for organ disease and may be used to evaluate chronic disease and organ failure, treat arterial stenosis, differentiate a vascular cyst from hypervascular cancers, and evaluate the effectiveness of medical or surgical treatment.

INDICATIONS:
- Aid in angioplasty, atherectomy, or stent placement
- Allow infusion of thrombolytic drugs into an occluded artery
- Detect arterial occlusion, which may be evidenced by a transection of the artery caused by trauma or penetrating injury
- Detect artery stenosis, evidenced by vessel dilation, collateral vessels, or increased vascular pressure

RESULT:
Normal findings in:
- Normal structure, function, and patency of abdominal organ vessels
- Contrast medium normally circulates throughout abdomen symmetrically and without interruption
- No evidence of obstruction, variations in number and size of vessels, malformations, cysts, or tumors

Abnormal findings in:
- Abscess or inflammation
- Arterial aneurysm
- Arterial stenosis, dysplasia, or organ infarction
- Arteriovenous fistula or other abnormalities
- Congenital anomalies
- Cysts or tumors
- Trauma causing tears or other disruption

CRITICAL VALUES:
- Abcess
- Aneurysm

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.
INTERFERING FACTORS:

This procedure is contraindicated for:

- Patients with allergies to shellfish or iodinated contrast medium. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to contrast medium may benefit from pre-medication with corticosteroids or the use of nonionic contrast medium.
- Patients with bleeding disorders.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risk of radiation exposure to the fetus.
- Elderly and compromised patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.

Factors that may impair clear imaging:

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:

- Consultation with a HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses cardiovascular function.
- Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, or anesthetics.
- Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed since contrast medium is to be used.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium. Ensure that barium studies were performed more than 4 days before angiography.
- Record the date of the last menstrual period and determine the possibility
of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.

If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.

Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a radiology or vascular suite by a HCP and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.

Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

Instruct the patient to fast and restrict fluids for 2 to 4 hr prior to the procedure. Protocols may vary from facility to facility.

This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure the patient has complied with dietary and fluid restrictions for 2 to 4 hr prior to the procedure.
- Ensure the patient has removed all external metallic objects from the area to be examined.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs, and assess neurologic status. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish a baseline rhythm; determine if the patient has ventricular arrhythmias.
- Using a pen, mark the site of the patient’s peripheral pulses before angiography; this allows for quicker and more consistent assessment of the pulses after the procedure.
- Place the patient in the supine position on an exam table. Cleanse the
selected area, and cover with a sterile drape. A local anesthetic is injected at the site, and a small incision is made or a needle inserted under fluoroscopy. The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to examine the vessels after a time and to monitor the venous phase of the procedure. Instruct the patient to inhale deeply and hold his or her breathe while the images are taken, and then to exhale after the images are taken. Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm). The needle or catheter is removed, and a pressure dressing is applied over the puncture site.

POST-TEST: A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient. Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the HCP. Renal function should be assessed before metformin is resumed. Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Compare with baseline values. Protocols may vary from facility to facility. Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting. Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

Observe the needle insertion site for bleeding, inflammation, or hematoma formation. Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus. Instruct the patient in the care and assessment of the site and to observe for bleeding, hematoma formation, bile leakage, and inflammation. Any pleuritic pain, persistent right shoulder pain, or abdominal pain should be reported to the appropriate HCP. Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema. Instruct the patient to maintain bed rest for 4 to 6 hr after the procedure or as ordered. Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS: Related tests include angiography renal, BUN, CT abdomen, CT angiography, CT brain, CT spleen, CT thoracic, creatinine, KUB, MRA, MRI abdomen, MRI brain, MRI chest, MRI pelvis, aPTT, PT/INR, renogram, and US lower extremity. See the Cardiovascular System table at the back of the book for related tests by body system.
SYNONYM/ACRONYM: Adrenal angiogram, adrenal arteriography.

AREA OF APPLICATION: Adrenal gland.

CONTRAST: Intravenous iodine based.

DESCRIPTION: Adrenal angiography evaluates adrenal dysfunction by allowing x-ray visualization of the large and small arteries of the adrenal gland vasculature and paren-chyma. This visualization is accomplished by the injection of contrast medium through a catheter that has been inserted into the femoral artery for viewing the artery (angiography) or into the femoral vein for viewing the veins (venography). After the catheter is in place, a blood sample may be taken from the vein of each gland to assess cortisol levels in determining a diagnosis of Cushing’s syndrome or the presence of pheochromocytoma. After injection of the contrast medium through the catheter, images of the adrenal glands and associated vessels surrounding the adrenal tissue are displayed on a monitor and are recorded on film or electronically. Patterns of circulation, adrenal function, and changes in vessel wall appearance can be viewed to help diagnose the presence of vascular abnormalities, trauma, or lesions. This definitive test for adrenal disease may be used to evaluate chronic adrenal disease, evaluate arterial or venous stenosis, differentiate an adrenal cyst from adrenal tumors, and evaluate medical therapy or surgery of the adrenal glands.

INDICATIONS:
• Assist in the infusion of thrombolytic drugs into an occluded artery
• Assist with the collection of blood samples from the vein for laboratory analysis
• Detect adrenal hyperplasia
• Detect and determine the location of adrenal tumors evidenced by arterial supply, extent of venous invasion, and tumor vascularity
• Detect arterial occlusion, evidenced by a transection of the artery caused by trauma or a penetrating injury
• Detect arterial stenosis, evidenced by vessel dilation, collateral vessels, or increased vascular pressure
• Detect nonmalignant tumors before surgical resection
• Detect thrombosis, arteriovenous fistula, aneurysms, or emboli in vessels
• Differentiate between adrenal tumors and adrenal cysts
• Evaluate tumor vascularity before surgery or embolization
• Perform angioplasty, perform atherectomy, or place a stent

RESULT:

Normal findings in:
• Normal structure, function, and patency of adrenal vessels
• Contrast medium circulating throughout the adrenal gland symmetrically and without interruption
• No evidence of obstruction, variations in number and size of vessels and organs, malformations, cysts, or tumors
Abnormal findings in:
• Adrenal adenoma
• Adrenal carcinoma
• Bilateral adrenal hyperplasia
• Pheochromocytoma

Critical values: N/A

Interfering factors:
This procedure is contraindicated for:
• Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
• Patients with bleeding disorders.
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
• Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
• Patients who are in renal failure.

Factors that may impair clear imaging:
• Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
• Retained barium from a previous radiologic procedure
• Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the examination room with the patient should wear a protective lead apron or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
• Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

Nursing implications and procedure

Pretest:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses adrenal gland function.
• Obtain a history of the patient’s complaints, including a list of known allergens (especially allergies or sensitivities to latex, iodine, seafood, anesthetics or contrast medium).
• Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
• Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium. Ensure that barium studies were performed more than 4 days before angiography.
• Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Record the date of the last menstrual period and determine the possibility
Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutriceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis. Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a radiology or vascular suite by a HCP and takes approximately 30 to 60 min.

**Sensitivity to social and cultural issues**
as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused. Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

The patient should fast and restrict fluids for 2 to 4 hr prior to the procedure. Protocols may vary from facility to facility.

This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations.
- Ensure the patient has removed all external metallic objects from the area to be examined.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions.
- Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish a baseline rhythm; determine if the patient has ventricular arrhythmias.
- Using a pen, mark the site of the patient’s peripheral pulses before angiography; this allows for quicker and more consistent assessment of the pulses after the procedure.
- Place the patient in the supine position on an exam table. Cleanse
the selected area, and cover with a sterile drape.

A local anesthetic is injected at the site, and a small incision is made or a needle inserted under fluoroscopy. The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to examine the vessels after a time and to monitor the venous phase of the procedure.

Ask the patient to inhale deeply and hold his or her breathe while the x-ray images are taken, and then to exhale after the images are taken.

Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

The needle or catheter is removed, and a pressure dressing is applied over the puncture site.

Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the HCP. Renal function should be assessed before metformin is resumed.

Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Compare with baseline values. Protocols may vary from facility to facility.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

Observe the needle insertion site for bleeding, inflammation, or hematoma formation.

Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.

Instruct the patient in the care and assessment of the site and to observe for bleeding, hematoma formation, bile leakage and inflammation. Any pleuritic pain, persistent right shoulder pain, or abdominal pain should be reported to the appropriate HCP.

Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.

Instruct the patient to maintain bed rest for 4 to 6 hr after the procedure or as ordered.

Nutritional considerations: A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.

Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include adrenal gland scan, ACTH and challenge tests, catecholamines, cortisol and challenge tests, CT abdomen, creatinine, BUN, glucose tolerance tests, HVA, KUB study, MRI abdomen, metanephrines, aPTT, PT/INR, renin, and VMA.

Refer to the Endocrine System table in the back of the book for related tests by body system.
**Angiography, Carotid**

**SYNONYM/ACRONYM:** Carotid angiogram, carotid arteriography.

**AREA OF APPLICATION:** Neck/cervical area.

**CONTRAST:** Intravenous iodine based.

**DESCRIPTION:** The test evaluates blood vessels in the neck carrying arterial blood. This visualization is accomplished by the injection of contrast material through a catheter that has been inserted into the femoral artery for viewing the artery (angiography). The angiographic catheter is a long tube about the size of a strand of spaghetti. After the injection of contrast media through the catheter, x-ray images of the carotid artery and associated vessels in surrounding tissue are displayed on a monitor and are recorded on film or electronically. The x-ray equipment is mounted on a C-shaped bed with the x-ray device beneath the table on which the patient lies. Over the patient is an image intensifier that receives the x-rays after they pass through the patient. Patterns of circulation or changes in vessel wall appearance can be viewed to help diagnose the presence of vascular abnormalities, disease, narrowing, enlargement, blockage, trauma, or lesions. This definitive test for arterial disease may be used to evaluate chronic vascular disease, arterial or venous stenosis, and medical therapy or surgery of the vasculature. Catheter angiography still is used in patients who may undergo surgery, angioplasty, or stent placement.

**INDICATIONS:**
- Aid in angioplasty, atherectomy, or stent placement
- Allow infusion of thrombolytic drugs into an occluded artery
- Detect arterial occlusion, which may be evidenced by a transection of the artery caused by trauma or penetrating injury
- Detect artery stenosis, evidenced by vessel dilation, collateral vessels, or increased vascular pressure
- Detect nonmalignant tumors before surgical resection
- Detect tumors and arterial supply, extent of venous invasion, and tumor vascularity
- Detect thrombosis, arteriovenous fistula, aneurysms, or emboli in vessels
- Evaluate placement of a stent
- Differentiate between tumors and cysts
- Evaluate tumor vascularity before surgery or embolization
- Evaluate the vascular system of prospective organ donors before surgery

**RESULT:**

*Normal finding in:*
- Normal structure, function and patency of carotid arteries
- Contrast medium normally circulates throughout neck symmetrically and without interruption
- No evidence of obstruction, variations in number and size of vessels, malformations, cysts, or tumors
Abnormal findings in:
- Abscess or inflammation
- Arterial aneurysm
- Arterial stenosis or dysplasia
- Aneurysms
- Arteriovenous fistula or other abnormalities
- Congenital anomalies
- Cysts or tumors
- Trauma causing tears or other disruption
- Vascular blockage or other disruption

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients with allergies to shellfish or iodinated contrast medium. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients with bleeding disorders.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risk of radiation exposure to the fetus.
- Elderly and compromised patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.

Factors that may impair clear imaging:
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium. Ensure that barium studies were performed more than 4 days before angiography.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.

If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.

Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a radiology or vascular suite by a HCP and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.

Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

Instruct the patient to fast and restrict fluids for 2 to 4 hr prior to the procedure. Protocols may vary from facility to facility.

This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

Ensure the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations.

Ensure the patient has removed all external metallic objects from the area to be examined.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Establish an IV fluid line for the injection of emergency drugs and of sedatives.

Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish a baseline rhythm; determine if the patient has ventricular arrhythmias.

Using a pen, mark the site of the patient’s peripheral pulses before angiography; this allows for quicker
and more consistent assessment of the pulses after the procedure.

- Place the patient in the supine position on an exam table. Cleanse the selected area, and cover with a sterile drape.
- A local anesthetic is injected at the site, and a small incision is made or a needle inserted under fluoroscopy.
- The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to examine the vessels after a time and to monitor the venous phase of the procedure.
- Instruct the patient to inhale deeply and hold his or her breath while the images are taken, and then to exhale after the images are taken.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

**POST-TEST:**

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the HCP. Renal function should be assessed before metformin is resumed.
- Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Compare with baseline values. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle insertion site for bleeding, inflammation, or hematoma formation.

- Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.
- Instruct the patient in the care and assessment of the site and to observe for bleeding, hematoma formation, bile leakage, and inflammation. Any pleuritic pain, persistent right shoulder pain, or abdominal pain should be reported to the appropriate HCP.
- Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- Instruct the patient to maintain bed rest for 4 to 6 hr after the procedure or as ordered.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include angiography abdomen, BUN, CT angiography, CT brain, creatinine, blood, ECG, exercise stress test, MRA, MRI brain, PT/INR, plethysmography, US arterial doppler lower extremities, and US peripheral doppler.
- See the Cardiovascular System table at the back of the book for related tests by body system.
Angiography, Coronary

SYNONYM/ACRONYM: Angiocardiography, cardiac angiography, cardiac catheterization, cineangiocardiography, coronary arteriography.

AREA OF APPLICATION: Heart

CONTRAST: Intravenous iodine based.

DESCRIPTION: Angiography allows x-ray visualization of the heart, aorta, inferior vena cava, pulmonary artery and vein, and coronary arteries after injection of contrast medium. Contrast medium is injected through a catheter, which has been inserted into a peripheral vein for a right heart catheterization or an artery for a left heart catheterization; through the same catheter, cardiac pressures are recorded. Images of the heart and associated vessels are displayed on a monitor and are recorded on film or electronically. Patterns of circulation, cardiac output, cardiac functions, and changes in vessel wall appearance can be viewed to help diagnose the presence of vascular abnormalities or lesions. Pulmonary artery abnormalities are seen with right heart views, and coronary artery and thoracic aorta abnormalities are seen with left heart views. Coronary angiography is a definitive test for coronary artery disease, and it is useful for evaluating other types of cardiac abnormalities.

INDICATIONS:
• Allow infusion of thrombolytic drugs into an occluded coronary
• Detect narrowing of coronary vessels or abnormalities of the great vessels in patients with angina, syncope, abnormal electrocardiogram, hypercholesteremia with chest pain, and persistent chest pain after revascularization
• Evaluate cardiac muscle function
• Evaluate cardiac valvular and septal defects
• Evaluate disease associated with the aortic arch
• Evaluate previous cardiac surgery or other interventional procedures
• Evaluate ventricular aneurysms
• Monitor pulmonary pressures and cardiac output
• Perform angioplasty, perform atherectomy, or place a stent
• Quantify the severity of atherosclerotic, occlusive coronary artery disease

RESULT:
Normal findings in:
• Normal great vessels and coronary arteries

Abnormal findings in:
• Aortic atherosclerosis
• Aortic dissection
• Aortitis
• Aneurysms
• Cardiomyopathy
• Congenital anomalies
• Coronary artery atherosclerosis and degree of obstruction
• Graft occlusion
• Pulmonary artery abnormalities
• Septal defects
• Trauma causing tears or other disruption
• Tumors
• Valvular disease
CRITICAL VALUES:
• Aneurysm
• Aortic dissection

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with allergies to shellfish or iodinated contrast medium. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
• Patients with bleeding disorders.
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risk of radiation exposure to the fetus.
• Elderly and compromised patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
• Patients who are in renal failure.

Factors that may impair clear imaging:
• Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
• Retained barium from a previous radiologic procedure
• Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
• Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses cardiovascular function.
• Obtain a history of the patient's complaints, including a list of known allergens (especially allergies or sensitivities to latex, iodine, seafood, anesthetics or contrast medium).
• Obtain a history of results of the patient's cardiovascular and respiratory system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
• Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium. Ensure that barium studies were performed more than 4 days before angiography.
• Record the date of last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Access additional resources at davisplus.fadavis.com
Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.

If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non-insulin dependent (type 2) diabetes should be instructed as ordered to discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.

Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a radiology or vascular suite by a HCP and takes approximately 30–60 min.

As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include angiography carotid, blood pool imaging, BNP, BUN, chest x-ray, CT abdomen, CT angiography, CT biliary tract and liver, CT cardiac scoring, CT spleen, CT thoracic, CK, creatinine, CRP, electrocardiography, electrocardiography transesophageal, Holter monitor, homocysteine, MR angiography, MRI abdomen, MRI chest, myocardial perfusion heart scan, plethysmography, aPTT, PT/INR, troponin, and US arterial doppler carotid.

- Refer to the Cardiovascular and Respiratory System tables at the back of the book for related tests by body system.
**Angiography, Pulmonary**

**SYNONYM/ACRONYM:** Pulmonary angiography, pulmonary arteriography.

**AREA OF APPLICATION:** Pulmonary vasculature.

**CONTRAST:** Intravenous iodine based.

**DESCRIPTION:** Pulmonary angiography allows x-ray visualization of the pulmonary vasculature after injection of an iodinated contrast medium into the pulmonary artery or a branch of this great vessel. Contrast medium is injected through a catheter that has been inserted into the vascular system, usually through the femoral vein. It is one of the definitive tests for pulmonary embolism, but it is also useful for evaluating other types of pulmonary vascular abnormalities. It is definitive for peripheral pulmonary artery stenosis, anomalous pulmonary venous drainage, and pulmonary fistulae. Hemodynamic measurements during pulmonary angiography can assist in the diagnosis of pulmonary hypertension and cor pulmonale.

- Determine the cause of recurrent or severe hemoptysis
- Evaluate pulmonary circulation

**RESULT:**

**Normal findings in:**
- Normal pulmonary vasculature; radiopaque iodine contrast medium should circulate symmetrically and without interruption through the pulmonary circulatory system.

**Abnormal findings in:**
- Aneurysms
- Arterial hypoplasia or stenosis
- Arteriovenous malformations
- Bleeding caused by tuberculosis, bronchiectasis, sarcoidosis, or aspergilloma
- Inflammatory diseases
- Pulmonary embolism (PE) acute or chronic
- Pulmonary sequestration
- Tumors

**CRITICAL VALUES:**
- PE

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

**INTERFERING FACTORS:**

This procedure is contraindicated for:
- Patients with allergies to shellfish or iodinated contrast medium. The contrast medium
used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.

- Patients with bleeding disorders.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.

Factors that may impair clear imaging:
- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses cardiovascular function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, or anesthetics.
- Obtain a history of the patient’s cardiovascular and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium. Ensure that barium studies were performed more than 4 days before angiography.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.

Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a radiology or vascular suite by a HCP and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives. Usually normal saline is infused.

Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

Instruct the patient to fast and restrict fluids for 2 to 4 hr prior to the procedure. Protocols may vary from facility to facility.

This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

Ensure the patient has removed all external metallic objects from the area to be examined.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or anti-histamines before the procedure. Use nonionic contrast medium for the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

Observe standard precautions, and follow the general guidelines in Appendix A.

Establish an IV fluid line for the injection of emergency drugs and of sedatives.

Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish a baseline rhythm; determine if the patient has ventricular arrhythmias.

Using a pen, mark the site of the patients peripheral pulses before angiography; this allows for quicker and more consistent assessment of the pulses after the procedure.

Place the patient in the supine position on an exam table. Cleanse the selected area, and cover with a sterile drape.

A local anesthetic is injected at the site, and a small incision is made or a needle inserted under fluoroscopy.

The contrast medium is injected, and a rapid series of images is taken during
and after the filling of the vessels to be examined.
- Instruct the patient to inhale deeply and hold his or her breath while the images are taken, and then to exhale after the images are taken.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

**POST-TEST:**
- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the HCP. Renal function should be assessed before metformin is resumed.
- Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take the temperature every 4 hr for 24 hr. Compare with baseline values. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle insertion site for bleeding, inflammation, or hematoma formation.
- Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.
- Instruct the patient in the care and assessment of the site and to observe for bleeding, hematoma formation, bile leakage, and inflammation. Any pleuritic pain, persistent right shoulder pain, or abdominal pain should be reported to the appropriate HCP.
- Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- Instruct the patient to maintain bed rest for 4 to 6 hr after the procedure or as ordered.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include alveolar/arterial gradient, blood gases, BUN, chest x-ray, creatinine, CT angiography, CT thoracic, ECG, FDP, lactic acid, lung perfusion scan, lung ventilation scan, MRA, MRI chest, aPTT, and PT/INR.
- Refer to the Cardiovascular and Respiratory System tables at the back of the book for related tests by body system.
**ANGIOGRAPHY, RENAL**

**SYNONYM/ACRONYM:** Renal angiogram, renal arteriography.

**AREA OF APPLICATION:** Kidney.

**CONTRAST:** Intravenous iodine based.

**DESCRIPTION:** Renal angiography allows x-ray visualization of the large and small arteries of the renal vasculature and parenchyma or the renal veins and their branches. Contrast medium is injected through a catheter that has been inserted into the femoral artery or vein and advanced through the iliac artery and aorta into the renal artery or the inferior vena cava into the renal vein. Images of the kidneys and associated vessels are displayed on a monitor and recorded on film or electronically. Patterns of circulation, renal function, or changes in vessel wall appearance can be viewed to help diagnose the presence of vascular abnormalities, trauma, or lesions. This definitive test for renal disease may be used to evaluate chronic renal disease, renal failure, and renal artery stenosis; differentiate a vascular renal cyst from hypervascular renal cancers; and evaluate renal transplant donors, recipients, and the kidney after transplantation.

**INDICATIONS:**
- Aid in angioplasty, atherectomy, or stent placement
- Allow infusion of thrombolytic drugs into an occluded artery
- Assist with the collection of blood samples from renal vein for renin analysis
- Detect arterial occlusion as evidenced by a transection of the renal artery caused by trauma or a penetrating injury
- Detect nonmalignant tumors before surgical resection
- Detect renal artery stenosis as evidenced by vessel dilation, collateral vessels, or increased renovascular pressure
- Detect renal tumors as evidenced by arterial supply, extent of venous invasion, and tumor vascularity
- Detect small kidney or absence of a kidney
- Detect thrombosis, arteriovenous fistulae, aneurysms, or emboli in renal vessels
- Differentiate between renal tumors and renal cysts
- Evaluate placement of a stent
- Evaluate postoperative renal transplantation for function or organ rejection
- Evaluate renal function in chronic renal failure or end-stage renal disease or hydronephrosis
- Evaluate the renal vascular system of prospective kidney donors before surgery
- Evaluate tumor vascularity before surgery or embolization

**RESULT:**

**Normal finding in:**
- Normal structure, function, and patency of renal vessels
Contrast medium circulating throughout the kidneys symmetrically and without interruption
No evidence of obstruction, variations in number and size of vessels and organs, malformations, cysts, or tumors

Abnormal findings in:
- Abscess or inflammation
- Arterial stenosis, dysplasia, or infarction
- Arteriovenous fistula or other abnormalities
- Congenital anomalies
- Intrarenal hematoma
- Renal artery aneurysm
- Renal cysts or tumors
- Trauma causing tears or other disruption

Abnormal findings in:
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Critical values: N/A

Interfering factors:

CRITICAL VALUES: N/A

Factors that may impair clear imaging:
- Patients with allergies to shellfish or iodinated contrast medium. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients with bleeding disorders.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.

Other considerations:
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses vascular and urinary function.
Obtain a history of the patient’s complaints, including a list of known allergens (especially allergies or sensitivities to latex, iodine, seafood, anesthetics or contrast medium).

Obtain a history of the patient’s genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed since contrast medium is to be used.

Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium. Ensure that barium studies were performed more than 4 days before angiography.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.

If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.

Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a radiology or vascular suite by a HCP and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives. Usually normal saline is infused.

Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.

Instruct the patient to remove jewelry, and other metallic objects from the area to be examined.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

Ensure the patient has complied with dietary, fluid, and medication restrictions for 2 to 4 hr prior to the procedure.

Ensure the patient has removed all external metallic objects from the area to be examined.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use non-ionic contrast medium for the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions.

Instruct the patient to remain still throughout the procedure because
movement produces unreliable results.

- Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

- Observe standard precautions, and follow the general guidelines in Appendix A.

- Establish an IV fluid line for the injection of emergency drugs and of sedatives.

- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

- Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish a baseline rhythm; determine if the patient has ventricular arrhythmias.

- Using a pen, mark the site of the patient’s peripheral pulses before angiography; this allows for quicker and more consistent assessment of the pulses after the procedure.

- Place the patient in the supine position on an exam table. Cleanse the selected area, and cover with a sterile drape.

- A local anesthetic is injected at the site, and a small incision is made or a needle inserted under fluoroscopy.

- The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to examine the vessels after a time and to monitor the venous phase of the procedure.

- Instruct the patient to inhale deeply and hold his or her breath while the images are taken, and then to exhale after the images are taken.

- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.

- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.

- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

**POST-TEST:**

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

- Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed.

- Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Compare with baseline values. Protocols may vary from facility to facility.

- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

- Observe the needle insertion site for bleeding, inflammation, or hematoma formation.

- Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.

- Instruct the patient in the care and assessment of the site and to observe for bleeding, hematoma formation, bile leakage, and inflammation. Any pleuritic pain, persistent right shoulder pain, or abdominal pain should be reported to the appropriate HCP.

- Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.

- Instruct the patient to maintain bed rest for 4 to 6 hr after the procedure or as ordered.

RESULT:

Increased in:
- Bronchitis (acute and chronic)  
  *(damage to pulmonary tissue releases ACE)*
- Connective tissue disease
- Gaucher's disease
- Hansen’s disease (leprosy)
- Histoplasmosis and other fungal diseases

Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

Related tests include biopsy kidney, BUN, creatinine, CT abdomen, CT angiography, culture urine, cytology urine, KUB study, IVP, MRA, MRI abdomen, aPTT, PT/INR, renin, renogram, US kidney, and UA.

Refer to the Genitourinary System table at the back of the book for related tests by body system.
• Hyperthyroidism (untreated) (thyroid hormones are thought be involved in regulation of ACE)
• Pulmonary fibrosis (damage to pulmonary tissue releases ACE)
• Rheumatoid arthritis
• Sarcoidosis (damage to pulmonary tissue releases ACE)

Decreased in:
• Advanced pulmonary carcinoma (lack of functional cells to produce ACE)
• The period following corticosteroid therapy for sarcoidosis

Anion Gap

SYNONYM/ACRONYM: Agap.

SPECIMEN: Serum (1 mL) for electrolytes collected in a red- or tiger-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Anion gap is derived mathematically from the direct measurement of sodium, chloride, and total carbon dioxide.) There are differences between serum and plasma values for some electrolytes. The reference ranges listed are based on serum values.

<table>
<thead>
<tr>
<th>Age</th>

<td>8–16 mEq/L</td>
<td>8–16 mmol/L</td>
</tr>
</tbody>
</table>

DESCRIPTION: The anion gap is used most frequently as a clinical indicator of metabolic acidosis. The most common causes of an increased gap are lactic acidosis and ketoacidosis. The concept of estimating electrolyte disturbances in the extracellular fluid is based on the principle of electrical neutrality. The formula includes the major cation (sodium) and anions (chloride and bicarbonate) found in extracellular fluid. The anion gap is calculated as follows:

\[
anion \text{ gap} = \text{sodium} - \left( \text{chloride} + \text{HCO}_3^- \right)
\]

Because bicarbonate (\(\text{HCO}_3^-\)) is not directly measured on most chemistry analyzers, it is estimated by substitution of the total carbon dioxide (TCO2) value in the calculation. Some
Indications:
- Evaluate metabolic acidosis
- Indicate the presence of a disturbance in electrolyte balance
- Indicate the need for laboratory instrument recalibration or review of electrolyte reagent preparation and stability

Result:
Increased in:
- (Metabolic acidosis that results from the accumulation of unmeasured anionic substances like proteins, phosphorus, sulfates, ketoacids, or other organic acid waste products of metabolism)
- Dehydration (severe)
- Ketoacidosis caused by starvation, high-protein/low-carbohydrate diet, diabetes, and alcoholism
- Lactic acidosis (shock, excessive exercise, some malignancies)
- Poisoning (salicylate, methanol, ethylene glycol, or paraldehyde)
- Renal failure
- Uremia

Decreased in:
- (Conditions that result in metabolic alkalosis)
- Chronic vomiting or gastric suction (alkalosis due to net loss of acid)
- Excess alkali ingestion
- Hypergammaglobulinemia (cationic unmeasured M proteins excessively produced in multiple myeloma cause an increase in measured anions)
- Hypoalbuminemia (decreased levels of unmeasured anionic proteins relative to unchanged cation concentration)
- Hyponatremia (net loss of cations)

Significant acidosis or alkalosis can result from increased levels of unmeasured cations like ionized calcium and magnesium or unmeasured anions like proteins, phosphorus, sulfates or other organic acids, the effects of which may not be accurately reflected by the calculated anion gap.

Critical Values: N/A

Interfering Factors:
- Drugs that can increase or decrease the anion gap include those listed in the individual electrolyte (i.e., sodium, chloride, calcium, magnesium, and total carbon dioxide), total protein, lactic acid, and phosphorus monographs.
- Specimens should never be collected above an intravenous line because of the potential for dilution when the specimen and the intravenous solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is
present in the intravenous solution, falsely increasing the result.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the evaluation of electrolyte balance.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular, endocrine, gastrointestinal, genitourinary, hematopoietic, immune, and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

**Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.**
- **Observe standard precautions, and follow the general guidelines in Appendix A.** Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding and hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- **Nutritional considerations:** Specific dietary considerations are listed in the monographs on individual electrolytes (i.e., sodium, chloride, calcium, magnesium, and potassium), total protein, and phosphorus.
- **Nutritional considerations:** The anion gap can be used to indicate the presence of dehydration. Evaluate the patient for signs and symptoms of dehydration. Dehydration is a significant and common finding in geriatric patients.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.
Antiarrhythmic Drugs: Digoxin, Disopyramide, Flecainide, Lidocaine, Procainamide, Quinidine

**SYNONYM/ACRONYM:** Digoxin (Digitek, Lanoxicaps, Lanoxin); disopyramide (Norpace, Norpace CR); flecainide (flecainide acetate, Tambocor); lidocaine (Xylocaine); procainamide (Procanbid, Pronestyl, Pronestyl SR); quinidine (Quinidex Extentabs, quinidine sulfaec SR, quinidine gluconate SR).

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

*Conventional units.
**DESCRIPTION:** Cardiac glycosides are used in the prophylactic management and treatment of heart failure and ventricular and atrial arrhythmias. Because these drugs have narrow therapeutic windows, they must be monitored closely. The signs and symptoms of toxicity are often difficult to distinguish from those of cardiac disease. Patients with toxic levels may show gastrointestinal, ocular, and central nervous system effects and disturbances in potassium balance.

Many factors must be considered in effective dosing and monitoring of therapeutic drugs, including patient age, patient weight, interacting medications, electrolyte balance, protein levels, water balance, conditions that affect absorption and excretion, and the ingestion of substances (e.g., foods, herbs, vitamins, and minerals) that can either potentiate or inhibit the intended target concentration.

**Level** | **Result**
--- | ---
Normal levels | Therapeutic effect
Subtherapeutic levels | Adjust dose as indicated
Toxic levels | Adjust dose as indicated
*Digoxin* | Renal impairment, CHF*, elderly patients
*Disopyramide* | Renal impairment
*Flecainide* | Renal impairment, CHF
*Lidocaine* | Hepatic impairment, CHF
*Procainamide* | Renal impairment
*Quinidine* | Renal and hepatic impairment, CHF, elderly patients

*CHF = congestive heart failure.

**IMPORTANT NOTE:** This information must be communicated clearly and accurately to avoid misunderstanding of the dose time in relation to the collection time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause of subtherapeutic levels, toxic levels, and misleading information used in the calculation of future doses.

**INDICATIONS:**
- Assist in the diagnosis and prevention of toxicity
- Monitor compliance with therapeutic regimen
- Monitor patients who have a pacemaker, who have impaired renal or hepatic function, or who are taking interacting drugs

**RESULT:**

**CRITICAL VALUES:**
- Adverse effects of subtherapeutic levels are important. Care should be taken to investigate the signs and symptoms of too little and too much...
medication. Note and immediately report to the health care provider (HCP) any critically increased values and related symptoms.

**Digoxin: Greater Than 2.5 ng/mL**

Signs and symptoms of digoxin toxicity include arrhythmias, anorexia, hyperkalemia, nausea, vomiting, diarrhea, changes in mental status, and visual disturbances (objects appear yellow or have halos around them). Possible interventions include discontinuing the medication, continuous electrocardiographic (ECG) monitoring (prolonged P-R interval, widening QRS interval, lengthening Q-Tc interval, and atrioventricular block), transcutaneous pacing, administration of activated charcoal (if the patient has a gag reflex and central nervous system function), support and treatment of electrolyte disturbance, and administration of Digibind (digoxin immune Fab). The amount of Digibind given depends on the level of digoxin to be neutralized. Digoxin levels must be measured before the administration of Digibind. Digoxin levels should not be measured for several days after administration of Digibind in patients with normal renal function (1 wk or longer in patients with decreased renal function). Digibind cross-reacts in the digoxin assay and may provide misleading elevations or decreases in values depending on the particular assay in use by the laboratory.

**Disopyramide: Greater Than 7 mcg/mL**

Signs and symptoms of disopyramide toxicity include prolonged Q-T interval, ventricular tachycardia, hypotension, and heart failure. Possible interventions include discontinuing the medication, airway support, and ECG and blood pressure monitoring.

**Flecainide: Greater Than 1 mcg/mL**

Signs and symptoms of flecainide toxicity include exaggerated pharmacologic effects resulting in arrhythmia. Possible interventions include discontinuing the medication as well as continuous ECG, respiratory, and blood pressure monitoring.

**Lidocaine: Greater Than 6 mcg/mL**

Signs and symptoms of lidocaine toxicity include slurred speech, central nervous system depression, cardiovascular depression, convulsions, muscle twitches, and possible coma. Possible interventions include continuous ECG monitoring, airway support, seizure precautions, and hourly monitoring of temperature for hyperthermia.

**Procainamide: Greater Than 12 mcg/mL; Procainamide + N-acetyl Procainamide: Greater Than 30 mcg/mL**

The active metabolite of procainamide is N-acetyl procainamide (NAPA). Signs and symptoms of procainamide toxicity include torsade de pointes (ventricular tachycardia), nausea, vomiting, agranulocytosis, and hepatic disturbances. Possible interventions include airway protection, emesis, gastric lavage, and administration of sodium lactate.

**Quinidine: Greater Than 8 mcg/mL**

Signs and symptoms of quinidine toxicity include ataxia, nausea, vomiting, diarrhea, respiratory system depression, hypotension, syncope, anuria, arrhythmias (heart block, widening of QRS and Q-T intervals), asystole, hallucinations, paresthesia, and irritability. Possible interventions include airway support, emesis, gastric lavage, administration of activated charcoal, administration of sodium lactate, and temporary transcutaneous or transvenous pacemaker.

**INTERFERING FACTORS:**

- Blood drawn in serum separator tubes (gel tubes).
- Contraindicated in patients with liver disease, and caution

Access additional resources at davisplus.fadavis.com
advised in patients with renal impairment.

- Drugs that may increase digoxin levels or increase risk of toxicity include amiodarone, amphotericin B, diclofenac, diltiazem, erythromycin, ibuprofen, indomethacin, nifedipine, nisoldipine, propafenone, propantheline, quinidine, spironolactone, tetracycline, tiapamil, troleandomycin, and verapamil.

- Drugs that may decrease digoxin levels include albuterol, aluminum hydroxide (antacids), carbamazepine, cholestyramine, colestipol, digoxin immune Fab, hydralazine, hydroxychloroquine, iron, kaolin-pectin, magnesium hydroxide, magnesium trisilicate, metoclopramide, neomycin, nitroprusside, paroxetin, phenytoin, rifabutin, sultasalazine, and ticlopidine.

- Drugs that may increase disopyramide levels or increase risk of toxicity include amiodarone, atenolol, quinidine, ritonavir, and troleandomycin.

- Drugs that may decrease disopyramide levels include phenobarbital, phenytoin, rifabutin, and rifampin.

- Drugs that may increase flecainide levels or increase risk of toxicity include amiodarone and cimetidine.

- Drugs that may decrease flecainide levels include carbamazepine, charcoal, phenobarbital, and phenytoin.

- Drugs that may increase lidocaine levels or increase risk of toxicity include β-blockers, cimetidine, metoprolol, nadolol, propranolol, and ritonavir.

- Drugs that may decrease lidocaine levels include phenytoin.

- Drugs that may increase procainamide levels or increase risk of toxicity include amiodarone, cimetidine, quinidine, ranitidine, and trimethoprim.

- Drugs that may increase quinidine levels or increase risk of toxicity include acetazolamide, amiodarone, cimetidine, itraconazole, mibefradil, nifedipine, nisoldipine, quinidine, ranitidine, thiazide diuretics, and verapamil.

- Drugs that may decrease quinidine levels include disopyramide, kaolin-pectin, ketoconazole, nifedipine, phenobarbital, phenytoin, rifabutin, and rifampin.

- Digeritoxin cross-reacts with digoxin; results are falsely elevated if digoxin is measured when the patient is taking digitoxin.

- Digitalis-like immunoreactive substances are found in the serum of some patients who are not taking digoxin, causing false-positive results. Patients whose serum contain digitalis-like immunoreactive substances usually have a condition related to salt and fluid retention, such as renal failure, hepatic failure, low-renin hypertension, and pregnancy.

- Unexpectedly low digoxin levels may be found in patients with thyroid disease.

- Disopyramide may cause a decrease in glucose levels. It may also potentiate the anticoagulating effects of warfarin.

- Long-term administration of procainamide can cause false-positive antinuclear antibody results and development of a lupuslike syndrome in some patients.

- Quinidine may potentiate the effects of neuromuscular blocking medications and warfarin anticoagulants.

- Concomitant administration of quinidine and digoxin can rapidly raise digoxin to toxic levels. If both drugs are to be given together, the digoxin level should be measured before the first dose of quinidine and again in 4 to 6 days.
ANTIARRHYTHMIC DRUGS

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to monitor for therapeutic and toxic drug levels.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s genitourinary and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals. Note the last time and dose of medication taken.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Consider recommended collection time in relation to the dosing schedule. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection, noting the last dose of medication taken. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Nutritional considerations include the avoidance of alcohol consumption.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Explain to the patient the importance of following the medication regimen and instructions regarding drug interactions. Instruct the patient to immediately report any unusual sensations (e.g., dizziness, changes in vision, loss of appetite, nausea, vomiting, diarrhea, weakness, or irregular heartbeat) to his or her HCP. Instruct the patient not to take medicine within 1 hr of food high in fiber. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient to be prepared to provide the pharmacist with a list of other medications he or she is already taking in the event that the requesting HCP prescribes a medication.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Testing for aspirin responsiveness/resistance may be a consideration for patients, especially women, on low-dose aspirin therapy. Evaluate test results in relation to the
patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ALT, albumin, ALP, apolipoprotein A and B, atrial natriuretic peptide, BNP, blood gases, BUN, CRP, calcium, calcium ionized, cholesterol (total, HDL, and LDL), CK and isoenzymes, creatinine, glucose, glycated hemoglobin, homocystine, ketones, LDH and isoenzymes, magnesium, myoglobin, platelet count, potassium, triglycerides, and troponin.
- See the Genitourinary and Hepatobiliary System tables in the back of the book for related tests by body system.

### Antibiotic Drugs—Aminoglycosides: Amikacin, Gentamicin, Tobramycin; Tricyclic Glycopeptide: Vancomycin

**SYNONYM/ACRONYM:** Amikacin (Amikin); gentamicin (Garamycin, Genoptic, Gentacidin, Gentafair, Gentak, Gentamar, Gentrasul, G-myycin, Oco-Mycin, Spectro-Genta); tobramycin (Nebcin, Tobrex); vancomycin (Lyphocin, Vancocin, Vancoled).

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

*Conventional units.
**DESCRIPTION:** The aminoglycoside antibiotics amikacin, gentamicin, and tobramycin are used against many gram-negative (Acinetobacter, Citrobacter, Enterobacter, Escherichia coli, Klebsiella, Proteus, Providencia, Pseudomonas, Raoultella, Salmonella, Serratia, Shigella, and Stenotrophomonas) and some gram-positive (Staphylococcus aureus) pathogenic microorganisms. Aminoglycosides are poorly absorbed through the gastrointestinal tract and are most frequently administered IV.

Vancomycin is a tricyclic glycopeptide antibiotic used against many gram-positive microorganisms, such as staphylococci, Streptococcus pneumoniae, group A β-hemolytic streptococci, enterococci, Corynebacterium, and Clostridium. Vancomycin has also been used in an oral form for the treatment of pseudomembranous colitis resulting from Clostridium difficile infection. This approach is less frequently used because of the emergence of vancomycin-resistant enterococci (VRE).

Many factors must be considered in effective dosing and monitoring of therapeutic drugs, including patient age, patient weight, interacting medications, electrolyte balance, protein levels, water balance, conditions that affect absorption and excretion, and ingestion of substances (e.g., foods, herbals, vitamins, and minerals) that can either potentiate or inhibit the intended target concentration. The most serious side effects of the aminoglycosides and vancomycin are nephrotoxicity and irreversible ototoxicity (uncommon). Peak and trough collection times should be documented carefully in relation to the time of medication administration. Creatinine levels should be monitored every 2 to 3 days to detect renal impairment due to toxic drug levels.

**IMPORTANT NOTE:**
This information must be clearly and accurately communicated to avoid misunderstanding of the dose time in relation to the collection time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause of subtherapeutic levels, toxic levels, and misleading information used in the calculation of future doses. Some pharmacies use a computerized pharmacokinetics approach to dosing that eliminates the need to be concerned about peak and trough collections; random specimens are adequate.

**INDICATIONS:**
- Assist in the diagnosis and prevention of toxicity
- Monitor renal dialysis patients or patients with rapidly changing renal function
- Monitor therapeutic regimen

<td>Tobramycin</td>
<td>Renal, hearing impairment</td>
</tr>
<tr>
<td>Vancomycin</td>
<td>Renal, hearing impairment</td>
</tr>
</tbody>
</table>
**CRITICAL VALUES:** The adverse effects of subtherapeutic levels are important. Care should be taken to investigate signs and symptoms of too little and too much medication. Note and immediately report to the health care provider (HCP) any critically increased or subtherapeutic values and related symptoms.

**Drug Name** | **Toxic Levels**
--- | ---
Amikacin | Peak greater than 30 mcg/mL, trough greater than 8 mcg/mL
Gentamicin | Peak greater than 12 mcg/mL, trough greater than 2 mcg/mL
Tobramycin | Peak greater than 12 mcg/mL, trough greater than 2 mcg/mL
Vancomycin | Peak greater than 80 mcg/mL, trough greater than 20 mcg/mL

**INTERFERING FACTORS:**
- Blood drawn in serum separator tubes (gel tubes).
- Contraindicated in patients with liver disease, and caution advised in patients with renal impairment.
- Drugs that may decrease aminoglycoside efficacy include bleomycin, daunorubicin, doxorubicin, and penicillins (e.g., carbencillin, piperacillin).
- Obtain a culture before and after the first dose of aminoglycosides.
- The risks of ototoxicity and nephrotoxicity are increased by the concomitant administration of aminoglycosides.

**Access additional resources at davisplus.fadavis.com**
Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Consider recommended collection time in relation to the dosing schedule. Positively identify the patient and label the appropriate tubes with the corresponding patient demographics, date, and time of collection, noting the last dose of medication taken. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient receiving aminoglycosides to immediately report any unusual symptoms (e.g., hearing loss, decreased urinary output) to his or her HCP.
- **Nutritional considerations:** include the avoidance of alcohol consumption.
- Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Explain to the patient the importance of following the medication regimen and instructions regarding food and drug interactions. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient to be prepared to provide the pharmacist with a list of other medications he or she is already taking in the event that the requesting HCP prescribes a medication.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include albumin, BUN, creatinine, creatinine clearance, cultures bacterial (ear, eye, skin, wound, blood, stool, sputum), potassium, and UA.
- See the Genitourinary System table for related tests by body system.

**Antibodies, Anti-Cyclic Citrullinated Peptide**

**SYNONYM/ACRONYM:** anti-CCP antibodies.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** IgG Ab (Method: Immunoassay, Enzyme Linked Immunosorbent Assay [ELISA])
ABSTRACT:

Rheumatoid arthritis (RA) is a chronic, systemic autoimmune disease that damages the joints. Inflammation caused by autoimmune responses can affect other organs and body systems. The current American Academy of Rheumatology criteria state that a patient must have four of seven criteria to be diagnosed with RA: morning stiffness, arthritis of three or more joint areas, arthritis of hand joints, symmetric arthritis, rheumatoid nodules, abnormal amounts of rheumatoid factor, and radiographic changes. The study of RA is complex and it is believed that multiple genes may be involved in the manifestation of RA. Scientific research has revealed an unusual peptide conversion from arginine to citrulline that results in formation of antibodies whose presence provides the basis for this test. Studies show that detection of antibodies formed against citrullinated peptides is specific and sensitive in detecting RA in both early and established disease. Anti-CCP assays have 96% specificity and 78% sensitivity for RA, vs the traditional IgM Rheumatoid Factor (RF) marker with a specificity of 60% to 80% and sensitivity of 75% to 80% for RA. Anti-CCP antibodies are being used as a marker for erosive disease in RA and the antibodies have been detected in healthy patients years before the onset of RA symptoms and diagnosed disease. Some studies have shown that as many as 40% of patients seronegative for RF are anti-CCP positive. The combined presence of RF and anti-CCP has a 99.5% specificity for RA. Women are two to three times more likely to develop RA than men. While RA is most likely to affect people aged 35–50, it can affect all ages.

DESCRIPTION:

Rheumatoid arthritis (RA) is a chronic, systemic autoimmune disease that damages the joints. Inflammation caused by autoimmune responses can affect other organs and body systems. The current American Academy of Rheumatology criteria state that a patient must have four of seven criteria to be diagnosed with RA: morning stiffness, arthritis of three or more joint areas, arthritis of hand joints, symmetric arthritis, rheumatoid nodules, abnormal amounts of rheumatoid factor, and radiographic changes. The study of RA is complex and it is believed that multiple genes may be involved in the manifestation of RA. Scientific research has revealed an unusual peptide conversion from arginine to citrulline that results in formation of antibodies whose presence provides the basis for this test. Studies show that detection of antibodies formed against citrullinated peptides is specific and sensitive in detecting RA in both early and established disease. Anti-CCP assays have 96% specificity and 78% sensitivity for RA, vs the traditional IgM Rheumatoid Factor (RF) marker with a specificity of 60% to 80% and sensitivity of 75% to 80% for RA. Anti-CCP antibodies are being used as a marker for erosive disease in RA and the antibodies have been detected in healthy patients years before the onset of RA symptoms and diagnosed disease. Some studies have shown that as many as 40% of patients seronegative for RF are anti-CCP positive. The combined presence of RF and anti-CCP has a 99.5% specificity for RA. Women are two to three times more likely to develop RA than men. While RA is most likely to affect people aged 35–50, it can affect all ages.

INDICATIONS:

• Assist in the diagnosis of RA in both symptomatic and asymptomatic individuals
• Assist in the identification of erosive disease in RA
• Assist in the diagnostic prediction of RA development in undifferentiated arthritis

RESULT:

Increased in:

• RA (The immune system produces antibodies that attack the joint tissues. Inflammation of the synovium, or membrane that lines the joint, begins a process called synovitis. If untreated the synovitis can expand beyond the joint tissue to surrounding ligaments, tissues, nerves, and blood vessels.)

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

PRETEST:

• Explain to the patient that the test is primarily used to assist in the diagnosis of unexplained joint inflammation, especially when RF test results are negative.
POST-TEST:

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to anticipated chronic pain resulting from joint inflammation, impairment in mobility, muscular deformity, and perceived loss of independence. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results as appropriate. Explain the importance of physical activity in the treatment plan. Educate the patient regarding access to physical therapy, occupational therapy, and counseling services. Provide contact information, if desired, for the Arthritis Foundation (www.arthritis.org). Encourage the patient to take medications as ordered. Treatment with disease-modifying antirheumatic drugs (DMARDs) and biologic response modifiers may take as long as 2 to 3 mo to demonstrate their effects.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy.

RELATED MONOGRAPHS:

- Related laboratory tests include ANA, arthroscopy, BMD, bone scan, CRP, ESR, MRI musculoskeletal, radiography bone, RF, synovial fluid analysis, and uric acid.
- Refer to the Immune and Musculoskeletal System tables at the back of the book for related tests by body system.
**Antibodies, Anti–Glomerular Basement Membrane**

**SYNONYM/ACRONYM:** Goodpasture’s antibody, anti-GBM.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Lung or kidney tissue also may be submitted for testing. Refer to related biopsy monographs for specimen collection instructions.

**REFERENCE VALUE:** (Method: Direct or indirect immunofluorescence) Negative.

**DESCRIPTION:** Goodpasture’s syndrome is a rare hypersensitivity condition characterized by the presence of circulating anti–glomerular basement membrane antibodies in the blood and the deposition of immunoglobulin and complement in renal basement membrane tissue. Severe and progressive glomerulonephritis can result from the presence of antibodies to renal glomerular basement membrane (GBM). Autoantibodies may also be directed to act against lung tissue in Goodpasture’s syndrome.

**INDICATIONS:**
- Differentiate glomerulonephritis caused by anti-GBM from glomerulonephritis from other causes

**RESULT:**

**Increased in:**
- Glomerulonephritis
- Goodpasture’s syndrome (*nephritis of autoimmune origin*)
- Idiopathic pulmonary hemosiderosis

**Decreased in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:** N/A

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in detection and monitoring of glomerular basement membrane antibodies present in Goodpasture’s syndrome.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s genitourinary, immune, and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ANCA, biopsy kidney, biopsy lung, IVP, renogram, US kidney, and UA.
- See the Genitourinary, Immune, and Respiratory System tables at the back of the book for related tests by body system.

---

**Antibodies, Antimitochondrial and Antismooth Muscle**

**SYNONYM/ACRONYM:** AMA, ASMA.

**SPECIMAN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Indirect fluorescent antibody)
- AMA Negative or titer less than 1:20.
- ASMA Negative.
DESCRIPTION: Antimitochondrial antibodies are found in 90% of patients with primary biliary cirrhosis (PBC). PBC is identified most frequently in women aged 35 to 60. Testing is useful in the differential diagnosis of chronic liver disease as antimitochondrial antibodies are rarely detected in extrahepatic biliary obstruction, various forms of hepatitis, and cirrhosis. Antismooth muscle antibodies are autoantibodies found in high titers in the sera of patients with autoimmune diseases of the liver and bile duct. Simultaneous testing for antimitochondrial antibodies can be useful in the differential diagnosis of chronic liver disease.

INDICATIONS:
• AMA
• Assist in the diagnosis of PBC
• Assist in the differential diagnosis of chronic liver disease
• ASMA
• Differential diagnosis of liver disease

RESULT:

Increased in:
• AMA
• Hepatitis (alcoholic, viral)
• PBC
• Rheumatoid arthritis (occasionally)
• Systemic lupus erythematosus (occasionally)
• Thyroid disease (occasionally)
• ASMA
• Autoimmune hepatitis
• Chronic active viral hepatitis
• Infectious mononucleosis

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used in the differential diagnosis of chronic liver disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hepatobiliary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

**Nutritional considerations:** The presence of antimitochondrial or antismooth muscle antibodies may be associated with liver disease. Dietary recommendations may be indicated and vary depending on the severity of the condition. A low-protein diet may be in order if the liver cannot process the end products of protein metabolism. A diet of soft foods may be required if esophageal varices have developed. Ammonia levels may be used to determine whether protein should be added to or reduced from the diet. Patients should be encouraged to eat simple carbohydrates and emulsified fats (as in homogenized milk or eggs), as opposed to complex carbohydrates (e.g., starch, fiber, and glycogen [animal carbohydrates]) and complex fats, which require additional bile to emulsify them so that they can be used. Observe the cirrhotic patient carefully for the development of ascites; if ascites develops, pay strict attention to fluid and electrolyte balance.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include albumin, ALP, ammonia, ANCA, ANA, bilirubin, biopsy liver, electrolytes, and GGT.
- See the Hepatobiliary and Immune System tables at the back of the book for related tests by body system.

---

**Antibodies, Antineutrophilic Cytoplasmic**

**SYNONYM/ACRONYM:** Cytoplasmic antineutrophil cytoplasmic antibody (c-ANCA), perinuclear antineutrophil cytoplasmic antibody (p-ANCA).

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Indirect immunofluorescence) Negative.

**DESCRIPTION:** There are two types of cytoplasmic neutrophil antibodies (ANCA), identified by their cellular staining characteristics. c-ANCA (cytoplasmic) is specific for proteinase 3 in neutrophils and monocytes and is found in the sera of patients with Wegener’s granulomatosis. Wegener’s syndrome includes granulomatous inflammation of the upper and lower respiratory tract and vasculitis. p-ANCA (perinuclear) is specific for myeloperoxidase, elastase, and lactoferrin, as well as other
enzymes in neutrophils. p-ANCA is present in the sera of patients with pauci-immune necrotizing glomerulonephritis.

**INDICATIONS:**
- Assist in the diagnosis of Wegener’s granulomatosis and its variants
- Differential diagnosis of ulcerative colitis
- Distinguish between biliary cirrhosis and sclerosing cholangitis
- Distinguish between vasculitic disease and the effects of therapy

**RESULT:**

**Increased in:**
- The exact mechanism by which ANCA are developed is unknown. One theory suggests colonization with bacteria capable of expressing microbial superantigens. It is thought that the superantigens may stimulate a strong cellular autoimmune response in genetically susceptible individuals. Another theory suggests the immune system may be stimulated by an accumulation of the antigenic targets of ANCA due to ineffective destruction of old neutrophils or ineffective removal of neutrophil cell fragments containing proteinase, myeloperoxidase, elastase, lactoferrin, or other proteins.
- c-ANCA
  - Wegener’s granulomatosis and its variants
- p-ANCA
  - Alveolar hemorrhage
  - Angiitis and polyangiitis
  - Autoimmune liver disease
  - Capillaritis

**Decreased in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:** N/A

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis and monitoring of inflammatory activity in primary systemic small vessel vasculitides.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s gastrointestinal, genitourinary, hepatobiliary, immune, and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATRTEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure the gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include antibodies, anti-glomerular basement membrane, AMA/ASMA, ANA, biopsy kidney, eosinophil count, and RF.

See the Gastrointestinal, Genitourinary, Hepatobiliary, Immune, and Musculoskeletal System tables at the back of the book for related tests by body system.

**Antibodies, Antinuclear, Anti-DNA, Anticentromere, Antiextractable Nuclear Antigen, and Antiscleroderma**

**SYNONYM/ACRONYM:** Antinuclear antibodies (ANA), anti-DNA (anti-ds DNA), antiextractable nuclear antigens (anti-ENA, ribonucleoprotein [RNP], Smith [Sm], SS-A/Ro, SS-B/La), anti-Jo (antihistidyl transfer RNA [tRNA] synthase), and antiscleroderma (progressive systemic sclerosis [PSS] antibody, Scl-70 antibody, topoisomerase I antibody).

**SPECIMEN:** Serum (3 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Indirect fluorescent antibody for ANA and anticentromere; enzyme-linked immunosorbent assay [ELISA] for anti-DNA; immunodiffusion for ENA and Scl-70)

ANA and anticentromere: titer of 1:40 or less. Anti-ENA and anti-Scl-70: Negative.
Antinuclear antibodies (ANA) are autoantibodies mainly located in the nucleus of affected cells. The presence of ANA indicates systemic lupus erythematosus (SLE), related collagen vascular diseases, and immune complex diseases. Antibodies against cellular DNA are strongly associated with SLE. Anticentromere antibodies are a subset of ANA. Their presence is strongly associated with CREST syndrome (calcinosis, Raynaud’s phenomenon, esophageal dysfunction, sclerodactyly, and telangiectasia). Women are much more likely than men to be diagnosed with SLE. The extractable nuclear antigens (ENAs) include ribonucleoprotein (RNP), Smith (Sm), SS-A/ Ro, and SS-B/ La antigens. ENAs and antibodies to them are found in various combinations in individuals with combinations of overlapping rheumatologic symptoms. The American College of Rheumatology issued a list of 11 signs and/or symptoms in 1982 to assist in differentiating lupus from other similar diseases. The patient should have four or more of these to establish suspicion of lupus; the symptoms do not have to manifest at the same time: malar rash (rash over the cheeks), discoid rash (red raised patches), photosensitivity (exposure resulting in development of or increase in skin rash), oral ulcers, nonerosive arthritis involving two or more peripheral joints, pleuritis or pericarditis, renal disorder (as evidenced by excessive protein in urine or the presence of casts in the urine), neurologic disorder (seizures or psychosis in the absence of drugs known to cause these effects), hematologic disorder (hemolytic anemia, leukopenia, lymphopenia, thrombocytope- nia where the leukopenia or lymphopenia occurs on more than two occasions and the thrombocytope- nia occurs in the absence of drugs known to cause it), positive ANA in the absence of a drug known to induce lupus, or immunologic disorder (evidenced by positive anti-ds DNA, positive anti-Sm, positive antiphospholipid such as anticardiolipin antibody or a false-positive VDRL syphilis test).

**INDICATIONS:**
- Assist in the diagnosis and evaluation of SLE
- Assist in the diagnosis and evaluation of suspected immune disorders, such as rheumatoid arthritis, systemic sclerosis, polymyositis, Raynaud’s syndrome, scleroderma, Sjögren’s syndrome, and mixed connective tissue disease
- Assist in the diagnosis and evaluation of idiopathic inflammatory myopathies

**DESCRIPTION:** Antinuclear antibodies (ANA) are autoantibodies mainly located in the nucleus of affected cells. The presence of ANA indicates systemic lupus erythematosus (SLE), related collagen vascular diseases, and immune complex diseases. Antibodies against cellular DNA are strongly associated with SLE. Anticentromere antibodies are a subset of ANA. Their presence is strongly associated with CREST syndrome (calcinosis, Raynaud’s phenomenon, esophageal dysfunction, sclerodactyly, and telangiectasia). Women are much more likely than men to be diagnosed with SLE. The extractable nuclear antigens (ENAs) include ribonucleoprotein (RNP), Smith (Sm), SS-A/ Ro, and SS-B/ La antigens. ENAs and antibodies to them are found in various combinations in individuals with combinations of overlapping rheumatologic symptoms. The American College of Rheumatology issued a list of 11 signs and/or symptoms in 1982 to assist in differentiating lupus from other similar diseases. The patient should have four or more of these to establish suspicion of lupus; the symptoms do not have to manifest at the same time: malar rash (rash over the cheeks), discoid rash (red raised patches), photosensitivity (exposure resulting in development of or increase in skin rash), oral ulcers, nonerosive arthritis involving two or more peripheral joints, pleuritis or pericarditis, renal disorder (as evidenced by excessive protein in urine or the presence of casts in the urine), neurologic disorder (seizures or psychosis in the absence of drugs known to cause these effects), hematologic disorder (hemolytic anemia, leukopenia, lymphopenia, thrombocytope- nia where the leukopenia or lymphopenia occurs on more than two occasions and the thrombocytope- nia occurs in the absence of drugs known to cause it), positive ANA in the absence of a drug known to induce lupus, or immunologic disorder (evidenced by positive anti-ds DNA, positive anti-Sm, positive antiphospholipid such as anticardiolipin antibody or a false-positive VDRL syphilis test).

*ANA patterns are helpful in that certain conditions are frequently associated with specific patterns. RNP = ribonucleoprotein.

**Increased in:**
- Anti-Jo-1 is associated with dermatomyositis, idiopathic inflammatory myopathies, and polymyositis
- Anti-Jo-1 is associated with drug-induced lupus erythematosus
- ANA is associated with lupoid hepatitis
- ANA is associated with mixed connective tissue disease
- ANA is associated with polymyositis
- ANA is associated with progressive systemic sclerosis
- ANA is associated with Raynaud’s syndrome
- ANA is associated with rheumatoid arthritis
- ANA is associated with Sjögren’s syndrome
- ANA and anti-DNA are associated with SLE
- Anti-RNP is associated with mixed connective tissue disease
- Anti-Scl 70 is associated with progressive systemic sclerosis and scleroderma
- Anti-SS-A and anti-SS-B are helpful in antinuclear antibody (ANA)–negative cases of SLE
- Anti-SS-A/ANA–positive, anti-SS-B–negative patients are likely to have nephritis
- Anti-SS-A/anti-SS-B–positive sera are found in patients with neonatal lupus
- Anti-SS-A–positive patients may also have antibodies associated with antiphospholipid syndrome
- Anti-SS-A/La is associated with primary Sjögren’s syndrome
- Anti-SS-A/Ro is a predictor of congenital heart block in neonates born to mothers with SLE
- Anti-SS-A/Ro–positive patients have photosensitivity

**Decreased in:** N/A

**CRITICAL VALUES:** N/A
ANTIBODIES, ANTINUCLEAR, ANTI-DNA, ANTICENTROMERE

INTERFERING FACTORS:
- Drugs that may cause positive ANA results include carbamazepine, chlorpromazine, ethosuximide, hydralazine, isoniazid, mephenytoin, methyldopa, penicillins, phenytoin, primidone, procainamide, and quinidine.
- A patient can have lupus and test ANA-negative.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status may interfere with the test results.

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to detect the presence of antibodies associated with autoimmune disorders such as systemic lupus erythematosus and mixed connective tissue disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

INRATTEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Collagen and connective tissue diseases are chronic and, as such, they must be addressed on a continuous basis. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Provide contact information, if desired, for the Lupus Foundation of America (http://www.lupus.org).
- Educate the patient, as appropriate, regarding the importance of preventing infection, which is a significant cause of death in immunosuppressed individuals.

There are no food, fluid, or medication restrictions unless by medical direction.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include antibodies, anticyclic citrullinated peptide, arthroscopy, biopsy kidney, biopsy skin, BMD, bone scan, chest x-ray, complement C3 and C4, complement total, CRP, ESR, EMG, MRI musculoskeletal, procainamide, radiography bone, RF, and synovial fluid analysis.
- See the Immune and Musculoskeletal System tables in the back of the book for related tests by body system.

### Antibodies, Antisperm

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Immunoassay)

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**DESCRIPTION:** Normally sperm develop in the seminiferous tubules of the testes separated from circulating blood by the blood-testes barrier. Any situation that disrupts this barrier can expose sperm to detection by immune response cells in the blood and subsequent antibody formation against the sperm.

Antisperm antibodies attach to the head, midpiece, or tail of the sperm, impairing motility and ability to penetrate the cervical mucosa. The antibodies can also cause clumping of sperm, which may be noted on a semen analysis. A major cause of infertility in men is blocked efferent testicular ducts. Reabsorption of sperm from the blocked ducts may also result in development of sperm antibodies. Another more specific and sophisticated method than measurement of circulating antibodies is the immunobead sperm antibody test used to identify antibodies directly attached to the sperm. Semen and cervical mucus can also be tested for antisperm antibodies.
**INDICATIONS:**
- Evaluation of infertility

**RESULT:**

**Increased in:**
- Conditions that affect the integrity of the blood-testes barrier can result in antibody formation.
- Blocked testicular efferent duct
- Congenital absence of the vas deferens
- Cryptorchidism
- Infection (orchitis, prostatitis)
- Inguinal hernia repair prior to puberty
- Testicular biopsy
- Testicular cancer
- Testicular torsion
- Varicocele
- Vasectomy reversal

**Decreased in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- The patient should not ejaculate for 3 to 4 days before specimen collection if semen will be evaluated.
- Sperm antibodies have been detected in pregnant women and in women with primary infertility.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used in the evaluation of infertility and guidance through assisted reproductive techniques.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min and that additional specimens may be required. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider.
Antibodies, Antistreptolysin O

SYNONYM/ACRONYM: Streptozyme, ASO.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Nephelometry) Less than 200 international units/mL.

DESCRIPTION: Group A β-hemolytic streptococci secrete the enzyme streptolysin O, which can destroy red blood cells. The enzyme acts as an antigen and stimulates the immune system to develop streptolysin O antibodies. These antistreptolysin O (ASO) antibodies occur within 1 mo after the onset of a streptococcal infection. Detection of the antibody over several weeks strongly suggests exposure to group A β-hemolytic streptococci.

INDICATIONS:
- Assist in establishing a diagnosis of streptococcal infection
- Evaluate patients with streptococcal infections for the development of acute rheumatic fever or nephritis
- Monitor response to therapy in streptococcal illnesses

RESULT:

Increased in:
- Presence of antibodies, especially a rise in titer, is indicative of exposure
- Endocarditis
- Glomerulonephritis

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELEATED MONOGRAPHS:
- Related tests include HCG, LH, progesterone, semen analysis, testosterone, and US scrotal.
- See the Immune and Reproductive System tables at the back of the book for related tests by body system.
• Rheumatic fever
• Scarlet fever

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may decrease ASO titers include antibiotics and corticosteroids, because therapy suppresses antibody response.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➧ Inform the patient that the test is used to document exposure to group A streptococci bacteria.
➧ Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
➧ Obtain a history of the patient’s immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
➧ Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
➧ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
➧ Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
➧ There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:
➧ If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

➧ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
➧ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
➧ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
➧ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
➧ A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
➧ Administer antibiotics as ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy even if signs and symptoms disappear before completion of therapy.
➧ Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
➧ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
➧ Related tests include culture throat, group A streptococcal screen, and streptococcal anti-DNAse B.
➧ See the Cardiovascular, Genitourinary, and Immune System tables in the back of the book for related tests by body system.
SYNONYM/ACRONYM: Thyroid antibodies, antithyroid peroxidase antibodies (thyroid peroxidase [TPO] antibodies were previously called thyroid antimicrosomal antibodies).

SPECIMEN: Serum (1 mL) collected in a red-top tube.

RESULT:

Increased in:
The presence of these antibodies differentiates the autoimmune origin of these disorders from non-autoimmune causes, which may influence treatment decisions
- Autoimmune disorders
- Graves' disease
- Goiter
- Hashimoto's thyroiditis
- Idiopathic myxedema
- Pernicious anemia
- Thyroid carcinoma

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Lithium may increase thyroid antibody levels.
- Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when radioimmunoassay is the test method.

DESCRIPTION: Thyroid antibodies are mainly immunoglobulin G–type antibodies. Antithyroid peroxidase antibodies bind with microsomal antigens on cells lining the microsomal membrane. They are thought to destroy thyroid tissue as a result of stimulation by lymphocytic killer cells. These antibodies are present in hypothyroid and hyperthyroid conditions. Anti-thyroglobulin antibodies are autoantibodies directed against thyroglobulin. The function of these antibodies is unclear. Both tests are normally requested together.

INDICATIONS:
- Assist in confirming suspected inflammation of thyroid gland
- Assist in the diagnosis of suspected hypothyroidism caused by thyroid tissue destruction
- Assist in the diagnosis of suspected thyroid autoimmunity in patients with other autoimmune disorders

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
Inform the patient that the test is used to assess thyroid gland function.

Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient’s endocrine and immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Note any recent procedures that can interfere with test results.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage. Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include biopsy thyroid, complete blood count, FT3, FT4, RAIU, T4, thyroid scan, thyroglobulin, TSH, TT3, and US thyroid.
- See the Endocrine and Immune System tables at the back of the book for related tests by body system.

---

**Antibodies, Cardiolipin, Immunoglobulin G, and Immunoglobulin M**

**SYNONYM/ACRONYM:** Antiphospholipid antibody, lupus anticoagulant, LA, ACA.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Immunoassay, enzyme-linked immunosorbent assay [ELISA]) Negative.

Access additional resources at davisplus.fadavis.com
DESCRIPTION: Cardiolipin antibody is one of several identified antiphospholipid antibodies. These antibodies react with proteins in the blood that are bound to phospholipid and interfere with normal blood vessel function. The two primary types of problems they cause are narrowing and irregularity of the blood vessels and blood clots in the blood vessels. Cardiolipin antibodies are found in individuals with lupus erythematosus, lupus-related conditions, infectious diseases, drug reactions, and sometimes fetal loss. Cardiolipin antibodies are often found in association with lupus anticoagulant. Increased antiphospholipid antibody levels have been found in pregnant women with lupus who have had miscarriages. The combination of noninflammatory thrombosis of blood vessels, low platelet count, and history of miscarriage is termed antiphospholipid antibody syndrome.

INDICATIONS:
- Assist in the diagnosis of antiphospholipid antibody syndrome

RESULT:

Increased in:
- Antiphospholipid antibody syndrome
- Chorea
- Drug reactions
- Epilepsy
- Infectious diseases
- Mitral valve endocarditis
- Patients with lupuslike symptoms (often antinuclear antibody–negative)
- Placental infarction
- Recurrent fetal loss (strong association with two or more occurrences)
- Recurrent venous and arterial thromboses

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Cardiolipin antibody is partially cross-reactive with syphilis reagin antibody and lupus anticoagulant. False-positive rapid plasma reagin results may occur.

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to detect the presence of antiphospholipid antibodies, which can lead to the development of blood vessel problems, complications of which include stroke, heart attack, and miscarriage.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic, immune, and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture. Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
SYNONYM/ACRONYM: Endomysial antibodies, gliadin (IgG and IgA) antibodies, EMA.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

DESCRIPTION: Gliadin is a watersoluble protein found in the gluten of wheat, rye, oats, and barley. The intestinal mucosa of certain individuals does not digest gluten, allowing a toxic

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the Lupus Foundation of America (www.lupus.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include ANA, complete blood count, fibrinogen, lupus anticoagulant antibodies, complete blood count, platelet count, protein C, protein S, and syphilis serology.

See the Hematopoietic, Immune, and Reproductive System tables in the back of the book for related tests by body system.
buildup of gliadin. Antibodies to gliadin form and result in damage to the intestinal mucosa. In severe cases, intestinal mucosa can be lost. Immunoglobulin G (IgG) and immunoglobulin A (IgA) gliadin antibodies are detectable in the serum of patients with gluten-sensitive enteropathy.

**INDICATIONS:**
- Assist in the diagnosis of asymptomatic gluten-sensitive enteropathy in some patients with dermatitis herpetiformis
- Assist in the diagnosis of gluten-sensitive enteropathies
- Assist in the diagnosis of non-tropical sprue
- Monitor dietary compliance of patients with gluten-sensitive enteropathies

**RESULT:**
**Increased in:**
- Asymptomatic gluten-sensitive enteropathy
- Celiac disease
- Dermatitis herpetiformis
- Nontropical sprue

**Decreased in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Conditions other than gluten-sensitive enteropathy can result in elevated antibody levels without corresponding histologic evidence. These conditions include Crohn’s disease, postinfection malabsorption, and food protein intolerance.
- A negative IgA gliadin result, especially with a positive IgG gliadin result in an untreated patient, does not rule out active gluten-sensitive enteropathy.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis and monitoring of gluten-sensitive enteropathies.
- Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s gastrointestinal and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of foods and the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture. Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.
POST-TEST:

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

**Nutritional considerations:** Encourage the patient with abnormal findings to consult with a qualified nutritionist to plan a gluten-free diet. This dietary planning is complex because patients are often malnourished and have other related nutritional problems.

- Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to appropriate counseling services. Provide contact information, if desired, for the Celiac Disease Foundation (celiac.org).

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include albumin, biopsy intestine, biopsy skin, calcium, capsule endoscopy, colonoscopy, D-xylose tolerance test, electrolytes, fecal analysis, fecal fat, folic acid, iron, and lactose tolerance test.
- See the Gastrointestinal and Immune System tables in the back of the book for related tests by body system.

**DESCRIPTION:**

- **Anticonvulsant Drugs: Carbamazepine, Ethosuximide, Phenobarbital, Phenytoin, Primidone, Valproic Acid**

**SYNONYM/ACRONYM:** Carbamazepine (Carbatrol, Tegretol, Tegretol XR); ethosuximide (Zarontin); phenobarbital (Luminal, Phenobarb); phenytoin (Cerebyx, Dilantin, Fenytoin, Phenytek); primidone (Mysoline); valproic acid (Depacon, Depakene, Depakote).

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

*Conventional units.
DESCRIPTION: Anticonvulsants are used to reduce the frequency and severity of seizures for patients with epilepsy. Carbamazepine is also used for controlling neurogenic pain in trigeminal neuralgia and diabetic neuropathy and for treating for bipolar disease and other neurologic and psychiatric conditions. Valproic acid is also used for some psychiatric conditions like bipolar disease and for prevention of migraine headache.

Many factors must be considered in effective dosing and monitoring of therapeutic drugs, including patient age, patient weight, interacting medications, electrolyte balance, protein levels, water balance, conditions that affect absorption and excretion, and foods, herbals, vitamins, and minerals that can either potentiate or inhibit the intended target concentration.

RESULT:

Level Response
Normal levels Therapeutic effect
Subtherapeutic levels Adjust dose as indicated
Toxic levels Adjust dose as indicated
**Carbamazepine** Hepatic impairment
**Ethosuximide** Hepatic impairment
**Phenobarbital** Hepatic impairment
**Phenytoin** Hepatic impairment
**Primidone** Hepatic impairment
**Valproic acid** Hepatic impairment

**IMPORTANT NOTE:** This information must be clearly and accurately communicated to avoid misunderstanding of the dose time in relation to the collection time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause of subtherapeutic levels, toxic levels, and misleading information used in calculation of future doses.

**INDICATIONS:**
- Assist in the diagnosis of and prevention of toxicity
- Evaluate overdose, especially in combination with ethanol
- Monitor compliance with therapeutic regimen

**CRITICAL VALUES:**

- It is important to note the adverse effects of toxic and subtherapeutic levels. Care must be taken to investigate the signs and symptoms of too little and too much medication. Note and immediately report to the health care provider (HCP) any critically increased or subtherapeutic values and related symptoms.

**Carbamazepine: Greater Than 12 mcg/mL**

Signs and symptoms of carbamazepine toxicity include respiratory depression, seizures, leukopenia, hyponatremia, hypotension, stupor, and possible coma. Possible interventions include gastric lavage (contraindicated if ileus is present); airway protection; administration of fluids.

Access additional resources at davisplus.fadavis.com
and vasopressors for hypotension; treatment of seizures with diazepam, phenobarbital, or phenytoin; cardiac monitoring; monitoring of vital signs; and discontinuing the medication. Emetics are contraindicated.

**Ethosuximide: Greater Than 100 mcg/mL**
Signs and symptoms of ethosuximide toxicity include nausea, vomiting, and lethargy. Possible interventions include administration of activated charcoal, administration of saline cathartic and gastric lavage (contraindicated if ileus is present), airway protection, hourly assessment of neurologic function, and discontinuing the medication.

**Phenobarbital: Greater Than 40 mcg/mL**
Signs and symptoms of phenobarbital toxicity include cold, clammy skin; ataxia; central nervous system (CNS) depression; hypothermia; hypotension; cyanosis; Cheyne-Stokes respiration; tachycardia; possible coma; and possible renal impairment. Possible interventions include gastric lavage, administration of activated charcoal with cathartic, airway protection, possible intubation and mechanical ventilation (especially during gastric lavage if there is no gag reflex), monitoring for hypotension, and discontinuing the medication.

**Phenytoin: Adults: Greater Than 20 mcg/mL; Neonatal: Greater Than 14 mcg/mL**
Signs and symptoms of phenytoin toxicity include double vision, nystagmus, lethargy, CNS depression, and possible coma. Possible interventions include airway support, electrocardiographic monitoring, administration of activated charcoal, gastric lavage with warm saline or tap water, administration of saline or sorbitol cathartic, and discontinuing the medication.

**Primidone: Greater Than 12 mcg/mL**
Signs and symptoms of primidone toxicity include ataxia, anemia, and CNS depression. Possible interventions include airway protection, treatment of anemia with vitamin $B_{12}$ and folate, and discontinuing the medication.

**Valproic Acid: Greater Than 120 mcg/mL**
Signs and symptoms of valproic acid toxicity include numbness, tingling, weakness, loss of appetite, and mental changes. Possible interventions include administration of activated charcoal and naloxone and discontinuing the medication.

**INTERFERING FACTORS:**
- Blood drawn in serum separator tubes (gel tubes).
- Contraindicated in patients with liver disease, and caution advised in patients with renal impairment.
- Drugs that may increase carbamazepine levels or increase risk of toxicity include acetazolamide, azithromycin, bepridil, cimetidine, danazol, diltiazem, erythromycin, felodipine, fluoxetine, fluorhymycin, fluvoxamine, gemfibrozil, isoniazid, itraconazole, josamycin, ketoconazole, loratadine, macrolides, niacinamide, nicardipine, nifedipine, nimodipine, nisoldipine, propoxyphene, ritonavir, terfenadine, troleanộmycin, valproic acid, verapamil, and viloxazine.
- Drugs that may decrease carbamazepine levels include phenobarbital, phenytoin, and primidone.
- Drugs that may increase ethosuximide levels include isoniazid, ritonavir, and valproic acid.
- Drugs that may decrease ethosuximide levels include phenobarbital, phenytoin, and primidone.
- Drugs that may increase phenobarbital levels or increase risk of
toxicity include barbital drugs, furosemide, primidone, salicylates, and valproic acid.

- Phenobarbital may affect the metabolism of other drugs, increasing their effectiveness, such as β-blockers, chloramphenicol, corticosteroids, doxycycline, griseofulvin, haloperidol, methylphenidate, phenothiazines, phenylbutazone, propoxyphene, quinidine, theophylline, tricyclic antidepressants, and valproic acid.

- Phenobarbital may affect the metabolism of other drugs, decreasing their effectiveness, such as chloramphenicol, cyclosporine, ethosuximide, oral anticoagulants, oral contraceptives, phenytoin, and theophylline.

- Phenobarbital is an active metabolite of primidone, and both drug levels should be monitored while the patient is receiving primidone to avoid either toxic or subtherapeutic levels of both medications.

- Drugs that may increase phenytoin levels or increase the risk of phenytoin toxicity include amiodarone, azapropazone, carbamazepine, chloramphenicol, cimetidine, disulfiram, ethanol, fluconazole, halothane, ibuprofen, imipramine, levodopa, metronidazole, miconazole, nifedipine, phenylbutazone, sulfonamides, trazodone, tricyclic antidepressants, and trimethoprim. Small changes in formulation (i.e., changes in brand) also may increase phenytoin levels or increase the risk of phenytoin toxicity.

- Drugs that may decrease phenytoin levels include bleomycin, carbamazepine, cisplatin, disulfiram, folic acid, intravenous fluids containing glucose, nitrofurantoin, oxacillin, rifampin, salicylates, and vinblastine.

- Primidone decreases the effectiveness of carbamazepine, ethosuximide, felbamate, lamotrigine, oral anticoagulants, oxcarbazepine, topiramate, and valproate.

- Drugs that may increase valproic acid levels or increase risk of toxicity include dicumarol, phenylbutazone, and high doses of salicylate.

- Drugs that may decrease valproic acid levels include carbamazepine, phenobarbital, phenytoin, and primidone.

### NURSING IMPLICATIONS AND PROCEDURE

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to monitor for therapeutic and toxic drug levels.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s genitourinary and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals. Note the last time and dose of medication taken.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
Direct the patient to breathe normally and to avoid unnecessary movement. Observe standard precautions, and follow the general guidelines in Appendix A. Consider recommended collection time in relation to dosing schedule. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection, noting the last dose of medication taken. Perform a venipuncture. Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage. Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient. Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Explain to the patient the importance of following the medication regimen and instructions regarding drug interactions. Instruct the patient to immediately report any unusual sensations (e.g., ataxia, dizziness, dyspnea, lethargy, rash, tremors, mental changes, weakness, or visual disturbances) to his or her HCP. Answer any questions or address any concerns voiced by the patient or family. Instruct the patient to be prepared to provide the pharmacist with a list of other medications he or she is already taking in the event that the requesting HCP prescribes a medication. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include ALT, albumin, AST, bilirubin, BUN, creatinine, complete blood count, electrolytes, GGT, and protein blood total and fractions. See the Genitourinary and Hepatobiliary Systems tables at the back of the book for related tests by body system.

*Conventional units.
DESCRIPTION: Cyclic antidepressants are used in the treatment of major depression. They have also been used effectively to treat bipolar disorder, panic disorder, attention-deficit hyperactivity disorder (ADHD), obsessive-compulsive disorder (OCD), enuresis, eating disorders (bulimia nervosa in particular), nicotine dependence (tobacco), and cocaine dependence. Numerous drug interactions occur with the cyclic antidepressants.

Many factors must be considered in effective dosing and monitoring of therapeutic drugs, including patient age, patient weight, interacting medications, electrolyte balance, protein levels, water balance, conditions that affect absorption and excretion, and foods, herbals, vitamins, and minerals that can either potentiate or inhibit the intended target concentration.

IMPORTANT NOTE: This information must be clearly and accurately communicated to avoid misunderstanding of the dose time in relation to the collection time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause of subtherapeutic levels, toxic levels, and misleading information used in calculation of future doses.

INDICATIONS:
- Assist in the diagnosis and prevention of toxicity
- Evaluate overdose, especially in combination with ethanol (Note: Doxepin abuse is unusual)
- Monitor compliance with therapeutic regimen

RESULT:

<table>

CRITICAL VALUES:
- It is important to note the adverse effects of toxic and subtherapeutic levels of antidepressants. Care must be taken to investigate signs and symptoms of too little and too much medication. Note and immediately report to the health care practitioner any critically increased or subtherapeutic values and related symptoms.

Cyclic Antidepressants:
- Amitriptyline: Greater than 300 ng/mL
- Combined amitriptyline and nortriptyline: Greater than 250 ng/mL
- Combined doxepin and desmethyl-doxepin: Greater than 150 ng/mL
- Desipramine: Greater than 300 ng/mL
- Imipramine: Greater than 250 ng/mL
Signs and symptoms of cyclic antidepressant toxicity include agitation, hallucinations, confusion, seizures, arrhythmias, hyperthermia, flushing, dilation of the pupils, and possible coma. Possible interventions include administration of activated charcoal; emesis; gastric lavage with saline; administration of physostigmine to counteract seizures, hypertension, or respiratory depression; administration of bicarbonate, propranolol, lidocaine, or phenytoin to counteract arrhythmias; and electrocardiographic monitoring.

**INTERFERING FACTORS:**
- Blood drawn in serum separator tubes (gel tubes).
- Contraindicated in patients with liver disease, and caution advised in patients with renal impairment.
- Cyclic antidepressants may potentiate the effects of oral anticoagulants.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to monitor for therapeutic and toxic drug levels.
- Obtain a history of the patient’s complaints, including a list of known allergies or sensitivities to latex.
- Obtain a history of the patient’s genitourinary and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals. Note the last time and dose of medication taken.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Consider recommended collection time in relation to dosing schedule. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection, noting the last dose of medication taken.
- Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Nutritional considerations include the avoidance of alcohol consumption.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Explain to the patient the importance of following the medication regimen and instructions regarding drug interactions. Instruct the patient to immediately report any unusual sensations (e.g., severe headache, vomiting, sweating, visual disturbances) to his or
her HCP. Blood pressure should be monitored regularly. Answer any questions or address any concerns voiced by the patient or family.

Instruct the patient to be prepared to provide the pharmacist with a list of other medications he or she is already taking in the event that the requesting HCP prescribes a medication.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ALT, albumin, AST, bilirubin, BUN, creatinine, complete blood count, electrolytes, GGT, and protein blood total and fractions.
- See the Genitourinary and Hepatobiliary Systems tables at the back of the book for related tests by body system.

---

**Antidiuretic Hormone**

**SYNONYM/ACRONYM:** Vasopressin, arginine vasopressin hormone, ADH.

**SPECIMEN:** Plasma (1 mL) collected in lavender-top (ethylenediaminetetra-acetic acid [EDTA]) tube.

**REFERENCE VALUE:** (Method: Radioimmunoassay)

**Recommendation:** This test should be ordered and interpreted with results of a serum osmolality.

*Conventional units.

**DESCRIPTION:** Anti-diuretic hormone (ADH) is formed by the hypothalamus and stored in the posterior pituitary gland. ADH is released in response to increased serum osmolality or decreased blood volume. When the hormone is active, small amounts of concentrated urine are produced; in its absence, large amounts of dilute urine are produced. Although a 1% change in serum osmolality stimulates ADH secretion, blood volume must decrease by approximately 10% for ADH secretion to be induced. Psychogenic stimuli, such as stress, pain, and anxiety, may also stimulate ADH release, but the mechanism is unclear.
**INDICATIONS:**

- Assist in the diagnosis of known or suspected malignancy associated with syndrome of inappropriate ADH secretion (SIADH), such as oat cell lung cancer, thymoma, lymphoma, leukemia, pancreatic carcinoma, prostate gland carcinoma, and intestinal carcinoma; elevated ADH levels indicate the presence of this syndrome.
- Assist in the diagnosis of known or suspected pulmonary conditions associated with SIADH, such as tuberculosis, pneumonia, and positive-pressure mechanical ventilation.
- Detect central nervous system trauma, surgery, or disease that may lead to impaired ADH secretion.
- Differentiate neurogenic (central) diabetes insipidus from nephrogenic diabetes insipidus by decreased ADH levels in neurogenic diabetes insipidus or elevated levels in nephrogenic diabetes insipidus if normal feedback mechanisms are intact.
- Evaluate polyuria or altered serum osmolality to identify possible alterations in ADH secretion as the cause.

**RESULT:**

**Increased in:**

- Numerous conditions influence the release of ADH
- Acute intermittent porphyria
- Brain tumor
- Disorders involving the central nervous system, thyroid gland, and adrenal gland
- Ectopic production (systemic neoplasm)
- Guillain-Barré syndrome
- Nephrogenic diabetes insipidus (renal system does not respond to ADH stimulation)
- Pain, stress, or exercise
- Pneumonia
- Pulmonary tuberculosis
- SIADH
- Tuberculous meningitis

**Decreased in:**

- Decreased production or secretion of ADH in response to changes in blood volume or pressure
- Nephrotic syndrome
- Pituitary (central) diabetes insipidus
- Psychogenic polydipsia

**CRITICAL VALUES:**

- Effective treatment of SIADH depends on identifying and resolving the cause of increased ADH production. Signs and symptoms of SIADH are the same as those for hyponatremia, including irritability, tremors, muscle spasms, convulsions, and neurologic changes. The patient has enough sodium, but it is diluted in excess retained water.

**INTERFERING FACTORS:**

- Drugs that may increase ADH levels include barbiturates, carbamazepine, chlorpropamide, chlortalidone, cisplatin, clofibrate, ether, furosemide, haloperidol, hydrochlorothiazide, lithium, methyclothiazide, narcotic analgesics, phenothiazides, polythiazide, tolbutamide, tricyclic antidepressants, vidarabine, vinblastine, and vincristine.
- Drugs that may decrease ADH levels include clonidine, demeclocycline, ethanol, lithium carbonate, and phenytoin.
- Recent radioactive scans or radiation within 1 week before the test can interfere with test results when radioimmunoassay is the test method.
- ADH exhibits diurnal variation, with highest levels of secretion occurring at night; first morning collection is recommended.
ADH secretion is also affected by posture, with higher levels measured while upright.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of disorders affecting urine concentration.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.
- Prepare an ice slurry in a cup or plastic bag to have ready for immediate transport of the specimen to the laboratory. Prechill the lavender-top tube in the ice slurry.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. The patient should be encouraged to be calm and in a sitting position for specimen collection. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- The sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag. Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient, as appropriate, that treatment may include diuretic therapy and fluid restriction to successfully eliminate the excess water. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include BUN, chloride, osmolality, phosphorus, potassium, sodium, TSH, uric acid, and UA.
- See the Endocrine and Genitourinary System tables at the back of the book for related tests by body system.
**SYNONYM/ACRONYM:** Antipsychotic drugs: haloperidol (Haldol, Haldol Decanoate, Haldol Lactate); antimanic drugs: lithium (Eskalith, Eskalith-CR, Lithobid).

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Chromatography for haloperidol; ion-selective electrode for lithium)

*Conventional units.

**DESCRIPTION:** Haloperidol is an antipsychotic tranquilizer used for treatment of acute and chronic psychotic disorders, Tourette’s syndrome, and hyperactive children with severe behavioral problems. Frequent monitoring is important due to the unstable relationship between dosage and circulating steady-state concentration. Lithium is used in the treatment of manic depression. Daily monitoring of lithium levels is important until the proper dosage is achieved. Lithium is cleared and reabsorbed by the kidney. Clearance is increased when sodium levels are increased and decreased in conditions associated with low sodium levels, therefore patients receiving lithium therapy should try to maintain a balanced daily
intake of sodium. Lithium levels affect other organ systems. There is a high incidence of pulmonary complications associated with lithium toxicity. Lithium can also affect cardiac conduction, producing T-wave depressions. These ECG changes are usually insignificant and reversible, and are seen in 10% to 20% of patients on lithium therapy. Chronic lithium therapy has been shown to result in enlargement of the thyroid gland in a small percentage of patients.

Many factors must be considered in effective dosing and monitoring of therapeutic drugs, including patient age, patient weight, interacting medications, electrolyte balance, protein levels, water balance, conditions that affect absorption and excretion, and foods, herbals, vitamins, and minerals that can either potentiate or inhibit the intended target concentration. Peak collection times should be documented carefully in relation to the time of medication administration.

**IMPORTANT NOTE:** This information must be clearly and accurately communicated to avoid misunderstanding of the dose time in relation to the collection time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause of subtherapeutic levels, toxic levels, and misleading information used in calculation of future doses.

**INDICATIONS:**
- Assist in the diagnosis and prevention of toxicity
- Monitor compliance with therapeutic regimen

**RESULT:**

<table>
<thead>
<tr>
<th>Level</th>
<th>Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal levels</td>
<td>Therapeutic effect</td>

<td>Adjust dose as indicated</td>
</tr>
<tr>
<td>Haloperidol</td>
<td>Hepatic impairment</td>
</tr>
<tr>
<td>Lithium</td>
<td>Renal impairment</td>
</tr>
</tbody>
</table>

**CRITICAL VALUES:**

It is important to note the adverse effects of toxic and subtherapeutic levels. Care must be taken to investigate signs and symptoms of not enough medication and too much medication. Note and immediately report to the health care provider (HCP) any critically increased or subtherapeutic values and related symptoms.

**Haloperidol: Greater Than 50 ng/mL**

Signs and symptoms of haloperidol toxicity include hypotension, myocardial depression, respiratory depression, and extrapyramidal neuromuscular reactions. Possible interventions include emesis (contraindicated in the absence of gag reflex or central nervous system depression or excitation), and gastric...
lavage followed by administration of activated charcoal.

**Lithium: Greater Than 1.5 mEq/L**

Signs and symptoms of lithium toxicity include ataxia, coarse tremors, muscle weakness, vomiting, diarrhea, confusion, convulsions, stupor, T-wave flattening, loss of consciousness, and possible coma. Possible interventions include administration of activated charcoal, gastric lavage, and administration of intravenous fluids with diuresis.

**INTERFERING FACTORS:**
- Blood drawn in serum separator tubes (gel tubes).
- Contraindicated in patients with liver disease, and caution advised in patients with renal impairment.
- Haloperidol may increase levels of tricyclic antidepressants and increase the risk of lithium toxicity.
- Drugs that may increase lithium levels include angiotensin-converting enzyme inhibitors, some NSAIDs, and thiazide diuretics.
- Drugs and substances that may decrease lithium levels include acetazolamide, osmotic diuretics, theophylline, and caffeine.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to monitor for therapeutic and toxic drug levels.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s genitourinary and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals. Note the last time and dose of medication taken.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Consider recommended collection time in relation to dosing schedule. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection, noting the last dose of medication taken. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Nutritional considerations include the avoidance of alcohol consumption.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Explain to the patient the importance of following the medication regimen and instructions regarding drug interactions.
- Instruct the patient receiving haloperidol to immediately report any unusual symptoms (e.g., arrhythmias, blurred vision, dry eyes, repetitive uncontrolled movements) to his or her HCP.
- Instruct the patient receiving lithium to immediately report any unusual symptoms (e.g., anorexia, nausea, vomiting, diarrhea, dizziness, drowsiness, dysarthria, tremor, muscle twitching, visual disturbances) to his or her HCP.
- Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient to be prepared to provide the pharmacist with a list of other medications he or she is already taking in the event that the requesting HCP prescribes a medication.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related laboratory tests include albumin, BUN, calcium, creatinine, glucose, magnesium, osmolality, potassium, sodium, T4, and TSH.
- See the Genitourinary and Hepatobiliary System tables in the back of the book for related tests by body system.

---

**Antithrombin III**

**SYNONYM/ACRONYM:** Heparin cofactor assay, AT-III.

**SPECIMEN:** Plasma (1 mL) collected in a blue-top (sodium citrate) tube.

**REFERENCE VALUE:** (Method: Radioimmunodiffusion)

<table>
<thead>
<tr>

</tbody>
</table>
Antithrombin III (AT-III) can inhibit thrombin and factors IX, X, XI, and XII. It is a heparin cofactor, interacting with heparin and thrombin. AT-III acts to increase the rate at which thrombin is neutralized or inhibited, and it decreases the total quantity of thrombin inhibited. Patients with low levels of AT-III show some level of resistance to heparin therapy and are at risk for venous thrombosis.

**DESCRIPTION:**

Antithrombin III (AT-III) can inhibit thrombin and factors IX, X, XI, and XII. It is a heparin cofactor, interacting with heparin and thrombin. AT-III acts to increase the rate at which thrombin is neutralized or inhibited, and it decreases the total quantity of thrombin inhibited. Patients with low levels of AT-III show some level of resistance to heparin therapy and are at risk for venous thrombosis.

**INDICATIONS:**
- Investigate tendency for thrombosis

**RESULT:**

*Increased in:*
- Acute hepatitis following renal transplantation
- Renal transplantation
- Vitamin K deficiency *(decreased consumption due to impaired coagulation factor function)*

*Decreased in:*
- Carcinoma
- Chronic liver failure *(decreased synthesis)*
- Cirrhosis *(decreased synthesis)*
- Congenital deficiency
- Disseminated intravascular coagulation *(increased consumption)*
- Liver transplantation or partial hepatectomy *(decreased synthesis)*
- Nephrotic syndrome *(increased loss)*
- Pulmonary embolism *(increased consumption)*
- Venous thrombosis *(increased consumption)*

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase AT-III levels include anabolic steroids, gemfibrozil, and warfarin (coumadin).
- Drugs that may decrease AT-III levels include asparaginase, estrogens, heparin, and oral contraceptives.
- Placement of the tourniquet for longer than 1 min can result in venous stasis and changes in the concentration of the plasma proteins to be measured. Platelet activation may also occur under these conditions, resulting in erroneous measurements.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of coagulation disorders.
- Observe the patient’s hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions unless by medical direction.
**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture

**Important note:** Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It is important to ask the laboratory which concentration it recommends, because each concentration will have its own specific reference range. When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and red-top tubes. When coagulation testing is the only work to be done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with tissue thromboplastin.

- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed samples stored in unopened tubes is that testing should be completed within 1 to 4 hr of collection.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include antibodies cardioliopin, echocardiography, lung perfusion scan, aPTT, protein C, protein S, venography lower extremities, and vitamin K.
- See the Hematopoietic System table at the back of the book for related tests by body system.

### α₁-Antitrypsin and α₁-Antitrypsin Phenotyping

**SYNONYM/ACRONYM:** α₁-antitrypsin: A₁AT, α₁-AT, AAT; α₁-antitrypsin phenotyping: A₁AT phenotype, α₁-AT phenotype, AAT phenotype, Pi phenotype.

**SPECIMEN:** Serum (1 mL) for α₁-antitrypsin (α₁-AT) and serum (2 mL) for α₁-AT phenotyping collected in a red- or tiger-top tube.
α₁-Antitrypsin and α₁-Antitrypsin Phenotyping

**REFERENCE VALUE:** (Method: Rate nephelometry for α₁-AT, isoelectric focusing/high-resolution electrophoresis for α₁-AT phenotyping)

### α₁-Antitrypsin Phenotyping

There are three major protease inhibitor phenotypes:
- **MM**—Normal
- **SS**—Intermediate; heterozygous
- **ZZ**—Markedly abnormal; homozygous

The total level of measurable α₁-AT varies with genotype. The effects of α₁-AT deficiency depend on the patient’s personal habits, but are most severe in patients who smoke tobacco.

**DESCRIPTION:** α₁-AT is the main glycoprotein produced by the liver. Its inhibitory function is directed against proteolytic enzymes, such as trypsin, elastin, and plasmin, released by alveolar macrophages and bacteria. In the absence of α₁-AT, functional tissue is destroyed by proteolytic enzymes and replaced with excessive connective tissue. Emphysema develops at an earlier age in α₁-AT–deficient emphysema patients than in other emphysema patients. α₁-AT deficiency is passed on as an autosomal recessive trait. Inherited deficiencies are associated early in life with development of lung and liver disorders. In the pediatric population, the ZZ phenotype usually presents as liver disease, cholestasis, and cirrhosis. Greater than 80% of ZZ-deficient individuals ultimately develop chronic lung or liver disease. It is important to identify inherited deficiencies early in life. Typically, α₁-AT–deficient patients have circulating levels less than 50 mg/dL. Patients who have α₁-AT values less than 140 mg/dL should be phenotyped.

Elevated levels are found in normal individuals when an inflammatory process, such as rheumatoid arthritis, bacterial infection, neoplasm, or vasculitis, is present. Decreased levels are found in affected patients with chronic obstructive pulmonary disease (COPD) and in children with cirrhosis of the liver. Deficiency of this enzyme is the most common cause of liver disease in the pediatric population. Decreased α₁-AT levels also may be elevated into the normal range in heterozygous α₁-AT–deficient patients during concurrent infection, pregnancy, estrogen therapy, steroid therapy, cancer, and postoperative periods. Homozygous α₁-AT–deficient patients do not show such an elevation.

Access additional resources at davisplus.fadavis.com
INDICATIONS:
• Assist in establishing a diagnosis of COPD
• Assist in establishing a diagnosis of liver disease
• Detect hereditary absence or deficiency of $\alpha_1$-AT

RESULT:
**Increased in:**
- Increases are rapid and nonspecific in response to inflammation
  - Acute and chronic inflammatory conditions
  - Carcinomas
  - Estrogen therapy
  - Postoperative recovery
  - Pregnancy
  - Steroid therapy
  - Stress (extreme physical)

**Decreased in:**
- Liver disease affects synthesis of this protein
  - COPD
  - Homozygous $\alpha_1$-AT–deficient patients
  - Liver disease (severe)
  - Liver cirrhosis (child)
  - Malnutrition
  - Nephrotic syndrome

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- $\alpha_1$-AT is an acute-phase reactant protein, and any inflammatory process elevates levels. If a serum C-reactive protein is performed simultaneously and is positive, the patient should be retested for $\alpha_1$-AT in 10 to 14 days.
- Rheumatoid factor causes false-positive elevations.
- Drugs that may increase serum $\alpha_1$-AT levels include aminocaproic acid, estrogen therapy, oral contraceptives (high-dose preparations), oxymetholone, streptokinase, tamoxifen, and typhoid vaccine.

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to identify COPD and liver disease associated with $\alpha_1$-antitrypsin deficiency.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hepatobiliary and respiratory system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals. Oral contraceptives should be withheld 24 hr before the specimen is collected, although this restriction should first be confirmed with the health care provider (HCP) ordering the test.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain to the patient that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient.
demographics, date, and time of collection. Perform a venipuncture. Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage. Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual medication as directed by the HCP.

**Nutritional considerations:** Malnutrition is commonly seen in \( \alpha_1 \)-AT–deficient patients with severe respiratory disease for many reasons, including fatigue, lack of appetite, and gastrointestinal distress. Research has estimated that the daily caloric intake required for respiration in patients with COPD is 10 times higher than that required of normal individuals. Inadequate nutrition can result in hypophosphatemia, especially in the respirator-dependent patient. During periods of starvation, phosphorus leaves the intracellular space and moves outside the tissue, resulting in dangerously decreased phosphorus levels. Adequate intake of vitamins A and C is important to prevent pulmonary infection and to decrease the extent of lung tissue damage. The importance of following the prescribed diet should be stressed to the patient and caregiver.

**Nutritional considerations:** Water balance must be closely monitored in \( \alpha_1 \)-AT–deficient patients with COPD. Fluid retention can lead to pulmonary edema. Educate the patient with abnormal findings in preventive measures for protection of the lungs (e.g., avoid contact with persons who have respiratory or other infections; avoid the use of tobacco; avoid areas having highly polluted air; and avoid work environments with hazards such as fumes, dust, and other respiratory pollutants).

Instruct the affected patient in deep breathing and pursed-lip breathing to enhance breathing patterns as appropriate. Inform the patient of smoking cessation programs, as appropriate.

Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Because decreased \( \alpha_1 \)-AT can be an inherited disorder, it may be appropriate to recommend resources for genetic counseling if levels less than 140 mg/dL are reported. It may also be appropriate to inform the patient that \( \alpha_1 \)-AT phenotype testing can be performed on family members to determine the homozygous or heterozygous nature of the deficiency.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of the importance of medical follow-up, and suggest ongoing support resources to assist the patient in coping with chronic illness and possible early death. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ACE, anion gap, arterial/alveolar oxygen ratio, biopsy lung, blood gases, blood pool imaging, bronchoscopy, electrolytes, lung perfusion scan, lung ventilation scan, osmolality, PET heart, phosphorus, PFTs, plethysmography, and pulse oximetry, if COPD is suspected. ALT, albumin, ALP, ammonia, bilirubin and fractions, biopsy liver, cholangiography percutaneous transhepatic, cholangiography post-op, CT biliary tract and liver, ERCP, GGT, hepatobiliary scan, liver and spleen scan, protein and fractions, PT/INR, and US liver, if liver disease is suspected.

See the Hepatobiliary and Respiratory System tables at the back of the book for related tests by body system.
**Apolipoprotein A and B**

**SYNONYM/ACRONYM:** Apo A and Apo B.

**DESCRIPTION:** Apolipoproteins assist in the regulation of lipid metabolism by activating and inhibiting enzymes required for this process. The apolipoproteins also help keep lipids in solution as they circulate in the blood and direct the lipids toward the correct target organs and tissues in the body. Apolipoprotein A (Apo A), the major component of high-density lipoprotein (HDL), is synthesized in the liver and intestines. Apo A-I activates the enzyme lecithin-cholesterol acyltransferase (LCAT), whereas Apo A-II inhibits LCAT. It is believed that Apo A measurements may be more important than HDL cholesterol measurements as a predictor of coronary artery disease (CAD). There is an inverse relationship...
between Apo A levels and risk for developing CAD. Because of difficulties with method standardization, the above-listed reference ranges should be used as a rough guide in assessing abnormal conditions. Values for African Americans are 5 to 10 mg/dL higher than values for whites. Apolipoprotein B (Apo B), the major component of the low-density lipoproteins (chylomicrons, LDL, and very-low-density lipoprotein), is synthesized in the liver and intestines.

**INDICATIONS:**
- Evaluation for risk of CAD

**RESULT:**
*The exact functional role of apolipoproteins is unclear but there is a very strong association between Apo A and HDL “good” cholesterol and Apo B and LDL “bad” cholesterol*

**Apolipoprotein A**

*Increased in:*
- Familial hyper-α-lipoproteinemia
- Weight reduction

*Decreased in:*
- Abetalipoproteinemia
- Cholestasis
- Chronic renal failure
- Diabetes (uncontrolled)
- Diet high in carbohydrates or polyunsaturated fats
- Familial deficiencies of related enzymes and lipoproteins
- Hepatocellular disorders
- Hypertriglyceridemia
- Nephrotic syndrome
- Premature coronary heart disease
- Smoking

**Apolipoprotein B**

*Increased in:*
- Anorexia nervosa
- Cushing’s syndrome

*Decreased in:*
- Diabetes
- Dysglobulinemia
- Emotional stress
- Hepatic disease
- Hepatic obstruction
- Hyperlipoproteinemasias
- Hypothyroidism
- Infantile hypercalcemia
- Nephrotic syndrome
- Porphyria
- Pregnancy
- Premature CAD
- Renal failure
- Werner’s syndrome

**Critical Values:** N/A

**INTERFERING FACTORS:**
- Drugs and substances that may increase Apo A levels include anticonvulsants, beclobrate, bezafibrate, ciprofibrate, estrogens, furosemide, lovastatin, pravastatin, prednisolone, simvastatin, and ethanol (abuse).
- Drugs that may decrease Apo A levels include androgens, β-blockers, diuretics, and probucol.
- Drugs that may increase Apo B levels include amiodarone, androgens, β-blockers, catecholamines, cyclosporine, diuretics, ethanol (abuse), etretinate, glucocorticosteroids, oral contraceptives, and phenobarbital.
- Drugs that may decrease Apo B levels include beclobrate,
captopril, cholestyramine, fibrates, ketanserin, lovastatin, niacin, nifedipine, pravastatin, prazosin, probucol, and simvastatin.

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess and monitor risk for coronary artery disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medication, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- The patient should abstain from food for 6 to 12 hr before specimen collection.
- There are no fluid or medication restrictions unless by medical direction.

**INTRATEST:**
- Ensure that the patient has complied with dietary or activity restrictions, and pretesting preparations; assure that food has been restricted for at least 6 to 12 hr prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- Instruct the patient to resume usual diet as directed by the health care provider (HCP).
- Nutritional considerations: Decreased Apo A and/or increased Apo B levels may be associated with CAD. Nutritional therapy is recommended for individuals identified to be at high risk for developing CAD. Overweight patients should be encouraged to achieve a normal weight. The American Heart Association Step 1 and Step 2 diets may be helpful in achieving a goal of reducing total cholesterol and triglyceride levels. The Step 1 diet emphasizes a reduction in foods high in saturated fats and cholesterol. Red meats, eggs, and dairy products are the major sources of saturated fats and cholesterol. If triglycerides are also elevated, the patient should be advised to eliminate or reduce alcohol and simple carbohydrates from the diet. The Step 2 diet recommends stricter reductions.
- A written report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as
appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include antiarrhythmic drugs, AST, ANP, BNP, blood gases, CRP, calcium and ionized calcium, cholesterol (total, HDL, and LDL), CK and isoenzymes, CT scoring, echocardiography, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI chest, myocardial infarct scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, triglycerides, and troponin.

See the Cardiovascular System table at the back of the book for related tests by body system.

SYNONYM/ACRONYM: Joint study.

AREA OF APPLICATION: Shoulder, elbow, wrist, hip, knee, ankle, temporomandibular joint.

CONTRAST: Iodinated or gadolinium.

DESCRIPTION: An arthrogram evaluates the cartilage, ligaments, and bony structures that compose a joint. After local anesthesia is administered to the area of interest, a fluoroscopically guided small-gauge needle is inserted into the joint space. Fluid in the joint space is aspirated and sent to the laboratory for analysis. Contrast medium is inserted into the joint space to outline the soft tissue structures and the contour of the joint. After brief exercise of the joint, radiographs or magnetic resonance images (MRIs) are obtained. Arthrograms are used primarily for assessment of persistent, unexplained joint discomfort.

INDICATIONS:

- Evaluate pain, swelling, or dysfunction of a joint
- Monitor disease progression

RESULT:

Normal findings in:

- Normal bursae, menisci, ligaments, and articular cartilage of the joint (note: the cartilaginous surfaces and menisci should be smooth, without evidence of erosion, tears, or disintegration)

Abnormal findings in:

- Arthritis
- Cysts
- Diseases of the cartilage (chondromalacia)
- Injury to the ligaments

Access additional resources at davisplus.fadavis.com
• Joint derangement
• Meniscal tears or laceration
• Muscle tears
• Osteochondral fractures
• Osteochondritis dissecans
• Synovial tumor
• Synovitis

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

**This procedure is contraindicated for:**

- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids or the use of a nonionic contrast medium.
- Patients with metal in their body, such as shrapnel or ferrous metal in the eye.
- Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI.
- Use of gadolinium-based contrast agents (GBCA) is contraindicated in patients with acute or chronic severe renal insufficiency (glomerular filtration rate less than 30 mL/min/1.73 m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non–contrast-enhanced diagnostic studies.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Patients with bleeding disorders, active arthritis, or joint infections.

**Factors that may impair clear imaging:**

- Metallic objects within the examination field which may inhibit organ visualization and can produce unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

**Other considerations:**

- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the examination room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

---

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the joint being examined.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics and dyes.
- Obtain a history of results of the patient’s musculoskeletal system, symptoms, and previously performed laboratory tests and diagnostic and surgical procedures. Ensure that the results of blood tests are obtained and recorded before the procedure, especially coagulation tests, BUN, and creatinine, if
contrast medium is to be used. Obtain a history of renal dysfunction if the use of GBCA is anticipated.

Ensure the results of BUN, creatinine and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals. (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.

Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in the radiology department by a HCP and takes approximately 30 to 60 min.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions unless by medical direction.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRA-TEST:**

Ensure that the patient has removed all external metallic objects prior to the procedure.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Observe standard precautions and follow the general guidelines in Appendix A. Instruct the patient to cooperate fully and to follow directions.

Place the patient on the table in a supine position.

The skin surrounding the joint is aseptically cleaned and anesthetized.

A small-gauge needle is inserted into the joint space.

Any fluid in the space is aspirated and sent to the laboratory for analysis.

Contrast medium is inserted into the joint space with fluoroscopic guidance.

The needle is removed, and the joint is exercised to help distribute the contrast medium.

X-rays or MRIs are taken of the joint.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

During x-ray imaging, lead protection is placed over the gonads to prevent their irradiation.

If MRI images are taken, supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.

**POST-TEST:**

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Assess the joint for swelling after the test. Apply ice as needed.

Instruct the patient to use a mild analgesic (aspirin, acetaminophen), as ordered, if there is discomfort.

Advise the patient to avoid strenuous activity until approved by the HCP.

Instruct the patient to notify the HCP if fever, increased pain, drainage, warmth, edema, or swelling of the joint occurs.

Inform the patient that noises from the joint after the procedure are common and should disappear 24 to 48 hr after the procedure.

Recognize anxiety related to test results. Discuss the implications of
abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- Reinforce information given by the patient’s HCP regarding further testing, treatment or referral to another HCP.
- Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include antibodies anticyclic citrullinated peptide, ANA, arthroscopy, BMD, bone scan, BUN, CRP, creatinine, ESR, MRI musculoskeletal, PT/INR, radiography bone, RF, synovial fluid analysis, and uric acid.
- Refer to the Musculoskeletal System table at the back of the book for related tests by body system.

### Arthroscopy

**SYNONYM/ACRONYM:** N/A.

**AREA OF APPLICATION:** Joints.

**CONTRAST:** None.

**DESCRIPTION:** Arthroscopy provides direct visualization of a joint through the use of a fiberoptic endoscope. The arthroscope has a light, fiberoptics, and lenses; it connects to a monitor, and the images are recorded for future study and comparison. This procedure is used for inspection of joint structures, performance of a biopsy, and surgical repairs to the joint. Meniscus removal, spur removal, and ligamentous repair are some of the surgical procedures that may be performed. This procedure is most commonly performed to diagnose athletic injuries and acute or chronic joint disorders. Because arthroscopy allows direct visualization, degenerative processes can be accurately differentiated from injuries. A local anesthetic allows the arthroscope to be inserted through the skin with minimal discomfort. This procedure may also be done under a spinal or general anesthetic, especially if surgery is anticipated.

**INDICATIONS:**
- Detect torn ligament or tendon
- Evaluate joint pain and damaged cartilage
- Evaluate meniscal, patellar, condylar, extrasynovial, and synovial injuries or diseases of the knee
• Evaluate the extent of arthritis
• Evaluate the presence of gout
• Monitor effectiveness of therapy
• Remove loose objects

RESULT:

Normal findings in:
• Normal muscle, ligament, cartilage, synovial, and tendon structures of the joint

Abnormal findings in:
• Arthritis
• Chondromalacia
• Cysts
• Degenerative joint changes
• Ganglion or Baker’s cyst
• Gout or pseudogout
• Joint tumors
• Loose bodies
• Meniscal disease
• Osteoarthritis
• Osteochondritis
• Rheumatoid arthritis
• Subluxation, fracture, or dislocation
• Synovitis
• Torn cartilage
• Torn ligament
• Torn rotator cuff
• Trapped synovium

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with bleeding disorders, active arthritis, or cardiac conditions
• Patients with joint infection or skin infection near proposed arthroscopic site
• Patients who have had an arthrogram within the last 14 days

Factors that may impair clear imaging:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

• Fibrous ankylosis of the joint preventing effective use of the arthroscope
• Joints with flexion of less than 50°

Other considerations:
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➧ Inform the patient that the procedure assesses the joint to be examined.
➧ Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex and anesthetics.
➧ Obtain a history of the patient’s musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
➧ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
➧ Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
➧ Review the procedure with the patient. Address concerns about pain and explain that some discomfort and pain may be experienced during the test. Inform the patient that the procedure is performed by a HCP, usually in the radiology department, and takes approximately 30 to 60 min.
Explain that a preprocedure sedative may be administered to promote relaxation, as ordered. 

Crutch walking should be taught before the procedure if it is anticipated postoperatively. 

The joint area and areas 5 to 6 in. above and below the joint are shaved and prepared for the procedure. 

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. 

Instruct the patient to refrain from food and fluids for 6 to 8 hr before the test. Protocols may vary from facility to facility. 

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications. 

**INTRATEST:** 

Ensure the patient has complied with food and fluid restrictions for at least 6 to 8 hr prior to the procedure. 

Resuscitation equipment and patient monitoring equipment must be available. 

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided. 

The extremity is scrubbed, elevated, and wrapped with an elastic bandage from the distal portion of the extremity to the proximal portion to drain as much blood from the limb as possible. 

A pneumatic tourniquet placed around the proximal portion of the limb is inflated, and the elastic bandage is removed. 

As an alternative to a tourniquet, a mixture of lidocaine with epinephrine and sterile normal saline may be instilled into the joint to help reduce bleeding. 

The joint is placed in a 45° angle, and a local anesthetic is administered. 

A small incision is made in the skin in the lateral or medial aspect of the joint. 

The arthroscope is inserted into the joint spaces. The joint is manipulated as it is visualized. Added puncture sites may be needed to provide a full view of the joint. 

Biopsy or treatment can be performed at this time, and photographs should be taken for future reference. 

After inspection, specimens may be obtained for cytologic and microbiologic study. All specimens are placed in appropriate containers, labeled with the corresponding patient demographics, date and time of collection, site location, and promptly sent to the laboratory. 

The joint is irrigated, and the arthroscope is removed. Manual pressure is applied to the joint to remove remaining irrigation solution. 

The incision sites are sutured, and a pressure dressing is applied. 

Sterile gloves and gowns are worn throughout the procedure. 

**POST-TEST:** 

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient. 

Advise the patient to avoid strenuous activity involving the joint until approved by the HCP. 

Instruct the patient to resume normal diet and medications, as directed by the HCP. 

Monitor the patient's circulation and sensations in the joint area. 

Instruct the patient to immediately report symptoms such as fever, excessive bleeding, difficulty breathing, incision site redness, swelling, and tenderness. 

Instruct the patient to elevate the joint when sitting and to avoid overbending of the joint to reduce swelling. 

Instruct the patient to take an analgesic for joint discomfort after the procedure; ice bags may be used to reduce postprocedure swelling. 

Inform the patient to shower after 48 hr but to avoid a tub bath until after his or her appointment with the HCP. 

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. 

Reinforce information given by the patient's HCP regarding further testing.
Aspartate Aminotransferase

SYNONYM/ACRONYM: Serum glutamic-oxaloacetic transaminase, AST, SGOT.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Spectrophotometry, enzymatic at 37°C)

DESCRIPTION: Aspartate aminotransferase (AST) is an enzyme that catalyzes the reversible transfer of an amino group between aspartate and \(\alpha\)-ketoglutaric acid. It was formerly known as serum glutamic-oxaloacetic transaminase (SGOT). AST exists in large amounts in liver and myocardial cells and in smaller but significant amounts in skeletal muscle, kidneys, pancreas, and the brain. Serum AST rises when there is cellular damage to the tissues where the enzyme is found. AST values greater than 500 units/L are usually associated with hepatitis and other hepatocellular diseases in an acute phase. AST levels are very elevated at birth and decrease with age. Note: Measurement of AST in evaluation of myocardial infarction has been replaced by more sensitive tests, such as creatine kinase–MB fraction (CK-MB) and troponin.

INDICATIONS:
- Assist in the diagnosis of disorders or injuries involving the tissues where AST is normally found

RELATED MONOGRAPHS:
- Related tests include anti-cyclic citrullinated peptide, ANA, arthrogram, BMD, bone scan, CRP, ESR, MRI musculoskeletal, radiography of the bone, RF, synovial fluid analysis, and uric acid.
- Refer to the Musculoskeletal System table at the back of the book for related tests by body system.
CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may increase AST levels by causing cholestasis include amitriptyline, anabolic steroids, androgens, benzodiazepines, chlorothiazide, chlorpropamide, dapsone, erythromycin, estrogens, ethionamide, gold salts, imipramine, mercaptopurine, nitrofurans, oral contraceptives, penicillins, phenothiazines, progesterone, proproxyphene, sulfonamides, tamoxifen, and tolbutamide.
• Drugs that may increase AST levels by causing hepatocellular damage include acetaminophen (toxic), acetylsalicylic acid, allopurinol, amiodarone, anabolic steroids, anticonvulsants, asparaginase, azithromycin, bromocriptine, captopril, cephalosporins, chloramphenicol, clindamycin, clofibrate, danazol, enflurane, ethambutol, ethionamide, fenofibrate, fluconazole, fluoroquinolones, foscarnet, gentamicin, indomethacin, interferon, interleukin-2, levamisole, levodopa, lincomycin, low-molecular-weight heparin, methyldopa, monoamine oxidase inhibitors, naproxen, nifedipine, nitrofurans, oral contraceptives, probenecid, procainamide, quinine, ranitidine, retinol, ritodrine, sulfonylureas, tetracyclines, tobramycin, and verapamil.
• Hemolysis falsely increases AST levels.

RESULT:
AST is released from any damaged cell in which it is stored so conditions that affect the liver, kidneys, heart, or skeletal muscle and cause cellular destruction demonstrate elevated AST levels.

Significantly increased in (greater than five times normal levels):
• Acute hepatitis
• Acute hepatocellular disease
• Acute pancreatitis
• Shock

Moderately increased in (three to five times normal levels):
• Biliary tract obstruction
• Cardiac arrhythmias
• Chronic hepatitis
• Congestive heart failure
• Dermatomyositis
• Liver tumors
• Muscular dystrophy

Slightly increased in (two to three times normal):
• Cerebrovascular accident
• Cirrhosis, fatty liver
• Delirium tremens
• Hemolytic anemia
• Pericarditis
• Pulmonary infarction

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
Inform the patient that the test is primarily used to assess liver function.

Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient’s cardiovascular and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain to the patient that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions unless by medical direction.

INTRA-TEST:

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Nutritional considerations: Increased AST levels may be associated with liver disease. Dietary recommendations may be indicated and will vary depending on the condition and its severity. Currently, there are no specific medications that can be given to cure hepatitis, but elimination of alcohol ingestion and a diet optimized for convalescence are commonly included in the treatment plan. A high-calorie, high-protein, moderate-fat diet with a high fluid intake is often recommended for patients with hepatitis. Treatment of cirrhosis is different; a low-protein diet may be in order if the patient’s liver can no longer process the end products of protein metabolism. A diet of soft foods may be required if esophageal varices have developed. Ammonia levels may be used to determine whether protein should be added to or reduced from the diet. Patients should be encouraged to eat simple carbohydrates and emulsified fats (as in homogenized milk or eggs), as opposed to complex carbohydrates (e.g., starch, fiber, and glycogen [animal carbohydrates]) and complex fats, which require additional bile to emulsify them so that they can be used. The cirrhotic patient should be observed carefully for the development of ascites, in which case fluid and electrolyte balance requires strict attention.

Nutritional considerations: Increased AST levels may be associated with coronary artery disease (CAD). Nutritional therapy is recommended for individuals identified to be at high risk for CAD. Overweight patients should be encouraged to achieve a normal weight. The American Heart Association Step 1 and Step 2 diets may be helpful in achieving a
goal of reducing total cholesterol and triglyceride levels. The Step 1 diet emphasizes a reduction in foods high in saturated fats and cholesterol. Red meats, eggs, and dairy products are the major sources of saturated fats and cholesterol. If triglycerides are also elevated, the patient should be advised to eliminate or reduce alcohol and simple carbohydrates from the diet. The Step 2 diet recommends stricter reductions.

Instruct the patient to immediately report chest pain and changes in breathing pattern to the HCP.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include acetaminophen, ALT, albumin, ALP, ammonia, AMA/ASMA, α1-antitrypsin/phenotyping, bilirubin and fractions, biopsy liver, cholangiography percutaneous transhepatic, cholangiography post-op, CT biliary tract and liver, ERCP, ethanol, ferritin, GGT, hepatitis antigens and antibodies, hepatobiliary scan, iron/total iron-binding capacity, liver and spleen scan, protein and fractions, PT/INR, and US liver, if liver disease is suspected; and antiarrhythmic drugs, apolipoprotein A and B, ANP, BNP, blood gases, CRP, calcium/ionized calcium, CT scoring, cholesterol (total, HDL, and LDL), CK, echocardiography, Holter monitor, homocysteine, LDH, MRI chest, myocardial infarct scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, triglycerides, and troponin if myocardial infarction is suspected.

See the Cardiovascular and Hepatobiliary System tables in the back of the book for related tests by body system.

---

**Atrial Natriuretic Peptide**

**SYNONYM/ACRONYM:** Atrial natriuretic hormone, atrial natriuretic factor, ANF, ANH.

**SPECIMEN:** Plasma (1 mL) collected in a chilled, lavender-top tube. Specimen should be transported tightly capped and in an ice slurry.

**REFERENCE VALUE:** (Method: Radioimmunoassay)

**Audiometry, Hearing Loss**

**SYNONYM/ACRONYM:** N/A.

**AREA OF APPLICATION:** Ears.

**CONTRAST:** N/A.

**DESCRIPTION:** Tests to estimate hearing ability can be performed on patients of any age, e.g., at birth before discharge from a hospital or birthing center, as part of a school screening program, or as adults if indicated. Hearing loss audiometry includes quantitative testing for a hearing deficit. An audiometer is used to measure and record thresholds of hearing by air conduction and bone conduction tests. The test results determine if hearing loss is conductive, sensorineural, or a combination of both. An elevated air-conduction threshold with a normal bone-conduction threshold indicates a conductive hearing loss. An equally elevated threshold for both air and bone conduction indicates a sensorineural hearing loss. An elevated threshold of air conduction that is greater than an elevated threshold of bone conduction indicates a composite of both types of hearing loss. A conductive hearing loss is caused by an abnormality in the external auditory canal or middle ear, and a sensorineural hearing loss by an abnormality in the inner ear or of the VIII (auditory) nerve. Sensorineural hearing loss can be further differentiated clinically by sensory (cochlear) or neural (VIII nerve) lesions. Additional information for comparing and differentiating between conductive and sensorineural hearing loss can be obtained from hearing loss tuning fork tests.
INDICATIONS:
- Determine the need for a type of hearing aid and evaluate its effectiveness
- Determine the type and extent of hearing loss and if further radiologic, audiologic, or vestibular procedures are needed to identify the cause
- Evaluate communication disabilities and plan for rehabilitation interventions
- Evaluate degree and extent of preoperative and postoperative hearing loss following stapedectomy in patients with otosclerosis
- Screen for hearing loss in infants and children and determine the need for a referral to an audiologist

*dB = decibel

Normal findings in:
- Normal pure tone average of 0 to 20 dB for infants, children, or adults.

Abnormal findings in:
- Causes of conductive hearing loss
  - Obstruction of external ear canal
  - Otitis externa
  - Otitis media
  - Otosclerosis
- Causes of sensorineural hearing loss
  - Congenital damage or malformations of the inner ear
  - Ototoxic drugs
  - Serious infections
  - Trauma to the inner ear
  - Tumor
  - Vascular disorders
- Obstructions of the ear canal by cerumen or other material or object will affect decibel (dB) perception.
- Noisy environment or extraneous movements can affect results.
- Tinnitus or other sensations can cause abnormal responses.
- Improper earphone fit or audiometer calibration can affect results.
- Failure to follow pretesting preparations before the procedure may cause the procedure to be canceled or repeated.

CRITICAL VALUES: N/A

INTERFERING FACTORS:
Factors that may impair the results of the examination:
- Inability of the patient to cooperate or remain still during the procedure because of age, language barriers, significant pain, or mental status may interfere with the test results.
- Positive identification of the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient/caregiver that the procedure detects hearing loss.
- Obtain a history of the patient's complaints, including a list of known allergens.
Obtain a history of the patient’s known or suspected hearing loss, including type and cause; ear conditions with treatment regimens; ear surgery; and other tests and procedures to assess and diagnose auditory deficit.

Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Address concerns about pain and explain that no discomfort will be experienced during the test. Inform the patient that an audiologist or health care provider (HCP) specializing in this procedure performs the test in a quiet, soundproof room, and that the test can take up 20 min to evaluate both ears. Explain that each ear will be tested separately by using earphones and/or a device placed behind the ear to deliver sounds of varying intensities. Address concerns about claustrophobia, as appropriate. Explain and demonstrate to the patient how to communicate with the audiologist and how to exit from the room.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions unless by medical direction.

Ensure that the external auditory canal is clear of impacted cerumen.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRA.TEST:**

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still during the procedure because movement produces unreliable results.

Perform otoscopy examination to ensure that the external ear canal is free from any obstruction (see monograph titled “Otoscopy”).

Test for closure of the canal from the pressure of the earphones by compressing the tragus. Tendency for the canal to close (often the case in children and elderly patients) can be corrected by the careful insertion of a small stiff plastic tube into the anterior canal.

Place the patient in a sitting position in comfortable proximity to the audiometer in a soundproof room. The ear not being tested is masked to prevent crossover of test tones and the earphones are positioned on the head and over the ear canals. Infants and children may be tested using earphones that are inserted into the ear, unless contraindicated. An oscillating probe may be placed over the mastoid process behind the ear or on the forehead if bone conduction testing is to be performed as part of the hearing assessment.

Start the test by providing a trial tone of 15–20 dB above the expected threshold to the ear for 1 to 2 sec to familiarize the patient with the sounds. Instruct the patient to press the button each time a tone is heard, no matter how loudly or faintly it is perceived. If no response is indicated, the level is increased until a response is obtained and then raised in 10-dB increments or until the audiometer’s limit is reached for the test frequency. The test results are plotted on a graph called an audiogram using symbols that indicate the ear tested and responses using earphones (air conduction) or oscillator (bone conduction).

**Air Conduction:**

Air conduction is tested first by starting at 1000 Hz and gradually decreasing the intensity 10 dB at a time until the patient no longer presses the button, indicating that the tone is no longer heard. The intensity is then increased 5 dB at a
time until the tone is heard again. This is repeated until the same response is achieved at a 50% response rate at the same hertz (Hz) level. The threshold is derived from the lowest decibel level at which the patient correctly identifies three out of six responses to a tone at that hertz level. The test is continued for each ear, testing the better ear first, with tones delivered at 1000 Hz, 2000 Hz, 4000 Hz, and 8000 Hz, and then again at 1000 Hz, 500 Hz, and 250 Hz to determine a second threshold. Results are recorded on a graph called an audiogram. Averaging the air conduction thresholds at the 500-Hz, 1000-Hz, and 2000-Hz levels reveals the degree of hearing loss and is called the pure tone average (PTA).

**Bone Conduction:**
Bone conduction testing is performed in a similar manner to air conduction testing. The raised and lowered tones are delivered as in air conduction using 250 Hz, 500 Hz, 1000 Hz, 2000 Hz, and 4000 Hz to determine the thresholds. An analysis of thresholds for air and bone conduction tones is done to determine the type of hearing loss (conductive, sensorineural, or mixed).

In children between 6 mo and 2 yr of age, minimal response levels can be determined by behavioral responses to test tone. In the child 2 yr and older, play audiometry that requires the child to perform a task or raise a hand in response to a specific tone is performed. In children 12 yr and older, the child is asked to follow directions in identifying objects; response to speech of specific intensities can be used to evaluate hearing loss that is affected by speech frequencies.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP who will discuss the results with the patient.
- Instruct the patient to resume usual activity, as directed by the HCP.
- Recognize anxiety related to test results, and be supportive of impaired activity related to hearing loss or perceived loss of independence. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Speech-Language-Hearing Association (www.asha.org) or for assistive technology at ABLEDATA (sponsored by the National Institute on Disability and Rehabilitation Research www.abledata.com).
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. As appropriate, instruct the patient in the use, cleaning, and storing of a hearing aid. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include evoked brain potential studies for hearing loss, otoscopy, spondee speech reception threshold, and tuning fork tests (Webber, Rinne).
- Refer to the table of tests associated with the Auditory System at the back of the book.
Barium Enema

SYNONYM/ACRONYM: Air-contrast barium enema, double-contrast barium enema, lower GI series, BE.

AREA OF APPLICATION: Colon.

CONTRAST: Barium sulfate, air, iodine mixture.

DESCRIPTION: This radiological examination of the colon, distal small bowel, and occasionally the appendix follows instillation of barium using a rectal tube inserted into the rectum or an existing ostomy. The patient must retain the barium while a series of radiographs are obtained. Visualization can be improved by using air or barium as the contrast medium (double-contrast study). A combination of x-ray and fluoroscopy techniques is used to complete the study. This test is especially useful in the evaluation of patients experiencing lower abdominal pain, changes in bowel habits, or the passage of stools containing blood or mucus, and for visualizing polyps, diverticula, and tumors. A barium enema may be therapeutic; it may reduce an obstruction caused by intussusception, or telescoping of the intestine. Barium enema should be performed before an upper gastrointestinal (GI) study or barium swallow.

RESULT:

Normal findings in:
• Normal size, filling, shape, position, and motility of the colon
• Normal filling of the appendix and terminal ileum

Abnormal findings in:
• Appendicitis
• Colorectal cancer
• Congenital anomalies
• Crohn’s disease
• Diverticular disease
• Fistulas
• Gastroenteritis
• Granulomatous colitis
• Hirschsprung’s disease
• Intussusception
• Perforation of the colon
• Polyps
• Sarcoma
• Sigmoid torsion
• Sigmoid volvulus
• Stenosis
• Tumors
• Ulcerative colitis

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with allergies to shell fish or iodinated dye, when iodinated contrast medium is used. The contrast medium, when used, may cause life-threatening allergic reaction. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
• Patients who are pregnant or suspected of being pregnant,

INDICATIONS:
• Determine the cause of rectal bleeding, blood, pus, or mucus in feces
• Evaluate suspected inflammatory process, congenital anomaly, motility disorder, or structural change
• Evaluate unexplained weight loss, anemia, or a change in bowel pattern
• Identify and locate benign or malignant polyps or tumors
unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.

- Patients with intestinal obstruction, acute ulcerative colitis, acute diverticulitis, megacolon, or suspected rupture of the colon.

Factors that may impair clear imaging:

- Gas or feces in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects within the examination field (e.g., jewelry, body rings)
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients
- Incorrect patient positioning, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Spasm of the colon, which can mimic the radiographic signs of cancer (Note: the use of intravenous glucagon minimizes spasm)
- Inability of the patient to tolerate introduction of, or retention of barium, air, or both in the bowel

Other considerations:

- Complications of the procedure may include hemorrhage and cardiac arrhythmias.
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area during the examination should wear badges to record their level of radiation exposure.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the colon.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast mediums.
- Obtain a history of the patient’s GI system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Verify that this procedure is performed before an upper GI study or barium swallow.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.
- Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is performed in a radiology department, by a HCP specializing in this procedure, with support staff, and takes approximately 30 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Patients with a colostomy will be ordered special preparations and colostomy irrigation.
Inform the patient that a laxative and cleansing enema may be needed the day before the procedure, with cleansing enemas on the morning of the procedure, depending on the institution’s policy.
Instruct the patient to remove all metallic objects from the area of the procedure.
Instruct the patient to eat a low-residue diet for several days before the procedure and to consume only clear liquids the evening before the test. The patient should fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility.

**INTRATEST:**
- Ensure the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations.
- Ensure the patient has removed all external metallic objects from the area to be examined.
- Assess for completion of bowel preparation according to the institution’s procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table and take an initial image.
- Instruct the patient to lie on their left side (Sims’ position). A rectal tube is inserted into the anus and an attached balloon is inflated after it is situated against the anal sphincter.
- Barium is instilled into the colon by gravity, and its movement through the colon is observed by fluoroscopy.
- For patients with a colostomy, an indwelling urinary catheter is inserted into the stoma and barium is administered.
- Images are taken with the patient in different positions to aid in the diagnosis.
- If a double-contrast barium enema has been ordered, air is then instilled in the intestine and additional images are taken.

The patient is helped to the bathroom to expel the barium, or placed on a bedpan if unable to ambulate.
After expulsion of the barium, a post-evacuation image is taken of the colon.

**POST-TEST:**
- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet, medications, or activity, as directed by the HCP.
- Instruct the patient to take a mild laxative and increase fluid intake (four 8-oz glasses) to aid in elimination of barium, unless contraindicated.
- Carefully monitor the patient for fatigue and fluid and electrolyte imbalance.
- Instruct the patient that stools will be white or light in color for 2 to 3 days. If the patient is unable to eliminate the barium, or if stools do not return to normal color, the patient should notify the HCP.
- Advise patients with a colostomy that tap water colostomy irrigation may aid in barium removal.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
- Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include cancer antigens, colonoscopy, colposcopy, CT abdomen, fecal analysis, MRI abdomen, PET pelvis, and proctosigmoidoscopy.
- Refer to the Gastrointestinal System table at the back of the book for related tests by body system.
**Barium Swallow**

**SYNONYM/ACRONYM:** Esophagram, video swallow, esophagus x-ray, swallowing function, esophography.

**AREA OF APPLICATION:** Esophagus.

**CONTRAST:** Barium sulfate, water-soluble iodinated contrast.

**DESCRIPTION:** This radiological examination of the esophagus evaluates motion and anatomic structures of the esophageal lumen by recording images of the lumen while the patient swallows a barium solution of milkshake consistency and chalky taste. The procedure uses fluoroscopic and cineradiographic techniques. The barium swallow is often performed as part of an upper gastrointestinal (GI) series or cardiac series and is indicated for patients with a history of dysphagia and gastric reflux. The study may identify reflux of the barium from the stomach back into the esophagus. Muscular abnormalities such as achalasia, as well as diffuse esophageal spasm, can be easily detected with this procedure.

**INDICATIONS:**
- Confirm the integrity of esophageal anastomoses in the postoperative patient
- Detect esophageal reflux, tracheoesophageal fistulas, and varices
- Determine the cause of dysphagia or heartburn
- Determine the type and location of foreign bodies within the pharynx and esophagus
- Evaluate suspected esophageal motility disorders
- Evaluate suspected polyps, strictures, Zenker’s diverticula, tumor, or inflammation

**RESULT:**

**Normal findings in:**
- Normal peristalsis through the esophagus into the stomach with normal size, filling, patency, and shape of the esophagus

**Abnormal findings in:**
- Achalasia
- Acute or chronic esophagitis
- Benign or malignant tumors
- Chalasia
- Diverticula
- Esophageal ulcers
- Esophageal varices
- Hiatal hernia
- Perforation of the esophagus
- Strictures or polyps

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

*This procedure is contraindicated for:*
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
- Patients with intestinal obstruction or suspected esophageal rupture,
unless water-soluble iodinated contrast medium is used
• Patients with suspected tracheoesophageal fistula, unless barium is used

Factors that may impair clear imaging:
• Metallic objects within the examination field
• Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure
• Incorrect patient positioning, which may produce poor visualization of the area to be examined
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
• Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
• A potential complication of a barium swallow is barium-induced fecal impaction.
• Ensure that the procedure is done after cholangiography and barium enema.
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses the esophagus.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
• Obtain a history of the patient’s GI system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Ensure that this procedure is performed before an upper GI study or video swallow.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Review the procedure with the patient and explain the need to swallow a barium contrast medium.
• Inform the patient that the procedure is performed in a radiology department by a HCP and takes approximately 15 to 30 min.
• Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• Instruct the patient to remove all external metallic objects from the area to be examined.
• Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility.

INTRATEST:
• Ensure the patient has complied with dietary and fluid restrictions for 8 hr prior to the procedure.
• Ensure the patient has removed all external metallic objects from the area to be examined.
Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate and follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Instruct the patient to stand in front of the x-ray fluoroscopy screen. Place the patient supine on the radiographic table if he or she is unable to stand.

An initial image is taken, and the patient is asked to swallow a barium solution with or without a straw.

Multiple images at different angles may be taken.

The patient may be asked to drink additional barium to complete the study. Swallowing the additional barium evaluates the passage of barium from the esophagus into the stomach.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.
- Carefully monitor the patient for fatigue and fluid and electrolyte imbalance.
- Instruct the patient to take a mild laxative and increase fluid intake (four 8-oz glasses) to aid in elimination of barium, unless contraindicated.
- Instruct the patient that stools will be white or light in color for 2 to 3 days. If the patient is unable to eliminate the barium, or if stools do not return to normal color, the patient should notify the requesting HCP.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include capsule endoscopy, chest x-ray, CT thoracic, endoscopy, esophageal manometry, gastroesophageal reflux scan, MRI chest, and thyroid scan.
- Refer to the Gastrointestinal System table at the back of the book for related tests by body system.

**SYNONYM/ACRONYM:** Conjugated/direct bilirubin, unconjugated/indirect bilirubin, delta bilirubin, TBil.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube or in a heparinized microtainer is also acceptable. Protect sample from direct light.

**REFERENCE VALUE:** (Method: Spectrophotometry) Total bilirubin levels in infants should decrease to adult levels by day 10 as the development of the hepatic
circulatory system matures. Values in breastfed infants may take longer to reach normal adult levels. Values in premature infants may initially be higher than in full-term infants and also take longer to decrease to normal levels.

**DESCRIPTION:** Bilirubin is a by-product of heme catabolism from aged red blood cells. Bilirubin is primarily produced in the liver, spleen, and bone marrow. Total bilirubin is the sum of unconjugated bilirubin, monoglucuronide and diglucuronide, conjugated bilirubin, and albumin-bound delta bilirubin. Unconjugated bilirubin is carried to the liver by albumin, where it becomes conjugated. In the small intestine, conjugated bilirubin converts to urobilinogen and then to urobilin. Urobilin is then excreted in the feces. Increases in bilirubin levels can result from prehepatic, hepatic, and/or posthepatic conditions, making fractionation useful in determining the cause of the increase in total bilirubin levels. Delta bilirubin has a longer half-life than the other bilirubin fractions and therefore remains elevated during convalescence after the other fractions have decreased to normal levels. When bilirubin concentration increases, the yellowish pigment deposits in skin and sclera. This increase in yellow pigmentation is termed jaundice or icterus. Bilirubin levels can also be checked using noninvasive methods. Defects in bilirubin excretion can be identified in a routine urinalysis. Hyperbilirubinemia in neonates can be reliably evaluated using transcutaneous measurement devices.

**INDICATIONS:**
- Assist in the differential diagnosis of obstructive jaundice
- Assist in the evaluation of liver and biliary disease
- Monitor the effects of drug reactions on liver function
- Monitor the effects of phototherapy on jaundiced newborns
- Monitor jaundice in newborn patients

**RESULT:**

**Increased in:**
- Prehepatic (hemolytic) jaundice (excessive amounts of heme released from RBC destruction are catabolized to bilirubin in concentrations that exceed the liver’s conjugation capacity and indirect bilirubin accumulates)
  Erythroblastosis fetalis
  Hematoma

Access additional resources at davisplus.fadavis.com
Hemolytic anemias
Pernicious anemia
Physiologic jaundice of the newborn
The post–blood transfusion period, when a number of units are rapidly infused or in the case of a delayed transfusion reaction
Red blood cell enzyme abnormalities (i.e., glucose-6-phosphate dehydrogenase, pyruvate kinase, spherocytosis)
• Hepatic jaundice—bilirubin conjugation failure
  Crigler-Najjar syndrome
• Hepatic jaundice—disturbance in bilirubin transport
  Dubin-Johnson syndrome (preconjugation transport failure)
  Gilbert’s syndrome (postconjugation transport failure)
• Hepatic jaundice—liver damage or necrosis interferes with excretion into bile ducts either by physical obstruction or drug inhibition and bilirubin accumulates
  Alcoholism
  Cholangitis
  Cholecystitis
  Cholestatic drug reactions
  Cirrhosis
  Hepatitis
  Hepatocellular damage
  Infectious mononucleosis
• Posthepatic jaundice
  Advanced tumors of the liver
  Biliary obstruction
• Other conditions
  Anorexia or starvation
  Premature or breastfed infants
  Hypothyroidism

Decreased in: N/A

CRITICAL VALUES:

Greater than 15 mg/dL
Note and immediately report to the health care provider (HCP) any critically increased values and related symptoms.

Sustained hyperbilirubinemia can result in brain damage. Kernicterus refers to the deposition of bilirubin in the basal ganglia and brainstem nuclei. There is no exact level of bilirubin that puts infants at risk for developing kernicterus. Symptoms of kernicterus in infants include lethargy, poor feeding, upward deviation of the eyes, and seizures. Intervention for infants may include early frequent feedings to stimulate gastrointestinal motility, phototherapy, and exchange transfusion.

INTERFERING FACTORS:

• Drugs that may increase bilirubin levels by causing cholestasis include amitriptyline, anabolic steroids, androgens, benzodiazepines, chlorothiazide, chlorpropamide, dapsone, erythromycin, estrogens, ethionamide, gold salts, imipramine, mercaptopurine, nitrofurans, oral contraceptives, penicillins, phenothiazines, progesterone, propoxyphene, sulfonamides, tamoxifen, and tolbutamide.

• Drugs that may increase bilirubin levels by causing hepatocellular damage include acetaminophen (toxic), acetylsalicylic acid, allopurinol, amiodarone, anabolic steroids, anticonvulsants, asparaginase, azithromycin, bromocriptine, captopril, cephalexin, chloramphenicol, clindamycin, clofibrate, danazol, enflurane, ethambutol, ethionamide, fenofibrate, fluconazole, fluoroquinolones, foscarnet, gentamicin, indomethacin, interferon, interleukin-2, levamisole, levodopa, lincomycin, low-molecular-weight heparin, methylprednisolone, monoamine oxidase inhibitors, naproxen, nifedipine, nitrofurans, oral contraceptives, probenecid, procarbazine, quinine, ranitidine, retinol, ritodrine, sulfonamides, tetracyclines, tobramycin, and verapamil.

• Drugs that may increase bilirubin levels by causing hemolysis include amphotericin B,
carbamazepine, carbutamide, cephaloridine, cephalothin, chlorpromazine, chlorpropamide, dinitrophenol, ibuprofen, insulin, isoniazid, levodopa, mefenamic acid, melphalan, methotrexate, methyldopa, penicillins, phenacetin, procainamide, quinidine, quinine, rifampin, stibophen, sulfonamides, and tolbutamide.

- Bilirubin is light sensitive. Therefore, the collection container should be suitably covered to protect the specimen from light between the time of collection and analysis.

**Nursing Implications and Procedure**

**Pretest:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess liver function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hepatobiliary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medication, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

**Intratest:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Protect the specimen from light and promptly transport the specimen to the laboratory for processing and analysis.

**Post-test:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- *Nutritional considerations:* Increased bilirubin levels may be associated with liver disease. Dietary recommendations may be indicated depending on the condition and severity of the condition. Currently, for example, there are no specific medications that can be given to cure hepatitis, but elimination of alcohol consumption and a diet optimized for convalescence are commonly included in the treatment plan. A high-calorie, high-protein, moderate-fat diet with a high fluid intake is often recommended for the patient with hepatitis. Treatment of cirrhosis is different because a low-protein diet may be in order if the patient’s liver has lost the ability to process the end products of protein...
metabolism. A diet of soft foods may also be required if esophageal varices have developed. Ammonia levels may be used to determine whether protein should be added to or reduced from the diet. Patients should be encouraged to eat simple carbohydrates and emulsified fats (as in homogenized milk or eggs), as opposed to complex carbohydrates (e.g., starch, fiber, and glycogen [animal carbohydrates]) and complex fats, which require additional bile to emulsify them so that they can be used. The cirrhotic patient should be carefully observed for the development of ascites, in which case fluid and electrolyte balance requires strict attention. The alcoholic patient should be encouraged to avoid alcohol and also to seek appropriate counseling for substance abuse.

Intervention for hyperbilirubinemia in the neonatal patient may include early frequent feedings (to stimulate gastrointestinal motility), phototherapy, and exchange transfusion.

Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ALT, albumin, ALP, ammonia, amylase, AMA/ASMA, α₁-antitrypsin/phenotyping, AST, biopsy liver, cholesterol, coagulation factor assays, complete blood count, cholangiography percutaneous transhepatic, cholangiography post-op, CT biliary tract and liver, copper, ERCP, GGT, hepatobiliary scan, hepatitis serologies, infectious mononucleosis screen, lipase, liver and spleen scan, protein total and fractions, PT/INR, US liver, and UA.

- See the Hepatobiliary System table at the end of the book for related tests by body system.

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Bladder tissue or cells.

**REFERENCE VALUE:** (Method: Macroscopic and microscopic examination of tissue) No abnormal tissue or cells.

**DESCRIPTION:** Biopsy is the excision of a sample of tissue that can be analyzed microscopically to determine cell morphology and the presence of tissue abnormalities. This test is used to assist in confirming the diagnosis of cancer when clinical symptoms or other diagnostic findings are suspicious.

---

**Biopsy, Bladder**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Bladder tissue or cells.

**REFERENCE VALUE:** (Method: Macroscopic and microscopic examination of tissue) No abnormal tissue or cells.
A urologist performs a biopsy of the bladder during cystoscopic examination. The procedure is usually carried out under general anesthesia. After the bladder is filled with saline for irrigation, the bladder and urethra are examined by direct and lighted visualization using a cystoscope. A sample of suspicious bladder tissue is then excised and examined macroscopically and microscopically to determine the presence of cell morphology and tissue abnormalities.

**INDICATIONS:**
- Assist in confirmation of malignant lesions of the bladder or ureter, especially if tumor is seen by radiological examination
- Assist in the evaluation of cases in which symptoms such as hematuria persist after previous treatment (e.g., removal of polyps or kidney stones)
- Monitor existing recurrent benign lesions for malignant changes

**RESULT:**
- **Positive findings in neoplasm of the bladder or ureter.**

**CRITICAL VALUES:**
It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

**INTERFERING FACTORS:**
- This test is contraindicated in patients with an acute infection of the bladder, urethra, or prostate.
- This procedure is contraindicated in patients with bleeding disorders.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to establish a diagnosis of bladder disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- Obtain a history of the patient’s genitourinary and immune systems, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals. Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Inform the patient that back pain and burning or pressure in the genital area may be experienced after the procedure. Prophylactic antibiotics may be administered before the procedure.

Access additional resources at davisplus.fadavis.com
procedure in certain cases. Address concerns about pain and explain that a general anesthesia will be administered prior to the biopsy. Explain that no pain will be experienced during the biopsy. Inform the patient that the biopsy is performed under sterile conditions by a HCP specializing in this procedure. The procedure usually takes about 30 to 45 min to complete.

- **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- Instruct the patient that nothing should be taken by mouth for 6 to 8 hr prior to a general anesthetic, or that only clear liquids may be taken for 8 hr prior to the procedure if local anesthesia is to be used. Protocols may vary from facility to facility.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 6 to 8 hr prior to the procedure.
- Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.
- Have emergency equipment readily available.
- Have the patient void before the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
- Assist the patient to a comfortable position, and direct the patient to breathe normally during the beginning of the general anesthetic.
- Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

**Cystoscopy:**

After administration of general anesthesia, place the patient in a lithotomy position on the examination table (with the feet up in stirrups). Drape the patient’s legs. Clean the external genitalia with a suitable antiseptic solution and drape the area with sterile towels.

- Once the cystoscope is inserted, the bladder is irrigated with saline. A tissue sample is removed using a cytology brush or biopsy forceps. Catheters may be used to obtain samples from the ureter.

**Open Biopsy:**

After administration of general anesthesia and surgical prep are completed, an incision is made, suspicious areas are located, and tissue samples are collected.

**General:**

- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- Place tissue samples in properly labeled specimen container containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume preoperative diet, as directed by the HCP.
- Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods.
- Monitor vital signs and neurologic status every 15 min for 1 hr, then
every 2 hr for 4 hr, and then as
ordered by the HCP. Monitor temper-
ature every 4 hr for 24 hr. Compare
with baseline values. Notify the
HCP if temperature is elevated.
Protocols may vary from facility to
facility.
Monitor fluid intake and output for
24 hr. Instruct the patient on intake
and output recording and
provide appropriate measuring
containers.
Encourage fluid intake of 3000 mL in
24 hr, unless contraindicated.
Observe for delayed allergic reactions,
such as rash, urticaria, tachycardia,
hyperpnea, hypertension, palpitations,
nausea, or vomiting.
Instruct the patient to immediately
report pain, chills, or fever. Assess for
infection, hemorrhage, or perforation of
the bladder.
Inform the patient that blood may
be seen in the urine after the first or
second postprocedural voiding.
Instruct the patient to report any
further changes in urinary pattern,
volume, or appearance.

Open Biopsy:
Observe the biopsy site for bleeding,
inflammation, or hematoma
formation.
Instruct the patient in the care and
assessment of the site. Instruct the
patient to report any redness, edema,
bleeding, or pain at the biopsy site.
Instruct the patient to keep the site
clean and change the dressing as
needed.

General:
Assess for nausea, pain, and
bladder spasms. Administer
antiemetic, analgesic, and antispas-
modic medications as needed and as
directed by the HCP.
Administer antibiotic therapy if ordered.
Remind the patient of the importance of
completing the entire course of
antibiotic therapy, even if signs
and symptoms disappear before
completion of therapy.
Recognize anxiety related to
test results. Discuss the implications
of abnormal test results on the
patient’s lifestyle. Provide teaching
and information regarding the clinical
implications of the test results, as
appropriate. Educate the patient
regarding access to counseling
services.
Reinforce information given by the
patient’s HCP regarding further
testing, treatment, or referral to
another HCP. Answer any questions or
address any concerns voiced by the
patient or family.
Instruct the patient in the use of any
ordered medications. Explain the
importance of adhering to the therapy
regimen. As appropriate, instruct
the patient in significant side effects
and systemic reactions associated
with the prescribed medication.
Encourage him or her to review
the Genitourinary and
Immune System tables at the back
of the book for related tests by body
system.

Related tests include calculus kidney
stone panel, cystometry, cystoscopy,
cystourethrography voiding, IVP,
KUB studies, MRI bladder, US
bladder, UA, and urine bladder cancer
markers.

Refer to the Genitourinary and
Immune System tables at the back
of the book for related tests by body
system.
Biopsy, Bone

SYNONYM/ACRONYM: N/A.

SPECIMEN: Bone tissue.

REFERENCE VALUE: (Method: Microscopic study of bone samples) No abnormal tissue or cells.

DESCRIPTION: Biopsy is the excision of a sample of tissue that can be analyzed microscopically to determine cell morphology and the presence of tissue abnormalities. This test is used to assist in confirming the diagnosis of cancer when clinical symptoms or x-rays are suspicious. After surgical incision to reveal the affected area, bone biopsy is obtained. An alternative collection method is needle biopsy, in which a plug of bone is removed using a special serrated needle.

INDICATIONS:
• Differentiation of a benign from a malignant bone lesion
• Radiographic evidence of a bone lesion

RESULT:
Abnormal findings in:
• Ewing’s sarcoma
• Multiple myeloma
• Osteoma
• Osteosarcoma

CRITICAL VALUES:
It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

INTERFERING FACTORS:
• This procedure is contraindicated in patients with bleeding disorders.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to establish a diagnosis of bone disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- Obtain a history of the patient’s immune and musculoskeletal systems, especially any bleeding disorders and other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and...
nutraceuticals. Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.

- Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the percutaneous biopsy; general anesthesia will be administered prior to the open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used, but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by a HCP specializing in this procedure. The surgical procedure usually takes about 30 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 20 min to complete.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- Explain that an IV line will be inserted to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.

**Open Biopsy:**
- Instruct the patient that nothing should be taken by mouth for 6 to 8 hr prior to a general anesthetic. Protocols may vary from facility to facility.

**Needle Biopsy:**
- Instruct the patient that nothing should be taken by mouth for at least 4 hr prior to the procedure to reduce the risk of nausea and vomiting. Protocols may vary from facility to facility.

**General:**
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**
- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 4 to 8 hr depending on the anesthetic chosen for the procedure.

- Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.

- Have emergency equipment readily available.

- Have the patient void before the procedure.

- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.

- Assist the patient to the desired position depending on the test site to be used, and direct the patient to breathe normally during the beginning of the general anesthetic. Instruct the patient to cooperate fully and to follow directions. For the patient undergoing local anesthesia, direct him or her to breathe normally and to avoid unnecessary movement during the procedure.

- Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

- After the administration of general or local anesthesia, shave and cleanse the site with an antiseptic solution, and drape the area with sterile towels.

**Open Biopsy:**
- After administration of general anesthesia and surgical prep are completed, an incision is made, suspicious area(s) are located, and tissue samples are collected.

**Needle Biopsy:**
- Instruct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes. A small incision is made and the biopsy needle is inserted to remove the specimen. Pressure is applied to the site for 3 to 5 min, then a sterile pressure dressing is applied.
**General:**
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- Place tissue samples in properly labeled specimen container containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume preoperative diet, as directed by the HCP.
- Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods.
- Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Observe the biopsy site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the site. Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to immediately report chills or fever. Instruct the patient to keep the site clean and change the dressing as needed.
- Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for removal of sutures, if indicated. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ALP, biopsy bone marrow, bone scan, calcium, complete blood count, cortisol, immunofixation electrophoresis, immunoglobulins A, G, and M, β₂-microglobulin, MRI musculoskeletal, PTH, phosphorus, total protein and fractions, UA, and vitamin D.
- See the Immune and Musculoskeletal System tables at the end of the book for related tests by body system.
**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Bone marrow aspirate, bone core biopsy, marrow and peripheral smears.

**REFERENCE VALUE:** (Method: Microscopic study of bone and bone marrow samples, flow cytometry) Reference ranges are subject to many variables, and therefore the laboratory should be consulted for their specific interpretation. Some generalities may be commented on regarding findings as follows:

- Ratio of marrow fat to cellular elements is related to age, with the amount of fat increasing with increasing age.
- Normal cellularity, cellular distribution, presence of megakaryocytes, and absence of fibrosis or tumor cells.
- The myeloid-to-erythrocyte ratio (M:E) is 2:1 to 4:1 in adults. It may be slightly higher in children.

**DESCRIPTION:** This test involves the removal of a small sample of bone marrow by aspiration, needle biopsy, or open surgical biopsy for a complete hemato logic analysis. The marrow is a suspension of blood, fat, and developing blood cells, which is evaluated for morphology and examined for all stages of maturation; iron stores; and M:E. Sudan black B and periodic acid–Schiff (PAS) stains can be performed for microscopic examination to differentiate the types of leukemia, although flow cytometry and cytogenetics have become more commonly used techniques for this purpose.

**INDICATIONS:**

- Determine marrow differential (proportion of the various types of cells present in the marrow) and M:E
- Evaluate abnormal results of complete blood count or white

Access additional resources at davisplus.fadavis.com
blood cell count with differential showing increased numbers of leukocyte precursors
• Evaluate hepatomegaly or splenomegaly
• Identify bone marrow hyperplasia or hypoplasia
• Identify infectious organisms present in the bone marrow (histoplasmosis, mycobacteria, CMV, parvovirus inclusions)
• Monitor effects of exposure to bone marrow depressants
• Monitor bone marrow response to chemotherapy or radiation therapy

RESULT:

**Increased Reticulocytes:**
- Compensated red blood cell (RBC) loss
- Response to vitamin B₁₂ therapy

**Decreased Reticulocytes:**
- Aplastic crisis of sickle cell anemia or hereditary spherocytosis

**Increased Leukocytes:**
(General associations include compensation for infectious process, leukemias, or leukemoid drug reactions)

**Decreased Leukocytes:**
(General associations include reduction in the marrow space as seen in metastatic neoplasm or myelofibrosis, lack of production of cells, lower production of cells as seen in the elderly, or following suppressive therapy such as chemo or radiation)

**Increased Neutrophils (Total):**
- Acute myeloblastic leukemia
- Myeloid (chronic) leukemias

**Decreased Neutrophils (Total):**
- Aplastic anemia
- Leukemias (monocytic and lymphoblastic)

**Increased Lymphocytes:**
- Aplastic anemia
- Lymphatic leukemia
- Lymphomas
- Lymphosarcoma
- Mononucleosis
- Viral infections

**Increased Plasma Cells:**
- Cancer
- Cirrhosis of the liver
- Connective tissue disorders
- Hypersensitivity reactions
- Infections
- Macroglobulinemia
- Ulcerative colitis

**Increased Megakaryocytes:**
- Hemorrhage
- Increasing age
- Infections
- Megakaryocytic myelosis
- Myeloid leukemia
- Pneumonia
- Polycythemia vera
- Thrombocytopenia

**Decreased Megakaryocytes:**
- Agranulocytosis
- Cirrhosis of the liver
- Pernicious aplastic anemia
- Radiation therapy
- Thrombocytopenic purpura

**Increased M:E:**
- Bone marrow failure
- Infections
- Leukemoid reactions
- Myeloid leukemia

**Decreased M:E:**
- Anemias
- Hepatic disease
- Polycythemia vera
- Posthemorrhagic hematopoiesis

**Increased Normoblasts:**
- Anemias
- Chronic blood loss
- Polycythemia vera

**Decreased Normoblasts:**
- Aplastic anemia
- Folic acid or vitamin B₁₂ deficiency
- Hemolytic anemia
Increased Eosinophils:
- Bone marrow cancer
- Lymphadenoma
- Myeloid leukemia

CRITICAL VALUES:
It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

INTERFERING FACTORS:
- Recent blood transfusions, iron therapy, or administration of cytotoxic agents may alter test results.
- **This procedure is contraindicated in patients with known bleeding disorders.**
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**Nursing Implications and Procedure**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to establish a diagnosis of bone marrow and immune system disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- Obtain a history of the patient’s hematopoietic and immune systems, especially any bleeding disorders and other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Note any recent procedures that can interfere with test results.

**Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals. Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.**

**Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the percutaneous biopsy; a general anesthesia will be administered prior to the open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used, but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by a HCP specializing in this procedure. The surgical procedure usually takes about 30 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 20 min to complete.**

**Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.**

**Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, or sedatives.**

**Instruct the patient that nothing should be taken by mouth for at least 4 hr prior to the procedure to reduce the risk of nausea and vomiting. Protocols may vary from facility to facility.**

**Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

**INTRATEST:**
- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 4 to 8 hr depending on the anesthetic chosen for the procedure.
Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.

- Have emergency equipment readily available.
- Have the patient void before the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
- Assist the patient to the desired position depending on the test site to be used. In young children, the most frequently chosen site is the proximal tibia. Vertebral bodies T10 through L4 are preferred in older children. In adults, the sternum or iliac crests are the preferred sites. Place the patient in the prone, sitting, or side-lying position for the vertebral bodies; the side-lying position for iliac crest or tibial sites; or the supine position for the sternum.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.

**Needle Aspiration:**
- The HCP will anesthetize the site with procaine or lidocaine, and then insert a needle with stylet into the marrow. The stylet is removed, a syringe attached, and a 0.5-mL aliquot of marrow withdrawn. The needle is removed, and pressure is applied to the site. The aspirate is applied to slides, and, when dry, a fixative is applied.

**Needle Biopsy:**
- Instruct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes.
- Local anesthetic is introduced deeply enough to include periosteum. A cutting biopsy needle is introduced through a small skin incision and bored into the marrow cavity. A core needle is introduced through the cutting needle, and a plug of marrow is removed. The needles are withdrawn, and the specimen is placed in a preservative solution. Pressure is applied to the site for 3 to 5 min, and then a pressure dressing is applied.

**General:**
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- Place tissue samples in properly labeled specimen container containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume preoperative diet, as directed by the HCP.
- Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Observe the biopsy site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the site. Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to immediately report chills or fever. Instruct the patient to keep the site clean and change the dressing as needed.
• Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
• Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
• Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
• Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for removal of sutures, if indicated. Answer any questions or address any concerns voiced by the patient or family.
• Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
• Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include biopsy lymph node, complete blood count, LAP, immunofixation electrophoresis, mediastinoscopy, and vitamin B₁₂.
- Refer to the Hematopoietic and Immune System tables at the back of the book for related tests by body system.

---

**Biopsy, Breast**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Breast tissue or cells.

**REFERENCE VALUE:** (Method: Macroscopic and microscopic examination of tissue for biopsy; cytochemical or immunohistochemical for estrogen and progesterone receptors, Ki67, PCNA, P53; flow cytometry for DNA ploidy and S-phase fraction; immunohistochemical or FISH for Her-2/neu. Fluorescence in situ hybridization (FISH) is a cytogenic technique that uses fluorescent labeled DNA probes to detect specific chromosome abnormalities.) Favorable findings:
- Biopsy: No abnormal cells or tissue
- DNA ploidy: Majority diploid cell population
- SPF: Low fraction of replicating cells in total cell population
- Her-2/neu, Ki67, PCNA, and P53: Negative to low percentage of stained cells
- Estrogen and Progesterone Receptors: High percentage of stained cells
DESCRIPTION: Breast cancer is the most common newly diagnosed cancer in American women. It is the second leading cause of cancer-related death. Biopsy is the excision of a sample of tissue that can be analyzed microscopically to determine cell morphology and the presence of tissue abnormalities. Fine needle and open biopsies of the breast have become more commonly ordered in recent years as increasing emphasis on early detection of breast cancer has become stronger. Breast biopsies are used to assist in the identification and prognosis of breast cancer. There are a number of tests that can be performed on breast tissue to assist in identification and management of breast cancer. *Estrogen and progesterone receptor assays (ER and PR)* are used to identify patients with a type of breast cancer that may be more responsive than other types of tumors to estrogen-deprivation (antiestrogen) therapy or removal of the ovaries. Patients with these types of tumors generally have a better prognosis. *DNA ploidy* testing by flow cytometry may also be performed on suspicious tissue. Cancer is the unchecked proliferation of tumor cells that contain abnormal amounts of DNA. The higher the grade of tumor cells, the more likely abnormal DNA will be detected. The *ploidy*, or number of chromosome sets in the nucleus, is an indication of the speed of cell replication and tumor growth. Cells synthesize DNA in the S phase of mitosis. *S-phase fraction (SPF)* is an indicator of the number of cells undergoing replication. Normal tissue will have a higher percentage of resting diploid cells or cells containing two chromosomes. Aneuploid cells contain multiple chromosomes. Genes on the chromosomes are coded to produce specific proteins. *Ki67 and proliferating cell nuclear antigen (PCNA)* are examples of proteins that can be measured to indicate the degree of cell proliferation in biopsied tissue. Overexpression of a protein called *human epidermal growth factor receptor 2* (HER-2/neu oncoprotein) is helpful in establishing histologic evidence of metastatic breast cancer. Metastatic breast cancer patients with high levels of HER-2/neu oncoprotein have a poor prognosis. They have rapid tumor progression, increased rate of recurrence, poor response to standard therapies, and a lower survival rate. Herceptin (trastuzumab) is indicated for treatment of HER-2/neu overexpression. *P53* is a suppressor protein that normally prevents cells with abnormal DNA from multiplying. Mutations in the P53 gene cause the loss of P53 functionality; the checkpoint is lost and cancerous cells are allowed to proliferate.

INDICATIONS:
- Evidence of breast lesion by palpation, mammography, or ultrasound
- Identify patients with breast or other types of cancer that may respond to hormone or antihormone therapy
• Monitor responsiveness to hormone or antihormone therapy
• Observable breast changes such as “peau d’orange” skin, scaly skin of the areola, drainage from the nipple, or ulceration of the skin

RESULT:
Positive findings in:
• Carcinoma of the breast
• Hormonal therapy (ER and PR)
• Receptor-positive tumors (ER and PR)

CRITICAL VALUES:
It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

INTERFERING FACTORS:
• This procedure is contra-indicated in patients with bleeding disorders.
• Antiestrogen preparations (e.g., tamoxifen) ingested 2 mo before tissue sampling will affect test results (ER and PR).
• Pretesting preservation of the tissue is method and test dependent. The testing laboratory should be consulted for proper instructions prior to the biopsy procedure.
• Failure to transport specimen to the laboratory immediately can result in degradation of tissue. Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results.
• Massive tumor necrosis or tumors with low cellular composition falsely decrease results.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the tests are used to establish a diagnosis of breast disease; in the presence of breast or other types of cancer the tests are used to assist in the prognosis and management of response to therapy.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
• Obtain a history of the patient’s immune and reproductive systems, especially any bleeding disorders and other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
• Note any recent procedures that can interfere with test results. Ensure that the patient has not received antiestrogen therapy within 2 mo of the test.
• Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals. Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
• Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the percutaneous biopsy; a general anesthesia will be administered prior to the
open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used, but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by a health care provider (HCP) specializing in this procedure. The surgical procedure usually takes about 20 to 30 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 15 min to complete.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.

Open Biopsy:
Instruct the patient that nothing should be taken by mouth for 6 to 8 hr prior to a general anesthetic. Protocols may vary from facility to facility.

Needle Biopsy:
Instruct the patient that nothing should be taken by mouth for at least 4 hr prior to the procedure to reduce the risk of nausea and vomiting. Protocols may vary from facility to facility.

General:
Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRAHEST:
Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 4 to 8 hr depending on the anesthetic chosen for the procedure. Ensure that the patient has not received antiestrogen therapy within 2 mo of the test.

Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.

Have emergency equipment readily available.

Have the patient void before the procedure.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location, especially left or right breast.

Assist the patient to the desired position depending on the test site to be used, and direct the patient to breathe normally during the beginning of the general anesthetic. Instruct the patient to cooperate fully and to follow directions. For the patient undergoing local anesthesia, direct him or her to breathe normally and to avoid unnecessary movement during the procedure.

Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

After the administration of general or local anesthesia, shave and cleanse the site with an antiseptic solution, and drape the area with sterile towels.

Open Biopsy:
After administration of general anesthesia and surgical prep are completed, an incision is made, suspicious area(s) are located, and tissue samples are collected.

Needle Biopsy:
Direct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes. Instruct the patient to take a deep breathe, exhale forcefully, and hold the breathe while the biopsy needle is inserted and rotated to obtain a core of breast tissue. Once the needle is removed, the patient may breathe. Pressure is applied to the site for 3 to 5 min, then a sterile pressure dressing is applied.

General:
Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
Place tissue samples in formalin solution. Label the specimen, indicating site location, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods.
- Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Observe the biopsy site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the site. Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to immediately report chills or fever. Instruct the patient to keep the site clean and change the dressing as needed.
- Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Cancer Society (http://www.cancer.org).
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for removal of sutures, if indicated. Instruct and educate the patient how to perform monthly breast self-examination and emphasize, as appropriate, the importance of having a mammogram performed annually. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage the patient to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include cancer antigens, mammogram, MRI breast, stereotactic biopsy breast, and US breast.
- Refer to the Immune and Reproductive System tables at the back of the book for related tests by body system.
Biopsy, Cervical

SYNONYM/ACRONYM: Cone Biopsy, LEEP.

SPECIMEN: Cervical tissue.

REFERENCE VALUE: (Method: Microscopic examination of tissue cells) No abnormal cells or tissue.

DESCRIPTION: Biopsy is the excision of a sample of tissue that can be analyzed microscopically to determine cell morphology and the presence of tissue abnormalities. The cervical biopsy is used to assist in confirmation of cancer when screening tests are positive. Cervical biopsy is obtained using an instrument that punches into the tissue and retrieves a tissue sample. Schiller's test entails applying an iodine solution to the cervix. Normal cells pick up the iodine and stain brown. Abnormal cells do not pick up any color. Punch biopsy results may indicate the need for a cone biopsy of the cervix. Cone biopsy is where a wedge shape of tissue is removed from the cervix by using a surgical knife, a carbon dioxide laser, or a loop electrosurgical excision procedure (LEEP). The LEEP procedure can be performed by placing the patient under a general anesthetic; by a regional anesthesia, such as a spinal or epidural; or by a cervical block, where a local anesthetic is injected into the cervix. The patient is given oral or IV pain medicine in conjunction with the local anesthetic when this method is used. Following colposcopy or cervical biopsy, LEEP can be used to treat abnormal tissue identified on biopsy.

INDICATIONS:
• Follow-up to abnormal Papanicolaou (Pap) smear, Schiller's test, or colposcopy
• Suspected cervical malignancy

RESULT:
Positive findings in:
• Carcinoma in situ
• Cervical dysplasia
• Cervical polyps

CRITICAL VALUES:
It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

INTERFERING FACTORS:
• The test is contraindicated in cases of acute pelvic inflammatory disease or bleeding disorders.
• This test should not be performed while the patient is menstruating.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
**BIOPSY, CERVICAL**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to establish a diagnosis of cervical disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, or anesthetics.
- Obtain a history of the patient’s immune and reproductive systems, especially any bleeding disorders and other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals. Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the percutaneous biopsy; general anesthesia will be administered prior to the open biopsy. Explain that no pain will be experienced during the test when general anesthesia is used, but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient the biopsy is performed under sterile conditions by a HCP specializing in this procedure. The surgical procedure usually takes about 20 to 30 min to complete, and sutures may be necessary to close the site.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.

**LEEP as an Outpatient Procedure:**
- Instruct the patient that nothing should be taken by mouth for at least 6 to 8 hr prior to a general anesthetic. Protocols may vary from facility to facility.

**LEEP in HCP’s Office:**
- Instruct the patient that nothing should be taken by mouth for at least 4 hr prior to the procedure to reduce the risk of nausea and vomiting. Protocols may vary from facility to facility.

**General:**
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**
- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 4 to 8 hr depending on the anesthetic chosen for the procedure.
- Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify HCP if patient anticoagulant therapy has not been withheld.
- Have emergency equipment readily available.
- Have the patient void before the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
- Have the patient remove clothes below the waist. Assist the patient into a
lithotomy position on a gynecologic exam table (with feet in stirrups). Drape the patient’s legs. Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local or general anesthetic and the procedure.

**Punch Biopsy:**
- A small round punch is rotated into the skin to the desired depth. The cylinder of skin is pulled upward with forceps and separated at its base with a scalpel or scissors. If needed, sutures are applied. A sterile dressing is applied over the site.
- Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
- After the administration of general or local anesthesia, shave and cleanse the site with an antiseptic solution, and drape the area with sterile towels.

**LEEP in the HCP’s Office:**
- A speculum is inserted into the vagina and is opened to gently spread apart the vagina for inspection of the cervix.
- The diseased tissue is removed along with a small amount of healthy tissue along the margins of the biopsy to ensure that no diseased tissue is left in the cervix after the procedure.

**LEEP as an Outpatient Procedure:**
- After administration of general anesthesia and surgical prep are completed, the procedure is carried out as noted above.

**General:**
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- Place tissue samples in properly labeled specimen container containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume preoperative diet, as directed by the HCP.
- Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods.
- Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to expect a gray-green vaginal discharge for several days, some vaginal bleeding may occur for up to 1 wk but should not be heavier than a normal menses, and some pelvic pain may occur. Instruct the patient to avoid strenuous activity for 8 to 24 hr, to avoid douching or intercourse for 2 wk or as instructed, and to report excessive bleeding, chills, fever, or any other unusual findings to the HCP.
- Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- Recognize anxiety related to test results and offer support. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the
patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage her to review corresponding literature provided by a pharmacist.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include chlamydia group antibodies, colposcopy, culture anal/genital, culture viral, Pap smear, and syphilis serology.
- See the Immune and Reproductive System tables at the back of the book for related tests by body system.

Biopsy, Chorionic Villus

SYNONYM/ACRONYM: N/A.

SPECIMEN: Chorionic villus tissue.

REFERENCE VALUE: (Method: Tissue culture) Normal karyotype.

DESCRIPTION: This test is used to detect fetal abnormalities caused by numerous genetic disorders. The advantage over amniocentesis is that it can be performed as early as the 8th wk of pregnancy, permitting earlier decisions regarding termination of pregnancy. However, unlike amniocentesis, this test will not detect neural tube defects.

INDICATIONS:
- Assist in the diagnosis of in utero metabolic disorders such as cystic fibrosis or other errors of lipid, carbohydrate, or amino acid metabolism
- Detect abnormalities in the fetus of women of advanced maternal age
- Determine fetal gender when the mother is a known carrier of a sex-linked abnormal gene that could be transmitted to male offspring, such as hemophilia or Duchenne’s muscular dystrophy
- Evaluate fetus in families with a history of genetic disorders, such as Down syndrome, Tay-Sachs disease, chromosome or enzyme anomalies, or inherited hemoglobinopathies

RESULT:

ABNORMAL KARYOTYPE: Numerous genetic disorders. Generally, the laboratory provides detailed interpretive information regarding the specific chromosome abnormality detected.

CRITICAL VALUES:
It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

Access additional resources at davisplus.fadavis.com
INTERFERING FACTORS:

- The test is contraindicated in the patient with a history of or in the presence of incompetent cervix.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to establish a diagnosis of in utero genetic disorders.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- Obtain a history of the patient’s reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Include any family history of genetic disorders such as cystic fibrosis, Duchenne’s muscular dystrophy, hemophilia, sickle cell anemia, Tay-Sachs disease, thalassemia, and trisomy 21.
- Obtain maternal Rh type. If Rh-negative, check for prior sensitization.
- Record the date of the last menstrual period and determine that the pregnancy is in the first trimester between the 10th and 12th wk.
- Obtain a history of intravenous drug use, high-risk sexual activity, or occupational exposure.
- Obtain a history of intravenous drug use, high-risk sexual activity, or occupational exposure.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Warn the patient that normal results do not guarantee a normal fetus. Assure the patient that precautions to avoid injury to the fetus will be taken by locating the fetus with ultrasound. Address concerns about pain related to the procedure. Explain that, during the transabdominal procedure, any discomfort with a needle biopsy will be minimized with local anesthetics. Explain that, during the transvaginal procedure, some cramping may be experienced as the catheter is guided through the cervix. Encourage relaxation and controlled breathing during the procedure to aid in reducing any mild discomfort. Inform the patient that specimen collection is performed by a HCP specializing in this procedure and usually takes approximately 10 to 15 min to complete.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.
- Instruct the patient to drink a glass of water about 30 min prior to testing so that the bladder is full. This elevates the uterus higher in the pelvis. The patient should not void before the procedure.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRAVENT:**

- Ensure that the patient has a full bladder before the procedure.
- Have emergency equipment readily available.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
- Have the patient remove clothes below the waist. Transabdominal: Assist the patient into a supine position on the exam table with abdomen exposed. Drape the patient’s legs, leaving abdomen exposed. Transvaginal: Assist the patient into a lithotomy position on a gynecologic examination table (with feet in stirrups). Drape the patient’s legs. Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- Record maternal and fetal baseline vital signs, and continue to monitor throughout the procedure. Monitor for
uterine contractions. Monitor fetal vital signs using ultrasound. Protocols may vary from facility to facility.

After the administration of local anesthesia, shave and cleanse the site with an antiseptic solution, and drape the area with sterile towels.

**Transabdominal Biopsy:**
- Assess the position of the amniotic fluid, fetus, and placenta using ultrasound.
- A needle is inserted through the abdomen into the uterus, avoiding contact with the fetus. A syringe is connected to the needle and the specimen of chorionic villus cells is withdrawn from the uteroplacental area. Pressure is applied to the site for 3 to 5 min, then a sterile pressure dressing is applied.

**Transvaginal Biopsy:**
- Assess the position of the fetus and placenta using ultrasound.
- A speculum is inserted into the vagina and is opened to gently spread apart the vagina for inspection of the cervix. The cervix is cleansed with a swab of antiseptic solution.
- A catheter is inserted through the cervix into the uterus, avoiding contact with the fetus. A syringe is connected to the catheter and the specimen of chorionic villus cells is withdrawn from the uteroplacental area.

**General:**
- Monitor the patient for complications related to the procedure (e.g., premature labor, allergic reaction, anaphylaxis).
- Place tissue samples in formalin solution. Label the specimen, indicating site location, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- After the procedure, the patient is placed in the left side-lying position, and both maternal and fetal vital signs are monitored for at least 30 min. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Observe the biopsy site for bleeding, inflammation, or hematoma formation.

Instruct the patient in the care and assessment of the site. Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to keep the site clean and change the dressing as needed.

Instruct the patient to expect mild cramping, leakage of small amount of amniotic fluid, and vaginal spotting for up to 2 days following the procedure. Instruct the patient to report moderate to severe abdominal pain or cramps, increased or prolonged leaking of amniotic fluid from vagina or abdominal needle site, vaginal bleeding that is heavier than spotting, and either chills or fever.

Administer Rh(D) immune globulin (RhoGAM IM or Rhophylac IM or IV) to maternal Rh-negative patients to prevent maternal Rh sensitization should the fetus be Rh-positive.

Administer mild analgesic and antibiotic therapy as ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Encourage family to seek counseling if concerned with pregnancy termination or to seek genetic counseling if chromosomal abnormality is determined. Decisions regarding elective abortion should take place in the presence of both parents. Provide a nonjudgmental, nonthreatening atmosphere for a discussion during which risks of delivering a developmentally challenged infant are discussed with options (termination of pregnancy or adoption). It is also important to discuss problems the mother and father may experience (guilt, depression, anger) if fetal abnormalities are detected.

Reinforce information given by the patient’s HCP regarding further testing.
Biopsy, Intestinal

SYNONYM/ACRONYM: N/A.

SPECIMEN: Intestinal tissue or cells.

REFERENCE VALUE: (Method: Macroscopic and microscopic examination of tissue) No abnormal tissue or cells.

DESCRIPTION: Intestinal biopsy is the excision of a tissue sample from the small intestine for microscopic analysis to determine cell morphology and the presence of tissue abnormalities. This test assists in confirming the diagnosis of cancer or intestinal disorders. Biopsy specimen is usually obtained during endoscopic examination.

INDICATIONS:
- Assist in the diagnosis of various intestinal disorders, such as lactose and other enzyme deficiencies, celiac disease, and parasitic infections
- Confirm suspected intestinal malignancy
- Confirm suspicious findings during endoscopic visualization of the intestinal wall

RESULT:
Abnormal findings in:
- Cancer
- Celiac disease
- Lactose deficiency
- Parasitic infestation
- Tropical sprue

CRITICAL VALUES:
It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.
INTERFERING FACTORS:
• Barium swallow within 48 hr of small intestine biopsy affects results.
• This procedure is contra-indicated in patients with bleeding disorders and aortic arch aneurysm.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➧ Inform the patient that the test is used to establish a diagnosis of intestinal disease.
➧ Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
➧ Obtain a history of the patient’s gastrointestinal and immune systems, any bleeding disorders, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
➧ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
➧ Note any recent procedures that can interfere with test results.
➧ Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals. Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
➧ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Address concerns about pain and explain that a sedative may be administered to promote relaxation during the procedure. Inform the patient that the procedure is performed by a HCP specializing in this procedure and usually takes about 60 min to complete.
➧ Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
➧ Explain that an IV line will be inserted to allow infusion of IV fluids, anesthetics, and analgesics.
➧ Explain that a clear liquid diet is to be consumed 1 day prior to the procedure. Then food and fluids are restricted for 6 to 8 hr before the test. Protocols may vary from facility to facility.
➧ Provide the patient with a gown, robe, and foot coverings and instruct him or her to void prior to the procedure.
➧ Instruct the patient to remove dentures, jewelry (including watches), hairpins, credit cards, and other metallic objects. Inform the HCP if the patient has any crowns or caps on the teeth.
➧ Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:
➧ Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 6 to 8 hr prior to the procedure if general anesthesia will be used.
➧ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.
➧ Have emergency equipment readily available.
➧ Observe standard precautions and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
➧ Assist the patient into a semireclining position. Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

**Esophagogastroduodenoscopy (EGD) Biopsy:**
- A local anesthetic is sprayed into the throat. A protective tooth guard and a bite block may be placed in the mouth.
- The flexible endoscope is passed into and through the mouth, and the patient is asked to swallow. Once the endoscope passes into the esophagus, assist the patient into the left lateral position. A suction device is used to drain saliva.
- The esophagus, stomach, and duodenum are visually examined as the endoscope passes through each section. A biopsy specimen can be taken from any suspicious sites.
- Tissue samples are obtained by inserting a cytology brush or biopsy forceps through the endoscope.
- When the examination and tissue removal are complete, the endoscope and suction device are withdrawn and the tooth guard and bite block are removed.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- Place tissue samples in formalin solution. Label the specimen, indicating site location, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet, as directed by the HCP. Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods.
- Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Instruct the patient to report any chest pain, upper abdominal pain, pain on swallowing, difficulty breathing, or expectoration of blood. Report these to the HCP immediately.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Administer mild analgesic and antibiotic therapy as ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include albumin, antibodies gliadin, calcium, cancer antigens, capsule endoscopy, colonoscopy, D-xylose tolerance, fecal analysis, fecal fat, folic acid, iron/TIBC, LTT, ova and parasite, potassium, PT/INR, sodium, vitamin B12, and vitamin D.
- Refer to the Gastrointestinal and Immune System tables at the back of the book for related tests by body system.
Biopsy, Kidney

**SYNONYM/ACRONYM:** Renal biopsy.

**SPECIMEN:** Kidney tissue or cells.

**REFERENCE VALUE:** (Method: Macroscopic and microscopic examination of tissue) No abnormal cells or tissue.

**DESCRIPTION:** Kidney or renal biopsy is the excision of a tissue sample from the kidney for microscopic analysis to determine cell morphology and the presence of tissue abnormalities. This test assists in confirming a diagnosis of cancer found on x-ray or ultrasound or to diagnose certain inflammatory or immunological conditions. Biopsy specimen is usually obtained either percutaneously or after surgical incision.

**INDICATIONS:**
- Assist in confirming suspected renal malignancy
- Assist in the diagnosis of the cause of renal disease
- Determine extent of involvement in systemic lupus erythematosus or other immunological disorders
- Monitor progression of nephrotic syndrome
- Monitor renal function after transplantation
- Immunological rejection of transplanted kidney
- Nephrotic syndrome
- Pyelonephritis
- Renal venous thrombosis

**CRITICAL VALUES:**
It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

**INTERFERING FACTORS:**
- This procedure is contraindicated in bleeding disorders, advanced renal disease, uncontrolled hypertension, or solitary kidney (except transplanted kidney).
- Obesity and severe spinal deformity can make percutaneous biopsy impossible.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**RESULT:**
**Positive findings in:**
- Acute and chronic poststreptococcal glomerulonephritis
- Amyloidosis infiltration
- Cancer
- Disseminated lupus erythematosus
- Goodpasture’s syndrome

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to establish a diagnosis of kidney disease.
Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.

Obtain a history of the patient’s genitourinary and immune system, especially any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Note any recent procedures that can interfere with test results.

Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals. Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.

Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the percutaneous biopsy; a general anesthesia will be administered prior to the open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used, but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by a HCP specializing in this procedure. The surgical procedure usually takes about 60 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 40 min to complete.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. Explain that an IV line will be inserted to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.

Open Biopsy:

Instruct the patient that nothing should be taken by mouth for 6 to 8 hr prior to a general anesthetic. Protocols may vary from facility to facility.

 Needle Biopsy:

Instruct the patient that nothing should be taken by mouth for at least 4 hr prior to the procedure to reduce the risk of nausea and vomiting. Protocols may vary from facility to facility.

General:

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 4 to 8 hr depending on the anesthetic chosen for the procedure.

Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.

Have emergency equipment readily available.

Have the patient void before the procedure.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location, especially left or right kidney.

Assist the patient to the desired position depending on the test site to be used, and direct the patient to breathe normally during the beginning of the general anesthetic. Instruct the patient to cooperate fully and to follow directions. Direct the patient to avoid unnecessary movement.

Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

After the administration of general or local anesthesia, shave and
cleanse the site with an antiseptic solution, and drape the area with sterile towels.

**Open Biopsy:**
- After administration of general anesthesia and surgical prep are completed, an incision is made, suspicious area(s) are located, and tissue samples are collected.

**Needle Biopsy:**
- A sandbag may be placed under the abdomen to aid in moving the kidneys to the desired position. Direct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes. Instruct the patient to take a deep breathe, exhale forcefully, and hold the breathe while the biopsy needle is inserted and rotated to obtain a core of renal tissue. Once the needle is removed, the patient may breathe. Pressure is applied to the site for 5 to 20 min, then a sterile pressure dressing is applied.

**General:**
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- Place tissue samples in formalin solution. Label the specimen, indicating site location, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods.
- Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Observe the biopsy site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the site. Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to immediately report chills or fever. Instruct the patient to keep the site clean and change the dressing as needed. Instruct the patient to immediately report symptoms such as backache, flank pain, shoulder pain, lightheadedness, burning on urination, hematuria, chills, or fever, which may indicate the presence of infection, hemorrhage, or inadvertent puncture of other internal organs. Observe the patient for other signs of distress, including hypotension and tachycardia.
- Inform the patient that blood may be seen in the urine after the first or second postprocedural voiding.
- Monitor fluid intake and output for 24 hr. Instruct the patient on intake and output recording and provide appropriate measuring containers.
- Instruct the patient to report any changes in urinary pattern or volume or any unusual appearance of the urine. If urinary volume is less than 200 mL in the first 8 hr, encourage the patient to increase fluid intake unless contraindicated by another medical condition.
- Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for removal of sutures, if
indicated. Answer any questions or address any concerns voiced by the patient or family.

- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include albumin, aldosterone, angiography renal, antibodies, anti-glomerular basement membrane, $\beta_2$-microglobulin, BUN, CT renal, creatinine, creatinine clearance, cytology urine, cystoscopy, IVP, KUB studies, osmolality, PTH, potassium, protein, renin, renogram, sodium, US kidney, and UA.
- Refer to the Genitourinary and Immune System tables at the back of the book for related tests by body system.

---

**Biopsy, Liver**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Liver tissue or cells.

**REFERENCE VALUE:** (Method: Macroscopic and microscopic examination of tissue)

No abnormal cells or tissue.

**DESCRIPTION:** Liver biopsy is the excision of a tissue sample from the liver for microscopic analysis to determine cell morphology and the presence of tissue abnormalities. This test is used to assist in confirming a diagnosis of cancer or certain disorders of the hepatic parenchyma. Biopsy specimen is usually obtained either percutaneously or after surgical incision.

**RESULT:**

- Assist in diagnosing the cause of persistently elevated liver enzymes, hepatomegaly, or jaundice

**Positive findings in:**

- Benign tumor
- Cancer
- Cholesterol ester storage disease
- Cirrhosis
- Galactosemia
- Hemochromatosis
- Hepatic involvement with systemic lupus erythematosus, sarcoidosis, or amyloidosis
- Hepatitis
- Parasitic infestations (e.g., amebiasis, malaria, visceral larva migrans)

**INDICATIONS:**

- Assist in confirming suspected hepatic malignancy
- Assist in confirming suspected hepatic parenchymal disease
Reye’s syndrome
Wilson’s disease

CRITICAL VALUES:
It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

INTERFERING FACTORS:
• This procedure is contraindicated in patients with bleeding disorders, suspected vascular tumor of the liver, ascites that may obscure proper insertion site for needle biopsy, subdiaphragmatic or right hemotoracic infection, or biliary tract infection.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➧ Inform the patient that the test is used to establish a diagnosis of liver disease.
➧ Obtain a history of the patient’s complaints, especially fatigue and pain related to inflammation and swelling of the liver. Include a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
➧ Obtain a history of the patient’s hepatobiliary and immune system, especially any bleeding disorders and other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
➧ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
➧ Note any recent procedures that can interfere with test results.
➧ Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals. Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
➧ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the percutaneous biopsy; a general anesthesia will be administered prior to the open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used, but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by a HCP specializing in this procedure. The surgical procedure usually takes about 90 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 15 min to complete.
➧ Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
➧ Explain that an IV line will be inserted to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.

Open Biopsy:
➧ Instruct the patient that nothing should be taken by mouth for 6 to 8 hr prior to a general anesthetic. Protocols may vary from facility to facility.

Needle Biopsy:
➧ Instruct the patient that nothing should be taken by mouth for at least 4 hr prior to the procedure to reduce the risk of nausea and vomiting. Protocols may vary from facility to facility.

General:
➧ Make sure a written and informed consent has been signed prior to the
Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 4 to 8 hr depending on the anesthetic chosen for the procedure.

Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.

Have emergency equipment readily available.

Have the patient void before the procedure.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.

Assist the patient to the desired position depending on the test site to be used and direct the patient to breathe normally during the beginning of the general anesthetic. Instruct the patient to cooperate fully and to follow directions. For the patient undergoing local anesthesia, direct him or her to breathe normally and to avoid unnecessary movement during the procedure. Instruct the patient to avoid coughing or straining, as this may increase intra-abdominal pressure.

Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

After the administration of general or local anesthesia, shave and cleanse the site with an antiseptic solution, and drape the area with sterile towels.

After administration of general anesthesia and surgical prep are completed, an incision is made, suspicious area(s) are located, and tissue samples are collected.

Direct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes. Instruct the patient to take a deep breathe, exhale forcefully, and hold the breathe while the biopsy needle is inserted and rotated to obtain a core of liver tissue. Once the needle is removed, the patient may breathe. Pressure is applied to the site for 3 to 5 min, then a sterile pressure dressing is applied.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).

Place tissue samples in formalin solution. Label the specimen, indicating site location, and promptly transport the specimen to the laboratory for processing and analysis.

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods.

Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Observe the biopsy site for bleeding, inflammation, or hematoma formation.

Instruct the patient in the care and assessment of the site. Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to immediately report chills or fever. Instruct the patient to keep the site clean and change the dressing as needed. Instruct the patient to immediately report any pleuritic pain, persistent right shoulder pain, or abdominal pain.

Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as
directed by the health care practitioner.
- Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for removal of sutures, if indicated. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHYS:**
- Related tests include ALT, albumin, ALP, ammonia, amylase, AMA/ASMA, α₁-antitrypsin/phenotyping, AST, bilirubin, cholesterol, coagulation factors, complete blood count, copper, GGT, hepatitis antigens and antibodies, infectious mononucleosis screen, laparoscopy abdominal, lipase, liver and spleen scan, MRI liver, PT/INR, radiofrequency ablation liver, UA, and US liver.
- Refer to the Hepatobiliary and Immune System tables at the end of the book for related tests by body system.

---

**Biopsy, Lung**

**SYNONYM/ACRONYM:** Transbronchial lung biopsy, open lung biopsy.

**SPECIMEN:** Lung tissue or cells.

**REFERENCE VALUE:** (Method: Macroscopic and microscopic examination of tissue)
No abnormal tissue or cells; no growth in culture.

**DESCRIPTION:** A biopsy of the lung is performed to obtain lung tissue for examination of pathologic features. The specimen can be obtained transbronchially or by open lung biopsy. In a transbronchial biopsy, forceps pass through the bronchoscope to obtain the specimen. In a transbronchial needle aspiration biopsy, a needle passes through a bronchoscope to obtain the

Access additional resources at davisplus.fadavis.com
specimen. In a transcatheter bronchial brushing, a brush is inserted through the bronchoscope. In an open lung biopsy, the chest is opened and a small thoracic incision is made to remove tissue from the chest wall. Lung biopsies are used to differentiate between infection and other sources of disease indicated by initial radiology studies, computed tomography scans, or sputum analysis. Specimens are cultured to detect pathogenic organisms or directly examined for the presence of malignant cells.

**INDICATIONS:**
- Assist in the diagnosis of lung cancer
- Assist in the diagnosis of fibrosis and degenerative or inflammatory diseases of the lung
- Assist in the diagnosis of sarcoidosis

**RESULT:**
**Abnormal findings in:**
- Amyloidosis
- Cancer
- Granulomas
- Infections caused by *Blastomyces, Histoplasma, Legionella* spp., and *Pneumocystis jiroveci* (formerly *carinii*)
- Sarcoidosis
- Systemic lupus erythematosus
- Tuberculosis

**CRITICAL VALUES:**
- Shortness of breathe, cyanosis, or rapid pulse during the procedure must be reported immediately.
- Any postprocedural decrease in breathe sounds noted at the biopsy site should be reported immediately.

It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

**INTERFERING FACTORS:**
- Conditions such as vascular anomalies of the lung, bleeding abnormalities, or pulmonary hypertension may increase the risk of bleeding.
- Conditions such as bullae or cysts and respiratory insufficiency increase the risk of pneumothorax.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to establish a diagnosis of lung disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- Obtain a history of the patient’s immune and respiratory systems, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals. Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- Review the procedure with the patient.
- Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct that prophylactic antibiotics may be
administered prior to the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the transbronchial needle aspiration biopsy; a general anesthesia will be administered prior to the open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used, but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Atropine is usually given before bronchoscopy examinations to reduce bronchial secretions and prevent vagally induced bradycardia. Meperidine (Demerol) or morphine may be given as a sedative. Lidocaine is sprayed in the patient’s throat to reduce discomfort caused by the presence of the tube. Inform the patient that the biopsy is performed under sterile conditions by a HCP specializing in this procedure. The surgical procedure usually takes about 30 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 15 to 30 min to complete.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- Instruct the patient that nothing should be taken by mouth for 6 to 8 hr prior to a general anesthetic. Protocols may vary from facility to facility.
- Have the patient void before the procedure.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 6 to 8 hr prior to the procedure.
- Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.
- Have emergency equipment readily available. Keep resuscitation equipment on hand in the case of respiratory impairment or laryngospasm after the procedure.
- Avoid using morphine sulfate in those with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location, especially left or right lung.
- Have patient remove dentures, contact lenses, eyeglasses, and jewelry. Notify the HCP if the patient has permanent crowns on teeth. Have the patient remove clothing and change into a gown for the procedure.
- Assist the patient to a comfortable position, and direct the patient to breathe normally during the beginning of the general anesthesia. Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- Record baseline vital signs and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
- After the administration of general or local anesthesia, shave and cleanse the site with an antiseptic solution, and drape the area with sterile towels.

**Open Biopsy:**

The patient is prepared for thoracotomy under general anesthesia in the operating room. Tissue specimens are collected from suspicious sites. Place specimen from needle aspiration or brushing on clean glass microscope slides. Place tissue or aspirate specimens in appropriate sterile container for culture or appropriate fixative container for histological studies. Carefully observe the patient for any signs of respiratory distress during the procedure.
A chest tube is inserted after the procedure.

**Needle Biopsy:**
Instruct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes. Assist patient to a sitting position with arms on a pillow over a bed table. Instruct patient to avoid coughing during the procedure. The needle is inserted through the posterior chest wall and into the intercostal space. The needle is rotated to obtain the sample and then withdrawn. Pressure is applied to the site with a Vaseline gauze, and a pressure dressing is applied over the Vaseline gauze.

**Bronchoscopy:**
Provide mouth care to reduce oral bacterial flora.

After administration of general anesthesia, position the patient in a supine position with the neck hyperextended. If local anesthesia is used, the patient is seated while the tongue and oropharynx are sprayed and swabbed with anesthetic. Provide an emesis basin for the increased saliva and encourage the patient to spit out the saliva because the gag reflex may be impaired. When loss of sensation is adequate, the patient is placed in a supine or side-lying position. The fiberoptic scope can be introduced through the nose, the mouth, an endotracheal tube, a tracheostomy tube, or a rigid bronchoscope. Most common insertion is through the nose. Patients with copious secretions or massive hemoptysis, or in whom airway complications are more likely, may be intubated before the bronchoscopy. Additional local anesthetic is applied through the scope as it approaches the vocal cords and the carina, eliminating reflexes in these sensitive areas. The fiberoptic approach allows visualization of airway segments without having to move the patient’s head through various positions.

After visual inspection of the lungs, tissue samples are collected from suspicious sites by bronchial brush or biopsy forceps to be used for cytologic and microbiologic studies.

After the procedure, the bronchoscope is removed. Patients who had local anesthesia are placed in a semi-Fowler’s position to recover.

**General:**
Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).

Place tissue samples in properly labeled specimen containers containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient. Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods. Inform the patient that he or she may experience some throat soreness and hoarseness. Instruct patient to treat throat discomfort with lozenges and warm gargles when the gag reflex returns.

Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

Emergency resuscitation equipment should be readily available if the vocal cords become spastic after intubation. Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperventilation, hypertension, palpitations, nausea, or vomiting.

Observe the biopsy site for bleeding, inflammation, or hematoma formation.

Observe the patient for hemoptysis, difficulty breathing, cough, air hunger, excessive coughing, pain, or absent breathe sounds over the affected area. Report to HCP. Monitor chest tube patency and drainage after a thoracotomy.

Evaluate the patient for symptoms indicating the development of
pneumothorax, such as dyspnea, tachypnea, anxiety, decreased breathing sounds, or restlessness. A chest x-ray may be ordered to check for the presence of this complication.

Evaluate the patient for symptoms of empyema, such as fever, tachycardia, malaise, or elevated white blood cell count.

Observe the patient’s sputum for blood if a biopsy was taken, because large amounts of blood may indicate the development of a problem; a small amount of streaking is expected. Evaluate the patient for signs of bleeding, such as tachycardia, hypotension, or restlessness.

Instruct the patient in the care and assessment of the biopsy site. Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to keep the site clean and change the dressing as needed.

Instruct the patient to remain in a semi-Fowler’s position after bronchoscopy or fine needle aspiration to maximize ventilation. Semi-Fowler’s position is a semisitting position with the knees flexed and supported by pillows on the bed or examination table. Instruct the patient to stay in bed lying on the affected side for at least 2 hr with a pillow or rolled towel under the site to prevent bleeding. The patient will also need to remain on bed rest for 24 hr.

Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.

Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient to use lozenges or gargle for throat discomfort. Inform the patient of smoking cessation programs as appropriate. Malnutrition is commonly seen in patients with severe respiratory disease for numerous reasons, including fatigue, lack of appetite, and gastrointestinal distress. Adequate intake of vitamins A and C are also important to prevent pulmonary infection and to decrease the extent of lung tissue damage. The importance of following the prescribed diet should be stressed to the patient/caregiver. Educate the patient regarding access to counseling services, as appropriate. Answer any questions or address any concerns voiced by the patient or family.

Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include arterial/alveolar oxygen ratio, antibodies, anti-glomerular basement membrane, blood gases, bronchoscopy, chest x-ray, complete blood count, CT thoracic, culture sputum, cytology sputum, gallium scan, gram/acid fast stain, lung perfusion scan, lung ventilation scan, MRI chest, mediastinoscopy, pleural fluid analysis, PFT, and TB skin tests.

Refer to the Immune and Respiratory System tables at the back of the book for related tests by body system.
Biopsy, Lymph Node

SYNONYM/ACRONYM: N/A

SPECIMEN: Lymph node tissue or cells.

REFERENCE VALUE: (Method: Macroscopic and microscopic examination of tissue)
No abnormal tissue or cells.

DESCRIPTION: Lymph node biopsy is the excision of a tissue sample from one or more lymph nodes for microscopic analysis to determine cell morphology and the presence of tissue abnormalities. This test assists in confirming a diagnosis of cancer, diagnosing disorders causing systemic illness, or determining the stage of metastatic cancer. A biopsy specimen is usually obtained either by needle biopsy or after surgical incision. Biopsies are most commonly performed on the following types of lymph nodes: cervical nodes, which drain the face and scalp; axillary nodes, which drain the arms, breasts, and upper chest; and inguinal nodes, which drain the legs, external genitalia, and lower abdominal wall.

INDICATIONS:
• Assist in confirming suspected fungal or parasitic infections of the lymphatics
• Assist in confirming suspected malignant involvement of the lymphatics
• Determine the stage of metastatic cancer
• Differentiate between benign and malignant disorders that may cause lymph node enlargement
• Evaluate persistent enlargement of one or more lymph nodes for unknown reasons

RESULT:
Abnormal findings in:
• Chancroid
• Fungal infection (e.g., cat scratch disease)
• Immunodeficiency
• Infectious mononucleosis
• Lymph involvement of systemic diseases (e.g., systemic lupus erythematosus, sarcoidosis)
• Lymphangitis
• Lymphogranuloma venereum
• Malignancy (e.g., lymphomas, leukemias)
• Metastatic disease
• Parasitic infestation (e.g., pneumoconiosis)

CRITICAL VALUES:
It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

INTERFERING FACTORS:
• This procedure is contraindicated in patients with bleeding disorders.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
BIOPSY, LYMPH NODE

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to establish a diagnosis of lymph node disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- Obtain a history of the patient’s immune and musculoskeletal systems, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals. Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the percutaneous biopsy; a general anesthesia will be administered prior to the open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used, but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by a HCP, specializing in this procedure, with support staff. The surgical procedure usually takes about 30 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 15 min to complete. 

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. Explain that an IV line will be inserted to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.

Open Biopsy:
- Instruct the patient that nothing should be taken by mouth for 6 to 8 hr prior to a general anesthetic. Protocols may vary from facility to facility.

Needle Biopsy:
- Instruct the patient that nothing should be taken by mouth for at least 4 hr prior to the procedure to reduce the risk of nausea and vomiting. Protocols may vary from facility to facility.

General:
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:
- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 4 to 8 hr depending on the anesthetic chosen for the procedure.
- Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.
- Have emergency equipment readily available.
- Have the patient void before the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
- Assist the patient to the desired position depending on the test site to be used and direct the patient to breathe normally during the beginning of the general anesthetic. Instruct the patient to cooperate fully and to follow
directions. For the patient undergoing local anesthesia, direct him or her to breathe normally and to avoid unnecessary movement during the procedure.
Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
After the administration of general or local anesthesia, shave and cleanse the site with an antiseptic solution, and drape the area with sterile towels.

**Open Biopsy:**
After administration of general anesthesia and surgical prep are completed, an incision is made, suspicious area(s) are located, and tissue samples are collected.

**Needle Biopsy:**
Instruct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes. The node is grasped with sterile gloved fingers, and a needle (with attached syringe) is inserted directly into the node. The node is aspirated to collect the specimen. Pressure is applied to the site for 3 to 5 min, then a sterile dressing is applied.

**General:**
Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
Place tissue samples in formalin solution. Label the specimen, indicating site location, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods.
Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
Observe the biopsy site for bleeding, inflammation, or hematoma formation.
Instruct the patient in the care and assessment of the site. Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to immediately report chills or fever. Instruct the patient to keep the site clean and change the dressing as needed.
Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for removal of sutures, if indicated. Answer any questions or address any concerns voiced by the patient or family.
Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in
Biopsy, Muscle

SYNONYM/ACRONYM: N/A

SPECIMEN: Muscle tissue or cells.

REFERENCE VALUE: (Method: Macroscopic and microscopic examination of tissue)
No abnormal tissue or cells.

DESCRIPTION: Muscle biopsy is the excision of a muscle tissue sample for microscopic analysis to determine cell morphology and the presence of tissue abnormalities. This test is used to confirm a diagnosis of neuropathy or myopathy and to diagnose parasitic infestation. A biopsy specimen is usually obtained from the deltoid or gastrocnemius muscle after a surgical incision.

INDICATIONS:
• Assist in confirming suspected fungal infection or parasitic infestation of the muscle
• Assist in diagnosing the cause of neuropathy or myopathy
• Assist in the diagnosis of Duchenne’s muscular dystrophy

RESULT:
Abnormal findings in:
• Alcoholic myopathy
• Amyotrophic lateral sclerosis
• Duchenne’s muscular dystrophy
• Fungal infection
• Myasthenia gravis
• Myotonia congenita
• Parasitic infestation
• Polymyalgia rheumatica
• Polymyositis

CRITICAL VALUES:
It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

INTERFERING FACTORS:
• If electromyography is performed before muscle biopsy, residual
inflammation may lead to false-positive biopsy results.
- This procedure is contraindicated in patients with bleeding disorders.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to establish a diagnosis of musculoskeletal disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- Obtain a history of the patient’s immune and musculoskeletal systems, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals. Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the percutaneous biopsy; a general anesthesia will be administered prior to the open biopsy. Explain that no pain will be experienced during the test when general anesthesia is used, but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by a HCP specializing in this procedure. The surgical procedure usually takes about 20 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 15 min to complete.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, or sedatives.
- Instruct the patient that nothing should be taken by mouth for at least 4 hr prior to the procedure to reduce the risk of nausea and vomiting. Protocols may vary from facility to facility.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**
- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 4 hr prior to the procedure.
- Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.
- Have emergency equipment readily available.
- Have the patient void before the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
- Assist the patient to a comfortable position: a supine position (for deltoid biopsy) or prone position (for
gastrocnemius biopsy). Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.

Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

After the administration of general or local anesthesia, shave and cleanse the site with an antiseptic solution, and drape the area with sterile towels.

**Open Biopsy:**
- Assess baseline neurologic status.
- Instruct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes.
- After infiltration of the site with local anesthetic, a small incision is made through the dermis, exposing the muscle. A small area of muscle is excised and removed with forceps. The area is then closed with sutures or similar material, and a sterile dressing is applied.

**Needle Biopsy:**
- Instruct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes.
- After infiltration of the site with local anesthetic, a cutting biopsy needle is introduced through a small skin incision and bored into the muscle. A core needle is introduced through the cutting needle, and a plug of muscle is removed. The needles are withdrawn, and the specimen is placed in a preservative solution. Pressure is applied to the site for 3 to 5 min, and then a pressure dressing is applied.

**General:**
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- Place tissue samples in properly labeled specimen container containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume preoperative diet, as directed by the HCP.
- Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Observe the biopsy site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the site. Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to immediately report chills or fever. Instruct the patient to keep the site clean and change the dressing as needed.
- Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for removal of sutures, if indicated. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy.
regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include AChR, aldolase, ANA, antibody Jo-1, antithyroglobulin antibodies, CK and isoenzymes, EMG, ENG, myoglobin, and RF.
- Refer to the Immune and Musculo-skeletal System tables at the back of the book for related tests by body system.

**Biopsy, Prostate**

**SYNONYM/ACRONYM:** N/A

**SPECIMEN:** Prostate tissue.

**REFERENCE VALUE:** (Method: Microscopic examination of tissue cells) No abnormal cells or tissue.

**DESCRIPTION:** Biopsy of the prostate gland is performed to identify cancerous cells, especially if serum prostate-specific antigen is increased.

**INDICATIONS:**
- Evaluate prostatic hypertrophy of unknown etiology
- Investigate suspected cancer of the prostate

**RESULT:** Positive findings in prostate cancer.

### Gleason Grading

<table>
<thead>
<tr>
<th>Grade</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Simple round glands, closely packed rounded masses with well-defined edges. Closely resemble normal prostate tissue.</td>
</tr>
<tr>
<td>2</td>
<td>Simple round glands, loosely packed in vague, rounded masses with loosely packed edges. Closely resemble normal prostate tissue.</td>
</tr>
<tr>
<td>3</td>
<td>Small, very small, or medium-sized single glands of irregular shape and spacing with poorly defined infiltrating edges.</td>
</tr>
<tr>
<td>4</td>
<td>Small, medium, or large glands fused into cords, chains, or ragged infiltrating masses.</td>
</tr>
<tr>
<td>5</td>
<td>No glandular differentiation, solid sheets, cords, single cells with central necrosis.</td>
</tr>
</tbody>
</table>
The Gleason Score is the sum of 2 grades assigned by the pathologist during microscopic examination of the biopsy samples. The score ranges from 1–10 with 10 being the worst. The first number assigned is the primary grade (1–5), which indicates where the cancer is the most prominent. The second number is the secondary grade (1–5), which indicates where the cancer is next most prominent. It is important to have the breakdown in grading as well as the total score. For example, Patient A’s Gleason Score is $4 + 3 = 7$ and Patient B’s Gleason Score is $3 + 4 = 7$. Even though both patients have the same Gleason Score, Patient B has a slightly better prognosis because the primary area is graded a 3.

</table>

**CRITICAL VALUES:**

It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

**INTERFERING FACTORS:**

- This procedure is contraindicated in patients with bleeding disorders.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- The various sampling approaches have individual drawbacks that should be considered: transurethral sampling does not always ensure that malignant cells will be included in the specimen, whereas transrectal sampling carries the risk of perforating the rectum and creating a channel through which malignant cells can seed normal tissue.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to establish a diagnosis of prostate disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- Obtain a history of the patient’s genitourinary and immune systems, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications including anticoagulants,
Aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals. Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.

Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the percutaneous biopsy; a general anesthesia will be administered prior to the open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used, but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by a HCP, with support staff, specializing in this procedure. The surgical procedure usually takes about 30 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 20 min to complete.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.

Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.

Instruct the patient that nothing should be taken by mouth for 6 to 8 hr prior to a general anesthetic. Protocols may vary from facility to facility.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 6 to 8 hr prior to the procedure.

- Have emergency equipment readily available.
- Have the patient void before the procedure. Administer enemas if ordered.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
- Assist the patient to a comfortable position, and direct the patient to breathe normally during the beginning of the general anesthesia.
- Cleanse the biopsy site with an antiseptic solution, and drape the area with sterile towels.
- Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

**Transurethral Approach:**

After administration of general anesthesia, position the patient on a urologic exam table with the feet in stirrups. The endoscope is inserted into the urethra. The tissue is excised with a cutting loop and is placed in formalin solution.

**Transrectal Approach:**

After administration of general anesthesia, position the patient in the Sims’ position. A rectal examination is performed to locate suspicious nodules. A biopsy needle guide is placed at the biopsy site, and the biopsy needle is inserted through the needle guide. The cells are aspirated, the needle is withdrawn, and the sample is placed in formalin solution.

**Perineal Approach:**

After administration of general anesthesia, position the patient in the lithotomy position. Clean the perineum with an antiseptic solution, and protect the biopsy site with sterile drapes. A small incision is made and the sample is removed by needle biopsy or biopsy punch and placed in formalin solution.

**General:**

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
Apply digital pressure to the biopsy site. If there is no bleeding after the perineal approach, place a sterile dressing on the biopsy site. Immediately notify the HCP if there is significant bleeding.

Place tissue samples in properly labeled specimen containers containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods.

Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

Monitor fluid intake and output for 24 hr. Instruct the patient on intake and output recording and provide appropriate measuring containers.

Encourage fluid intake of 3000 mL, unless contraindicated.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Observe the perineal approach biopsy site for bleeding, inflammation, or hematoma formation. Instruct the patient to keep the site clean and change the dressing as needed.

Instruct the patient to immediately report pain, chills, or fever. Assess for infection, hemorrhage, or perforation of the urethra or rectum.

Inform the patient that blood may be seen in the urine after the first or second postprocedural voiding.

Instruct the patient to report any further changes in urinary pattern, volume, or appearance.

Assess for nausea, pain, and bladder spasms. Administer antiemetic, analgesic, and antispasmodic medications as needed and as directed by the HCP.

Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the National Cancer Institute (www.cancer.gov).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Counsel the patient, as appropriate, that sexual dysfunction related to altered body function, drugs, or radiation may occur. Educate the patient regarding access to counseling services, as appropriate. Answer any questions or address any concerns voiced by the patient or family.

Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him to review corresponding literature provided by a pharmacist.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include cystoscopy, cystourethrography voiding, PAP, PSA, retrograde ureteropyelography, semen analysis, and US prostate.

Refer to the Genitourinary and Immune System tables at the back of the book for related tests by body system.
**Biopsy, Skin**

**SYNONYM/ACRONYM:** N/A

**SPECIMEN:** Skin tissue or cells.

**REFERENCE VALUE:** (Method: Macroscopic and microscopic examination of tissue)
No abnormal tissue or cells.

**DESCRIPTION:** Skin biopsy is the excision of a tissue sample from suspicious skin lesions. The microscopic analysis can determine cell morphology and the presence of tissue abnormalities. This test assists in confirming the diagnosis of malignant or benign skin lesions. A skin biopsy can be obtained by any of these four ways: curettage, shaving, excision, or punch. A Tzanck (Tsanck) smear may be prepared from vesicles (blisters) present on the skin. Skin cells in the vesicles can be evaluated microscopically to indicate the presence of certain viruses, especially herpes, that cause cells to become enlarged and otherwise abnormal in appearance.

**INDICATIONS:**
- Assist in the diagnosis of keratoses, warts, moles, keloids, fibromas, cysts, or inflamed lesions
- Assist in the diagnosis of inflammatory process of the skin, especially herpes infection
- Assist in the diagnosis of skin cancer
- Evaluate suspicious skin lesions

**RESULT:**

*Abnormal findings in:*
- Basal cell carcinoma
- Cysts
- Dermatitis
- Dermatofibroma
- Keloids
- Malignant melanoma
- Neurofibroma
- Pemphigus
- Pigmented nevi
- Seborrheic keratosis
- Skin involvement in systemic lupus erythematosus, discoid lupus erythematosus, and scleroderma
- Squamous cell carcinoma
- Viral infection (herpes, varicella)
- Warts

**CRITICAL VALUES:**

It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

**INTERFERING FACTORS:**
- This procedure is contraindicated in patients with bleeding disorders.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
Inform the patient that the test is used to establish a diagnosis of skin disease.

Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.

Obtain a history of the patient’s immune and musculoskeletal systems, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Note any recent procedures that can interfere with test results.

Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals. Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.

Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the punch biopsy; a general anesthesia will be administered prior to the open biopsy. Explain that no pain will be experienced during the test when general anesthesia is used, but that any discomfort with a punch biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient the biopsy is performed under sterile conditions by a HCP, with support staff, specializing in this procedure. The surgical procedure usually takes about 30 min to complete, and sutures may be necessary to close the site. A punch biopsy usually takes about 20 min to complete.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Ensure that the patient has complied with dietary restrictions, if ordered by the HCP.

Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.

Have emergency equipment readily available.

Have the patient void before the procedure.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.

Assist the patient to the desired position depending on the test site to be used, and direct the patient to breathe normally during the local anesthetic and the procedure. Instruct the patient to cooperate fully, follow directions and avoid unnecessary movement.

Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

After the administration of general or local anesthesia, shave and cleanse the site with an antiseptic solution, and drape the area with sterile towels.

Curettage: The skin is scraped with a curette to obtain specimen.

Shaving or excision: A scalpel is used to remove a portion of the lesion that protrudes above the epidermis. If the lesion is to be excised, the incision is

Access additional resources at davisplus.fadavis.com
made as wide and as deep as needed to ensure that the entire lesion is removed. Bleeding is controlled with external pressure to the site. Large wounds are closed with sutures. An adhesive bandage is applied when excision is complete.

**Punch biopsy:** A small, round punch about 4 to 6 mm in diameter is rotated into the skin to the desired depth. The cylinder of skin is pulled upward with forceps and separated at its base with a scalpel or scissors. If needed, sutures are applied. A sterile dressing is applied over the site.

- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- Place tissue samples in properly labeled specimen container containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume preoperative diet, as directed by the HCP.
- Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods.
- Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Observe the biopsy site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the site. Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to immediately report chills or fever. Instruct the patient to keep the site clean and change the dressing as needed.
- Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for the removal of sutures, if indicated. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include allergen-specific IgE, ANA, culture skin, eosinophil count, ESR, and IgE.
- Refer to the Immune and Musculo-skeletal System tables at the back of the book for related tests by body system.
Biopsy, Thyroid

SYNONYM/ACRONYM: N/A

SPECIMEN: Thyroid gland tissue or cells.

REFERENCE VALUE: (Method: Macroscopic and microscopic examination of tissue)
No abnormal tissue or cells.

DESCRIPTION: Thyroid biopsy is the excision of a tissue sample for microscopic analysis to determine cell morphology and the presence of tissue abnormalities. This test assists in confirming a diagnosis of cancer or determining the cause of persistent thyroid symptoms. A biopsy specimen can be obtained by needle aspiration or by surgical excision.

INDICATIONS:
• Assist in the diagnosis of thyroid cancer or benign cysts or tumors
• Determine the cause of inflammatory thyroid disease
• Determine the cause of hyperthyroidism
• Evaluate enlargement of the thyroid gland

RESULT:
Positive findings in:
• Benign thyroid cyst
• Granulomatous thyroiditis
• Hashimoto’s thyroiditis
• Nontoxic nodular goiter
• Thyroid cancer

CRITICAL VALUES:
It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

INTERFERING FACTORS:
• This procedure is contraindicated in patients with bleeding disorders.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to establish a diagnosis of thyroid disease.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
• Obtain a history of the patient’s endocrine and immune systems, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Record the date of the last menstrual period and determine possibility of pregnancy in perimenopausal women.
• Note any recent procedures that can interfere with test results.

Access additional resources at davisplus.fadavis.com
Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals. Such products be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.

Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the percutaneous biopsy; general anesthesia will be administered prior to the open biopsy. Explain that no pain will be experienced during the test when general anesthesia is used, but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by a HCP, with support staff, specializing in this procedure. The surgical procedure usually takes about 30 min to complete, and that sutures may be necessary to close the site. A needle biopsy usually takes about 15 min to complete.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.

**Open Biopsy:**
- Instruct the patient that nothing should be taken by mouth for 6 to 8 hr prior to a general anesthetic. Protocols may vary from facility to facility.

**Needle Biopsy:**
- Instruct the patient that nothing should be taken by mouth for at least 4 hr prior to the procedure to reduce the risk of nausea and vomiting. Protocols may vary from facility to facility.
- Have the patient void before the procedure.

**General:**
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**
- Ensure that the patient has complied with dietary restrictions; assure food has been restricted for at least 4 to 8 hr depending on the anesthetic chosen for the procedure.
- Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependant on the type of anticoagulant. Notify HCP if patient anticoagulant therapy has not been withheld.
- Have emergency equipment readily available.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
- Assist the patient to the desired position depending on the test site to be used and direct the patient to breathe normally during the beginning of the general anesthetic. Instruct the patient to cooperate fully and to follow directions. For the patient undergoing local anesthesia, direct him or her to breathe normally and to avoid unnecessary movement during the procedure.
- Record baseline vital signs and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
- After the administration of general or local anesthesia, direct him or her to breathe normally and to avoid unnecessary movement during the procedure.
- After administration of general anesthesia and surgical prep is completed, an incision is made, suspicious area(s) are located, and tissue samples are collected.
**Needle Biopsy:**
- Direct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes. Instruct the patient to take a deep breathe, exhale forcefully, and hold the breathe while the biopsy needle is inserted and rotated to obtain a core of breast tissue. Once the needle is removed, the patient may breathe. Pressure is applied to the site for 3 to 5 min, then a sterile pressure dressing is applied.

**General:**
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- Place tissue samples in properly labeled specimen container containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP who will discuss the results with the patient.
- Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods.
- Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Notify the HCP if elevated temperature. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Observe the biopsy site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the site. Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to immediately report chills or fever. Instruct the patient to keep the site clean and change the dressing as needed.
- Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- Recognize anxiety related to test. Discuss the implications of the abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for removal of sutures, if indicated. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include antibodies, antithyroglobulin, calcitonin and stimulation tests, parathyroid scan, radioactive iodine uptake, thyroid-binding inhibitory immunoglobulin, thyroid scan, TSH, free thyroxine, and US thyroid.
- Refer to the Endocrine and Immune System tables at the back of the book for related tests by body system.
Bladder Cancer Markers, Urine

SYNONYM/ACRONYM: Nuclear Matrix Protein (NMP) 22, Bard BTA, cytogenic marker for bladder cancer.

SPECIMEN: Urine (5 mL), unpreserved random specimen collected in a clean plastic collection container for NMP22 and Bard BTA), Urine (30 mL), first void specimen collected in fixative specific for FISH testing.

REFERENCE VALUE: (Method: Enzyme immunoassay for NMP22, immunochromatographic for Bard BTA, Fluorescence in situ Hybridization (FISH) for cytogenic marker)
- **NMP22**: Negative: Less than 6 units/mL, Borderline: 6–10 units/mL, Positive: Greater than 10 units/mL
- **Bard BTA**: Negative
- **Cytogenic Marker**: Negative

DESCRIPTION: Cystoscopy is still considered the gold standard for detection of bladder cancer, but other noninvasive tests are being developed, including several urine assays approved by the Food and Drug Administration. Compared to cytologic studies, these assays are believed to be more sensitive but less specific for detecting transitional cell carcinoma. FISH is a cytogenic technique that uses fluorescent-labeled DNA probes to detect specific chromosome abnormalities. The FISH bladder cancer assay specifically detects the presence of aneuploidy for chromosomes 3, 7, 17, and absence of the 9p21 loci; findings associated with transitional cell cancer of the bladder.

**NMP22**: Nuclear matrix proteins (NMPs) are involved in the regulation and expression of various genes. The NMP identified as NuMA is abundant in bladder tumor cells. The dying tumor cells release the soluble NMP into the urine. This assay is quantitative.

Bladder tumor antigen (BTA): A human complement factor H-related protein (hCFHrp) is thought to be produced by bladder tumor cells as protection from the body’s natural immune response. BTA is released from tumor cells into the urine. This assay is qualitative.

INDICATIONS:
- Detection of bladder carcinoma
- Management of recurrent bladder cancer

RESULT: Increased in bladder carcinoma.

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- **NMP22**: Any condition that results in inflammation of the bladder or urinary tract may cause falsely elevated values.
- **Bard BTA**: Recent surgery, biopsy, or other trauma to the bladder or urinary tract may cause falsely elevated values. Bacterial overgrowth from active urinary...
tract infection, renal or bladder calculi, gross contamination from blood, and positive leukocyte dipstick may also cause false-positive results.

- **Cytogenic marker:** Incorrect fixative, gross contamination from blood, bacterial overgrowth from active urinary tract infection, inadequate number of bladder cells in specimen.

## Nursing Implications and Procedure

### Pretest:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to diagnose bladder cancer.
- Obtain a history of the patient’s complaints, including a list of known allergens.
- Obtain a history of the patient’s genitourinary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain and explain that there should be no discomfort during the procedure. Inform the patient that specimen collection takes approximately 5 min, depending on the cooperation and ability of the patient.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

### Intratest:
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.
- Obtain urine specimen in a clean plastic collection container. Promptly transport the specimen to the laboratory for processing and analysis.

### Post-test:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

### Related Monographs:
- Related tests include biopsy bladder, cytology urine, cystoscopy, and US bladder.
- Refer to the Genitourinary and Immune System tables at the back of the book for related tests by body system.
**SYNONYM/ACRONYM:** Mielke bleeding time, Simplate bleeding time, Template bleeding time, Surgicutt, Ivy bleeding time.

**SPECIMEN:** Whole blood.

**REFERENCE VALUE:** (Method: Timed observation of incision)
- **Template:** 2.5 to 10 min
- **Ivy:** 2 to 7 min

There are slight differences in the disposable devices used to make the incision. Although the Mielke or Template bleeding time is believed to offer greater standardization to a fairly subjective procedure, both methods are thought to be of equal sensitivity and reproducibility.

**RESULT:**
This test does not predict excessive bleeding during a surgical procedure.

**Prolonged in:**
- Bernard-Soulier syndrome *(rare hereditary condition in which platelet glycoprotein GP1b is deficient and platelet aggregation is decreased)*
- Fibrinogen disorders *(fibrinogen helps platelets link together)*
- Glanzmann’s thrombasthenia *(rare hereditary condition in which platelet glycoprotein IIb/IIIa is deficient and platelet aggregation is decreased)*
- Hereditary telangiectasia *(fragile blood vessels do not permit adequate constriction to stop bleeding)*
- Liver disease *(any condition that affects the production of coagulation proteins will affect bleeding time)*
- Some myeloproliferative disorders *(where production of platelets is decreased)*
- Renal disease *(abnormal platelet function)*
- Thrombocytopenia *(insufficient platelets to stop bleeding)*
- von Willebrand’s disease *(deficiency of von Willebrand factor, necessary for normal platelet adhesion)*

**Decreased in:** N/A

**CRITICAL VALUES:**
Greater than 14 min

Note and immediately report to the health care practitioner (HCP) any critically increased values and related symptoms.

Find and print out the full monograph at DavisPlus (davisplus.fadavis.com, keyword Van Leeuwen).
SYNONYM/ACRONYM: Arterial blood gases (ABGs), venous blood gases, capillary blood gases, cord blood gases.

SPECIMEN: Whole blood. Specimen volume and collection container may vary with collection method. See Intratest section for specific collection instructions. Specimen should be tightly capped and transported in an ice slurry.

REFERENCE VALUE: (Method: Selective electrodes for pH, pCO₂ and pO₂)

**DESCRIPTION:** Blood gas analysis is used to evaluate respiratory function and provide a measure for determining acid-base balance. Respiratory, renal, and cardiovascular system functions are integrated in order to maintain normal acid-base balance. Therefore, respiratory or metabolic disorders may cause abnormal blood gas findings. The blood gas measurements commonly reported are pH, partial pressure of carbon dioxide in the blood (pCO₂), partial pressure of oxygen in the blood (pO₂), bicarbonate (HCO₃⁻), O₂ saturation, and base excess (BE) or base deficit (BD). pH reflects the number of free hydrogen ions (H⁺) in the body. A pH less than 7.35 indicates acidosis. A pH greater than 7.45 indicates alkalosis. Changes in the ratio of free hydrogen ions to bicarbonate will result in a compensatory response from the lungs or kidneys to restore proper acid-base balance.

pCO₂ is an important indicator of ventilation. The level of pCO₂ is controlled primarily by the lungs and is referred to as the respiratory component of acid-base balance. The main buffer system in the body is the...
bicarbonate–carbonic acid system. Bicarbonate is an important alkaline ion that participates along with other anions such as hemoglobin, proteins, and phosphates to neutralize acids. For the body to maintain proper balance, there must be a ratio of 20 parts bicarbonate to one part carbonic acid (20:1). Carbonic acid level is indirectly measured by pCO₂. Bicarbonate level is indirectly measured by the total carbon dioxide content (tCO₂). The carbonic acid level is not measured directly, but can be estimated because it is 3% of the pCO₂. Bicarbonate can also be calculated from these numbers once the carbonic acid value has been obtained because of the 20:1 ratio. For example, if the pCO₂ were 40, the carbonic acid would be calculated as (3% × 40) or 1.2, and the HCO₃⁻ would be calculated as (20 × 1.2) or 24.

The main acid in the acid-base system is carbonic acid. It is the metabolic or nonrespiratory component of the acid-base system and is controlled by the kidney. Bicarbonate levels can either be measured directly or estimated from the tCO₂ in the blood. BE/BD reflects the number of anions available in the blood to help buffer changes in pH. A BD (negative BE) indicates metabolic acidosis, whereas a positive BE indicates metabolic alkalosis.

Extremes in acidosis are generally more life threatening than alkalosis. Acidosis can develop either very quickly (e.g., cardiac arrest) or over a longer period of time (e.g., renal failure). Infants can develop acidosis very quickly if they are not kept warm and given enough calories. Children with diabetes tend to go into acidosis more quickly than do adults who have been dealing with the disease over a longer period of time. In many cases a venous or capillary specimen is satisfactory to obtain the necessary information regarding acid-base balance without subjecting the patient to an arterial puncture with its associated risks.

As seen in the table of reference ranges, pO₂ is lower in infants than in children and adults owing to the respective level of maturation of the lungs at birth. pO₂ tends to trail off after age 30, decreasing by approximately 3 to 5 mm Hg per decade as the organs age and begin to lose elasticity. There is a formula that can be used to approximate the relationship between age and pO₂:

\[
pO₂ = 104 - (age \times 0.27)
\]

Like carbon dioxide, oxygen is carried in the body in a dissolved and combined (oxyhemoglobin) form. Oxygen content is the sum of the dissolved and combined oxygen. The oxygen-carrying capacity of the blood indicates how much oxygen could be carried if all the hemoglobin were saturated with oxygen. Percent oxygen saturation is \([oxyhemoglobin concentration \div (oxyhemoglobin concentration + deoxyhemoglobin concentration)] \times 100.\)

Testing on specimens other than arterial blood is often ordered when oxygen measurements are not needed or when the information regarding oxygen can be obtained by noninvasive techniques such as pulse oximetry. Capillary blood is satisfactory for most purposes for pH and
pCO₂: the use of capillary pO₂ is limited to the exclusion of hypoxia. Measurements involving oxygen are usually not useful when performed on venous samples; arterial blood is required to accurately measure pO₂ and oxygen saturation. There is considerable evidence that prolonged exposure to high levels of oxygen can result in injury, such as retinopathy of prematurity in infants or the drying of airways in any patient. Monitoring pO₂ from blood gases is especially appropriate under such circumstances.

**INDICATIONS:** This group of tests is used to assess conditions such as asthma, chronic obstructive pulmonary disease (COPD), embolism (e.g., fatty or other embolism) during coronary arterial bypass surgery, and hypoxia. It is also used to assist in the diagnosis of respiratory failure, which is defined as a pO₂ less than 50 mm Hg and pCO₂ greater than 50 mm Hg. Blood gases can be valuable in the management of patients on ventilators or being weaned from ventilators. Blood gas values are used to determine acid-base status, the type of imbalance, and the degree of compensation as summarized in the following section. Restoration of pH to near-normal values is referred to as fully compensated balance. When pH values are moving in the same direction (i.e., increasing or decreasing) as the pCO₂ or HCO₃⁻, the imbalance is metabolic. When the pH values are moving in the opposite direction from the pCO₂ or HCO₃⁻, the imbalance is caused by respiratory disturbances. To remember this concept, the following mnemonic can be useful: MeTRO = Metabolic Together, Respiratory Opposite.

**RESULT:**

- Acid-base imbalance is determined by evaluating pH, pCO₂, and HCO₃⁻ values. pH less than 7.35 reflects an acidic state, whereas pH greater than 7.45 reflects alkalosis. pCO₂ and HCO₃⁻ determine whether the imbalance is respiratory or nonrespiratory (metabolic). Because a patient may have more than one imbalance and may also be in the process of compensating, the interpretation of blood gas values may not always seem straightforward.
Respiratory conditions that interfere with normal breathing will cause CO₂ to be retained in the blood. This results in an increase of circulating carbonic acid and a corresponding decrease in pH (respiratory acidosis). Acute respiratory acidosis can occur in acute pulmonary edema, severe respiratory infections, bronchial obstruction, pneumothorax, hemoptysis, open chest wounds, opiate poisoning, respiratory depressant drug therapy, and inhalation of air with a high CO₂ content. Chronic respiratory acidosis can be seen in patients with asthma, pulmonary fibrosis, emphysema, bronchiectasis, and respiratory depressant drug therapy. Alternately, respiratory conditions that increase the breathing rate will cause CO₂ to be removed from the alveoli more rapidly than it is being produced. This will result in an alkaline pH. Acute respiratory alkalosis may be seen in anxiety, hysteria, hyperventilation, and pulmonary embolus and with an increase in artificial ventilation. Chronic respiratory alkalosis may be seen in high fever, administration of drugs (e.g., salicylate and sulfonamide) that stimulate the respiratory system, hepatic coma, hypoxia of high altitude, and central nervous system (CNS) lesions or injury that result in stimulation of the respiratory center.

Metabolic (nonrespiratory) conditions that cause the excessive formation or decreased excretion of organic or inorganic acids result in metabolic acidosis. Some of these conditions include ingestion of salicylates, ethylene glycol, and methanol, as well as uncontrolled diabetes, starvation, shock, renal disease, and biliary or pancreatic fistula. Metabolic alkalosis results from conditions that increase pH, as can be seen in excessive intake of antacids to treat gastritis or peptic ulcer, excessive administration of HCO₃⁻, loss of stomach acid caused by protracted vomiting, cystic fibrosis, or potassium and chloride deficiencies.

**Respiratory Acidosis**
- Decreased pH
- Decreased O₂ saturation
- Increased pCO₂:
  - Acute intermittent porphyria
  - Anemia (severe)
  - Anorexia
  - Anoxia
  - Asthma
  - Atelectasis
  - Bronchitis
  - Bronchoconstriction
  - Carbon monoxide poisoning
  - Cardiac disorders
  - Congenital heart defects
  - Congestive heart failure
  - COPD
  - Cystic fibrosis
  - Depression of respiratory center
  - Drugs depressing the respiratory system
  - Electrolyte disturbances (severe)
  - Emphysema
  - Fever
  - Head injury
  - Hypercapnia
  - Hypothyroidism (severe)
  - Near drowning
  - Pleural effusion
  - Pneumonia
  - Pneumothorax
  - Poisoning
  - Poliomyelitis
  - Pulmonary edema
  - Pulmonary embolism
  - Pulmonary tuberculosis
  - Respiratory distress syndrome (adult and neonatal)
  - Respiratory failure
  - Sarcoidosis
Smoking
Tumor
• A decreased pO\textsubscript{2} that increases pCO\textsubscript{2}:
  Decreased alveolar gas exchange:
  cancer, compression or resection of lung, respiratory distress syndrome (newborns), sarcoidosis
Decreased ventilation or perfusion:
  asthma, bronchiectasis, bronchitis, cancer, croup, cystic fibrosis (mucoviscidosis), emphysema, granulomata, pneumonia, pulmonary infarction, shock
Hypoxemia: anesthesia, carbon monoxide exposure, cardiac disorders, high altitudes, near drowning, presence of abnormal hemoglobins
Hypoventilation: cerebrovascular incident, drugs depressing the respiratory system, head injury
Right-to-left shunt: congenital heart disease, intrapulmonary venoarterial shunting

**Compensation**
• Increased pO\textsubscript{2}:
  Hyperbaric oxygenation
  Hyperventilation
• Increased base excess:
  Increased HCO\textsubscript{3}\textsuperscript{-} to bring pH to (near) normal

**Respiratory Alkalosis**
• Increased pH
• Decreased pCO\textsubscript{2}:
  Anxiety
  CNS lesions or injuries that cause stimulation of the respiratory center
  Excessive artificial ventilation
  Fever
  Head injury
  Hyperthermia
  Hyperventilation
  Hysteria
  Salicylate intoxication

**Compensation**
• Decreased pO\textsubscript{2}:
  Rebreather mask
• Decreased base excess:
  Decreased HCO\textsubscript{3}\textsuperscript{-} to bring pH to (near) normal

**Metabolic Acidosis**
• Decreased pH
• Decreased HCO\textsubscript{3}\textsuperscript{-}
• Decreased base excess
• Decreased tCO\textsubscript{2}:
  Decreased excretion of H+: acquired (e.g., drugs, hypercalcemia), Addison’s disease, diabetic ketoacidosis, Fanconi’s syndrome, inherited (e.g., cystinosis, Wilson’s disease), renal failure, renal tubular acidosis
  Increased acid intake
  Increased formation of acids: diabetic ketoacidosis, high-fat/low-carbohydrate diets
  Increased loss of alkaline body fluids: diarrhea, excess potassium, fistula
  Renal disease

**Compensation**
• Decreased pCO\textsubscript{2}:
  Hyperventilation

**Metabolic Alkalosis**
• Increased pH
• Increased HCO\textsubscript{3}\textsuperscript{-}
• Increased base excess
• Increased tCO\textsubscript{2}:
  Alkali ingestion (excessive)
  Anoxia
  Gastric suctioning
  Hypochloremic states
  Hypokalemic states
  Potassium depletion: Cushing’s disease, diarrhea, diuresis, excessive vomiting, excessive ingestion of licorice, inadequate potassium intake, potassium-losing nephropathy, steroid administration
  Salicylate intoxication
  Shock
  Vomiting

**Compensation**
• Increased tCO\textsubscript{2}:
  Hypoventilation

**Critical Values:** Note and immediately report to the health care practitioner (HCP) any critically increased or decreased values and related symptoms.
### Arterial Blood Gas Parameter

<td>67 mm Hg</td>
</tr>
<tr>
<td>pO$_2$</td>
<td>45 mm Hg</td>
<td></td>
</tr>
</tbody>
</table>

### INTERFERING FACTORS:

- **Drugs that may cause an increase in HCO$_3^-$** include acetylsalicylic acid (initially), antacids, carbenicillin, carbenoxolone, ethacrynic acid, glycyrrhiza (licorice), laxatives, mafenide, and sodium bicarbonate.
- **Drugs that may cause a decrease in HCO$_3^-$** include acetazolamide, acetylsalicylic acid (long term or high doses), citrates, dimethadione, ether, ethylene glycol, fluorides, mercury compounds (laxatives), methylenedioxymphetamine, paraldehyde, and xylitol.
- **Drugs that may cause an increase in pCO$_2$** include acetylsalicylic acid, aldosterone bicarbonate, carbenicillin, carbenoxolone, corticosteroids, dexamethasone, ethacrynic acid, laxatives (chronic abuse), and x-ray contrast agents.
- **Drugs that may cause a decrease in pCO$_2$** include acetazolamide, acetylsalicylic acid, ethamivan, neuromuscular relaxants (secondary to postoperative hyperventilation), NSD 3004 (arterial long-acting carbonic anhydrase inhibitor), theophylline, tromethamine, and xylitol.
- **Drugs that may cause an increase in pO$_2$** include theophylline and urokinase.
- **Drugs that may cause a decrease in pO$_2$** include althesin, barbiturates, granulocyte-macrophage colony-stimulating factor, isoproterenol, and meperidine.

- Samples for blood gases are obtained by arterial puncture, which carries a risk of bleeding, especially in patients who have bleeding disorders or are taking medications for a bleeding disorder.
- Recent blood transfusion may produce misleading values.
- Specimens with extremely elevated white blood cell counts will undergo misleading decreases in pH resulting from cellular metabolism, if transport to the laboratory is delayed.
- Specimens collected soon after a change in inspired oxygen has occurred will not accurately reflect the patient's oxygenation status.
- Specimens collected within 20 to 30 min of respiratory passage suctioning or other respiratory therapy will not be accurate.
- Excessive differences in actual body temperature relative to normal body temperature will not be reflected in the results. Temperature affects the amount of gas in solution. Blood gas analyzers measure samples at 37°C (98.6°F); therefore, if the patient is hyperthermic or hypothermic, it is important to notify the laboratory of the patient's actual body temperature at the time the specimen was collected. Fever will increase actual pO$_2$ and pCO$_2$ values; therefore, the uncorrected values measured at 37°C will be falsely decreased. Hypothermia...
decreases actual $pO_2$ and $pCO_2$ values; therefore, the uncorrected values measured at 37°C will be falsely increased.

- A falsely increased $O_2$ saturation may occur because of elevated levels of carbon monoxide in the blood.
- $O_2$ saturation is a calculated parameter based on an assumption of 100% hemoglobin A. Values may be misleading when hemoglobin variants with different oxygen dissociation curves are present. Hemoglobin S will cause a shift to the right, indicating decreased oxygen binding. Fetal hemoglobin and methemoglobin will cause a shift to the left, indicating increased oxygen binding.
- Excessive amounts of heparin in the sample may falsely decrease pH, $pCO_2$, and $pO_2$.
- Citrates should never be used as an anticoagulant in evacuated collection tubes for venous blood gas determinations because citrates will cause a marked analytic decrease in pH.
- Air bubbles or blood clots in the specimen are cause for rejection. Air bubbles in the specimen can falsely elevate or decrease the results depending on the patient’s blood gas status. If an evacuated tube is used for venous blood gas specimen collection, the tube must be removed from the needle before the needle is withdrawn from the arm or else the sample will be contaminated with room air.
- Specimens should be placed in ice slurry immediately after collection because blood cells continue to carry out metabolic processes in the specimen after it has been removed from the patient. These natural life processes can affect pH, $pO_2$, $pCO_2$, and the other calculated values in a short period of time. The cold temperature provided by the ice slurry will slow down, but not completely stop, metabolic changes occurring in the sample over time. Iced specimens not analyzed within 60 min of collection should be rejected for analysis.

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess acid-base balance and oxygenation level of the blood.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex and anesthetics.
- Obtain a history of the patient’s respiratory system, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- Record the patient’s temperature.
- Indicate the type of oxygen, mode of oxygen delivery, and delivery rate as part of the test requisition process. Wait 30 min after a change in type or mode of oxygen delivery or rate for specimen collection.
Review the procedure with the patient and advise rest for 30 min before specimen collection. Explain to the patient that an arterial puncture may be painful. The site may be anesthetized with 1% to 2% lidocaine before puncture. Inform the patient that specimen collection and postprocedure care of the puncture site usually take 10 to 15 min. The person collecting the specimen should be notified beforehand if the patient is receiving anticoagulant therapy, or taking aspirin or other natural products that may prolong bleeding from the puncture site.

If the sample is to be collected by radial artery puncture, perform an Allen test before puncture to ensure that the patient has adequate collateral circulation to the hand if thrombosis of the radial artery occurs after arterial puncture. The modified Allen test is performed as follows: extend the patient’s wrist over a rolled towel. Ask the patient to make a fist with the hand extended over the towel. Use the second and third fingers to locate the pulses of the ulnar and radial arteries on the palmar surface of the wrist. (The thumb should not be used to locate these arteries because it has a pulse.) Compress both arteries and ask the patient to open and close the fist several times until the palm turns pale. Release pressure on the ulnar artery only. Color should return to the palm within 5 sec if the ulnar artery is functioning. This is a positive Allen test, and blood gases may be drawn from the radial artery site. The Allen test should then be performed on the opposite hand. The hand to which color is restored fastest has better circulation and should be selected for specimen collection.

*Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions unless by medical direction.

Prepare an ice slurry in a cup or plastic bag to have ready for immediate transport of the specimen to the laboratory.

**INTRATEST:**

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions and follow the general guidelines in Appendix A. Positively identify the patient and label the appropriate tubes with the corresponding patient demographics, date, and time of collection.

**Arterial:**

Perform an arterial puncture and collect the specimen in an air-free heparinized syringe. There is no demonstrable difference in results between samples collected in plastic syringes and samples collected in glass syringes. It is very important that no room air be introduced into the collection container because the gases in the room and in the sample will begin equilibrating immediately. The end of the syringe must be stoppered immediately after the needle is withdrawn and removed. Apply a pressure dressing over the puncture site. Samples should be mixed by gentle rolling of the syringe to ensure proper mixing of the heparin with the sample, which will prevent the formation of small clots leading to rejection of the sample. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag. Promptly transport the specimen to the laboratory for processing and analysis.

**Venous:**

Central venous blood is collected in a heparinized syringe.

Venous blood is collected percutaneously by venipuncture in a 5-mL
BLOOD GASES

green-top (heparin) tube (for adult patients) or a heparinized microtainer (for pediatric patients). The vacuum collection tube must be removed from the needle before the needle is removed from the patient’s arm. Apply a pressure dressing over the puncture site. Samples should be mixed by gentle rolling of the syringe to ensure proper mixing of the heparin with the sample, which will prevent the formation of small clots leading to rejection of the sample. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label can be protected from water in the ice slurry by first placing the specimen in a protective plastic bag. Promptly transport the specimen to the laboratory for processing and analysis.

Capillary:
Perform a capillary puncture and collect the specimen in two 250-microliter heparinized capillaries (scalp or heel for neonatal patients) or a heparinized microtainer (for pediatric patients). Observe standard precautions and follow the general guidelines in Appendix A. The capillary tubes should be filled as much as possible and capped on both ends. Some hospitals recommend that metal “fleas” be added to the capillary tube before the ends are capped. During transport, a magnet can be moved up and down the outside of the capillary tube to facilitate mixing and prevent the formation of clots, which would cause rejection of the sample. It is important to inform the laboratory or respiratory therapy staff of the number of fleas used so the fleas can be accounted for and removed before the sample is introduced into the blood gas analyzers. Fleas left in the sample may damage the blood gas equipment if allowed to enter the analyzer. Microtainer samples should be mixed by gentle rolling of the capillary tube to ensure proper mixing of the heparin with the sample, which will prevent the formation of small clots leading to rejection of the sample. Promptly transport the specimen to the laboratory for processing and analysis.

Cord Blood:
The sample may be collected directly from the cord, using a syringe. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label can be protected from water in the ice slurry by first placing the specimen in a protective plastic bag. Promptly transport the specimen to the laboratory for processing and analysis.

Scalp Sample:
Samples for scalp pH may be collected anaerobically before delivery in special scalp-sample collection capillaries and transported immediately to the laboratory for analysis. Some hospitals recommend that fleas be added to the scalp tube before the ends are capped. See preceding section on capillary collection for discussion of fleas.

POST-TEST:
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
Pressure should be applied to the puncture site for at least 5 min in the unanticoagulated patient and for at least 15 min in the case of a patient receiving anticoagulant therapy. Observe puncture site for bleeding or hematoma formation. Apply pressure bandage.
Observe the patient for signs or symptoms of respiratory acidosis, such as dyspnea, headache, tachycardia, pallor, diaphoresis, apprehension, drowsiness, coma, hypertension, or disorientation.
Teach the patient breathing exercises to assist with the appropriate exchange of oxygen and carbon dioxide.
Administer oxygen, if appropriate.
Teach the patient how to properly use the incentive spirometer device or mininebulizer, if ordered.

Observe the patient for signs or symptoms of respiratory alkalosis, such as tachypnea, restlessness, agitation, tetany, numbness, seizures, muscle cramps, dizziness, or tingling fingertips.

Instruct the patient to breathe deeply and slowly; performing this type of breathing exercise into a paper bag decreases hyperventilation and quickly helps the patient’s breathing return to normal.

Observe the patient for signs or symptoms of metabolic acidosis, such as rapid breathing, flushed skin, nausea, vomiting, dysrhythmias, coma, hypotension, hyperventilation, and restlessness.

Observe the patient for signs or symptoms of metabolic alkalosis, such as shallow breathing, weakness, dysrhythmias, tetany, hypokalemia, hyperactive reflexes, and excessive vomiting.

Nutritional considerations: Abnormal blood gas values may be associated with diseases of the respiratory system. Malnutrition is commonly seen in patients with severe respiratory disease for reasons including fatigue, lack of appetite, and gastrointestinal distress. Research has estimated that the daily caloric intake required for respiration of patients with COPD is 10 times higher than that of normal individuals. Inadequate nutrition can result in hypophosphatemia, especially in the respirator-dependent patient. During periods of starvation, phosphorus leaves the intracellular space and moves outside the tissue, resulting in dangerously decreased phosphorus levels.

Adequate intake of vitamins A and C is also important to prevent pulmonary infection and to decrease the extent of lung tissue damage. The importance of following the prescribed diet should be stressed to the patient and/or caregiver.

Water balance needs to be closely monitored in COPD patients. Fluid retention can lead to pulmonary edema.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include α₁-AT, anion gap, arterial/alveolar oxygen ratio, biopsy lung, bronchoscopy, carboxyhemoglobin, chest x-ray, chloride sweat, complete blood count hemoglobin, complete blood count WBC and diff, culture and smear for mycobacteria, culture bacterial sputum, culture viral, cytology sputum, electrolytes, Gram stain, IgE, lactic acid, lung perfusion scan, lung ventilation scan, osmolality, phosphorus, plethysmography, pleural fluid analysis, pulse oximetry, PFT, and TB skin tests.

Refer to the Cardiovascular, Genitourinary, and Respiratory System tables at the back of the book for related tests by body system.
Blood Groups and Antibodies

**SYNONYM/ACRONYM:** ABO group and Rh typing, blood group antibodies, type and screen, type and crossmatch.

**SPECIMEN:** Serum (2 mL) collected in a red-top tube or whole blood (2 mL) collected in a lavender-top (EDTA) tube.

**REFERENCE VALUE:** (Method: FDA-licensed reagents with glass slides, glass tubes, gel, or automated systems) Compatibility (no clumping or hemolysis).

**DESCRIPTION:** Blood typing is a series of tests that include the ABO and Rh blood-group system performed to detect surface antigens on red blood cells by an agglutination test and compatibility tests to determine antibodies against these antigens. The major antigens in the ABO system are A and B, although AB and O are also common phenotypes. The patient with A antigens has group A blood; the patient with B antigens has group B blood. The patient with both A and B antigens has group AB blood (universal recipient); the patient with neither A nor B antigens has group O blood (universal donor). Blood group and type is genetically determined. After 6 mo of age, individuals develop serum antibodies that react with A or B antigen absent from their own red blood cells. These are called *anti-A* and *anti-B* antibodies.

In ABO blood typing, the patient’s red blood cells mix with anti-A and anti-B sera, a process known as *forward grouping*. The process then reverses, and the patient’s serum mixes with type A and B cells in *reverse grouping*.

Generally, only blood with the same ABO group and Rh type as the recipient is transfused because the anti-A and anti-B antibodies are strong agglutinins that cause a rapid, complement-mediated destruction of incompatible cells. However, blood donations have decreased nationwide creating shortages in the available supply. Safe substitutions with blood of a different type are often needed.

</table>
group and/or Rh type may occur based on the inventory of available units. Many laboratories require consultation with the requesting health care provider (HCP) prior to issuing Rh-positive units to an Rh-negative individual.

ABO and Rh testing is also performed as a prenatal screen in pregnant women to identify the risk of hemolytic disease of the newborn. Although most of the anti-A and anti-B activity resides in the immunoglobulin M (IgM) class of immunoglobulins, some activity rests with immunoglobulin G (IgG). Anti-A and anti-B antibodies of the IgG class coat the red blood cells without immediately affecting their viability and can readily cross the placenta, resulting in hemolytic disease of the newborn. Individuals with type O blood frequently have more IgG anti-A and anti-B than other people; thus, ABO hemolytic disease of the newborn will affect infants of type O mothers almost exclusively (unless the newborn is also type O).

Major antigens of the Rh system are D (or Rh_0), C, E, c, and e. Individuals whose red blood cells possess D antigen are called Rh-positive; those who lack D antigen are called Rh-negative, no matter what other Rh antigens are present. Individuals who are Rh-negative produce anti-D antibodies when exposed to Rh-positive cells by either transfusions or pregnancy. These anti-D antibodies cross the placenta to the fetus and can cause hemolytic disease of the newborn or transfusion reactions if Rh-positive blood is administered.

INDICATIONS:
- Determine ABO and Rh compatibility of donor and recipient before transfusion (Type and Screen or Crossmatch).
- Determine anti-D antibody titer of Rh-negative mothers after sensitization by pregnancy with an Rh-positive fetus.
- Determine the need for a microdose of immunosuppressive therapy (e.g., with RhoGAM) during the first 12 wk of gestation or a standard dose after 12 weeks’ gestation for complications such as abortion, miscarriage, vaginal hemorrhage, ectopic pregnancy, or abdominal trauma.
- Determine Rh blood type and perform antibody screen of prenatal patients on initial visit to determine maternal Rh type and to indicate whether maternal red blood cells have been sensitized by any antibodies known to cause hemolytic disease of the newborn, especially anti-D antibody. Rh blood type, antibody screen, and antibody titration (if an antibody has been identified) will be rechecked at 28 weeks’ gestation and prior to injection of prophylactic standard dose of Rh(D) immune globulin Rhogam IM or Rhophylac IM or IV for Rh-negative mothers. These tests will also be repeated after delivery of an Rh-positive fetus to an Rh-negative mother and prior to injection of prophylactic standard dose of Rh(D) immune globulin (if maternal Rh-negative blood has not been previously sensitized with Rh-positive cells resulting in a positive anti-D antibody titer). A postpartum blood sample must be evaluated for fetal-maternal bleed on all Rh-negative mothers to determine the need for additional doses of Rh immune globulin. One
in 300 cases will demonstrate hemorrhage greater than 15 mL of blood and require additional Rh(D) immune globulin.

- Identify donor ABO and Rh blood type for stored blood.
- Identify maternal and infant ABO and Rh blood types to predict risk of hemolytic disease of the newborn.
- Identify the patient’s ABO and Rh blood type, especially before a procedure in which blood loss is a threat or blood replacement may be needed.

RESULT:

- ABO system: A, B, AB, or O specific to person
- Rh system: positive or negative specific to person
- Crossmatching: compatibility between donor and recipient
- Incompatibility indicated by clumping (agglutination) of red blood cells

*If blood units of exact match to the patient’s group and type are not available, a switch in ABO blood group is preferable to a change in Rh type. However, in extreme circumstances, Rh-positive blood can be issued to an Rh-negative recipient. It is very likely that the recipient will develop antibodies as the result of receiving Rh-positive red blood cells. Rh antibodies are highly immunogenic, and, once developed, the recipient can only receive Rh-negative blood for subsequent red blood cell transfusion.

CRITICAL VALUES:

Note and immediately report to the HCP any signs and symptoms associated with a blood transfusion reaction. Signs and symptoms of blood transfusion reaction range from mildly febrile to anaphylactic and may include chills, dyspnea, fever, headache, nausea, vomiting, palpitations and tachycardia, chest or back pain, apprehension, flushing, hives, angioedema, diarrhea, hypotension, oliguria, hemoglobinuria, renal failure, sepsis, shock, and jaundice. Complications from disseminated intravascular coagulation (DIC) may also occur.
Possible interventions in mildly febrile reactions would include slowing the rate of infusion, then verifying and comparing patient identification, transfusion requisition, and blood bag label. The patient should be monitored closely for further development of signs and symptoms. Administration of epinephrine may be ordered.

Possible interventions in a more severe transfusion reaction may include immediate cessation of infusion, notification of the HCP, keeping the IV line open with saline or lactated Ringer’s solution, collection of red- and lavender-top tubes for post-transfusion work-up, collection of urine, monitoring vital signs every 5 min, ordering additional testing if DIC is suspected, maintaining patent airway and blood pressure, and administering mannitol. See Appendix D for a more detailed description of transfusion reactions and potential nursing interventions.

INTERFERING FACTORS:
- Drugs including levodopa, methyldopa, methyldopate hydrochloride, and cephalaxin may cause a false positive result in Rh typing and in antibody screens.
- Recent administration of blood, blood products, dextran, or IV contrast medium causes cellular aggregation resembling agglutination in ABO typing.
- Contrast material such as iodine, barium, and gadolinium may interfere with testing.
- Abnormal proteins, cold agglutinins, and bacteremia may interfere with testing.
- Testing does not detect every antibody and may miss the presence of a weak antibody.
- History of bone marrow transplant, cancer, or leukemia may cause discrepancy in ABO typing.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to determine ABO blood group and Rh type.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune and hematopoietic systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent or past procedures, especially blood or blood product transfusion or bone marrow transplantation, that could complicate or interfere with test results.
- Obtain a list of the patient’s current medications including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.
- Make sure a written and informed consent has been signed prior to any transfusion of ABO- and Rh-compatible blood products.

INTRATEST:
- If the patient has a history of an allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate
tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Although correct patient identification is important for test specimens, it is crucial when blood is collected for type and crossmatch. Therefore, additional requirements are necessary, including the verification of two unique identifiers that could include any two unique patient demographics such as name, date of birth, social security number, hospital number, date, or blood bank number on requisition and specimen labels; completing and applying a wristband on the arm with the same information; and placing labels with the same information and blood bank number on blood sample tubes.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Inform patient of ABO blood and Rh type, and advise the patient to record the information on a card or other document normally carried.
- Inform women who are Rh-negative to inform the HCP of their Rh-negative status if they become pregnant or need a transfusion.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include Coomb’s antiglobulin, bilirubin, complete blood count, complete blood count hemoglobin, complete blood count platelet count, complete blood count RBC count, cold agglutinin, FDP, fecal analysis, GI blood loss scan, haptoglobin, Ig A, iron, Kleihauer-Betke, laproscopy abdominal, Meckel’s diverticulum scan, and UA.
- Refer to the Immune and Hematopoietic System tables at the back of the book for related tests by body system.

### Blood Pool Imaging

**SYNONYM/ACRONYM:** Cardiac blood pool scan, ejection fraction study, gated cardiac scan, radionuclide ventriculogram, wall motion study, MUGA.

**AREA OF APPLICATION:** Heart.

**CONTRAST:** Intravenous radioactive material.
DESCRIPTION: Multigated blood pool imaging (MUGA; also known as cardiac blood pool scan) is used to diagnose cardiac abnormalities involving the left ventricle and myocardial wall abnormalities by imaging the blood within the cardiac chamber rather than the myocardium. The ventricular blood pool can be imaged during the initial transit of a peripherally injected, intravenous bolus of radionuclide (first-pass technique) or when the radionuclide has reached equilibrium concentration. The patient’s electrocardiogram (ECG) is synchronized to the gamma camera imager and computer and thereby termed “gated.” For multigated studies, technetium-99m (Tc-99m) pertechnetate is injected after an injection of pyrophosphate, allowing the labeling of circulating red blood cells; Tc-99m sulfur colloid is used for first-pass studies. Studies detect abnormalities in heart wall motion at rest or with exercise, ejection fraction, ventricular dilation, stroke volume, and cardiac output. The MUGA procedure, performed with the heart in motion, is used to obtain multiple images of the heart in contraction and relaxation during an R-to-R cardiac cycle. The resulting images can be displayed in a cinematic mode to visualize cardiac function. Repetitive data acquisitions are possible during graded levels of exercise, usually a bicycle ergometer or handgrip, to assess ventricular functional response to exercise.

After the administration of sublingual nitroglycerin, the MUGA scan can evaluate the effectiveness of the drug on ventricular function.

INDICATIONS:
• Aid in the diagnosis of myocardial infarction
• Aid in the diagnosis of true or false ventricular aneurysms
• Aid in the diagnosis of valvular heart disease and determining the optimal time for valve replacement surgery
• Detect left-to-right shunts and determine pulmonary-to-systemic blood flow ratios, especially in children
• Determine cardiomyopathy
• Determine drug cardiotoxicity to stop therapy before development of congestive heart failure
• Determine ischemic coronary artery disease
• Differentiate between chronic obstructive pulmonary disease and left ventricular failure
• Evaluate ventricular size, function, and wall motion after an acute episode or in chronic heart disease
• Quantitate cardiac output by calculating global or regional ejection fraction

RESULT:
Normal findings in:
• Normal wall motion, ejection fraction (55% to 65%), coronary blood flow, ventricular size and function, and symmetry in contractions of the left ventricle
Abnormal findings in:
• Abnormal wall motion (akinesia or dyskinesia)
• Cardiac hypertrophy
• Cardiac ischemia
• Enlarged left ventricle
• Infarcted areas are akinetic
• Ischemic areas are hypokinetic
• Myocardial infarction

Critical values:
• Myocardial infarction

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

Interfering factors:
This procedure is contraindicated for:
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
• Dipyridamole testing is not performed in patients with anginal pain at rest or in patients with severe atherosclerotic coronary vessels.
• Chemical stress with vasodilators should not be done to patients having asthma; bronchospasm can occur.

Factors that may impair clear imaging:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images

Other considerations:
• Conditions such as chest wall trauma, cardiac trauma, angina that is difficult to control, significant cardiac arrhythmias, or a recent cardioversion procedure may affect test results.

Atrial fibrillation and extrasystoles invalidate the procedure.
• Suboptimal cardiac stress or patient exhaustion, preventing maximum heart rate testing, will affect results when the procedure is done in conjunction with exercise testing.
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation.

Nursing implications and procedure

Pretest:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the pumping action of the heart.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- Obtain a history of the patient’s cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Access additional resources at davisplus.fadavis.com
Obtain a list of the patient’s current medications including herbs, nutritional supplements, and nutraceuticals (see Appendix F).

Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department, by a HCP specializing in this procedure and takes approximately 60 min.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient to wear walking shoes for the treadmill or bicycle exercise. Emphasize to the patient the importance of reporting fatigue, pain, or shortness of breathe.

Instruct the patient to remove external metallic objects from the area to be examined prior to the procedure.

The patient should fast and restrict fluids for 4 hr prior to the procedure. Instruct the patient to withhold medications for 24 hr before the test as ordered by the HCP. Protocols may vary from facility to facility.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

Ensure that the patient has complied with dietary and medication restrictions.

Ensure that the patient has removed external metallic objects from the area to be examined prior to the procedure.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.

Have emergency equipment readily available.

**POST-TEST:**

Record baseline vital signs and assess neurological status. Protocols may vary from facility to facility.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

The patient is placed at rest in the supine position on the scanning table.

Expose the chest and attach the ECG leads. Record baseline readings.

IV radionuclide is administered and the heart is scanned with images taken in various positions over the entire cardiac cycle.

When the scan is to be done under exercise conditions, the patient is assisted onto the treadmill or bicycle ergometer and is exercised to a calculated 80% to 85% of the maximum heart rate as determined by the protocol selected. Images are done at each exercise level and begun immediately after injection of the radionuclide.

If nitroglycerin is given, a HCP assessing the baseline MUGA scan injects the medication. Additional scans are repeated until blood pressure reaches the desired level.

Patients who cannot exercise are given dipyridamole before the radionuclide is injected.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

Remove the needle or catheter and apply a pressure dressing over the puncture site.

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the
radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.

➧ No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.

➧ Evaluate the patient’s vital signs. Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by HCP. Compare with baseline values. Protocols may vary from facility to facility.

➧ Instruct the patient to resume usual dietary, medication, and activity, as directed by the HCP.

➧ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

➧ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

➧ Monitor ECG tracings and compare with baseline readings until stable.

➧ Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

➧ Instruct the patient in the care and assessment of the injection site. Observe for bleeding, hematoma formation, and inflammation.

➧ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.

➧ Instruct the patient to immediately flush the toilet, and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.

➧ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.

Nutritional considerations: A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.

➧ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

➧ Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

➧ Depending on the results of this procedure, additional testing may be needed to evaluate and determine the need for a change in therapy or progression of the disease process. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

➧ Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, ANP, blood gases, BNP, calcium, ionized calcium, cholesterol (total, HDL, and LDL), CRP, CT cardiac scoring, CK and isoenzymes, culture viral, echocardiography, echocardiography transesophageal, ECG, exercise stress test, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI chest, MI infarct scan, myocardial perfusion heart scan, myoglobin, pericardial fluid analysis, PET heart scan, potassium, triglycerides, and troponin.

➧ Refer to the Cardiovascular System table at the back of the book for related tests by body system.
**Bone Mineral Densitometry**

**SYNONYM/ACRONYM:** Ultrasound densitometry, DEXA, DXA, SXA, QCT, RA.

**Dual-energy x-ray absorptiometry (DEXA, DXA):** Two x-rays of different energy levels measure bone mineral density and predict risk of fracture.

**Single-energy x-ray absorptiometry (SXA):** A single-energy x-ray measures bone density at peripheral sites.

**Quantitative computed tomography (QCT):** QCT is used to examine the lumbar vertebrae. It measures trabecular and cortical bone density. Results are compared to a known standard. This test is the most expensive and involves the highest radiation dose of all techniques.

**Radiographic absorptiometry (RA):** A standard x-ray of the hand. Results are compared to a known standard.

**Ultrasound densitometry:** Studies bone mineral content in peripheral densitometry sites such as the heel or wrist. It is not as precise as x-ray techniques, but less expensive than other techniques.

**AREA OF APPLICATION:** Lumbar spine, heel, hip, wrist, whole body.

**CONTRAST:** None.

**DESCRIPTION:** Bone mineral density (BMD) can be measured at any of several body sites, including the spine, hip, wrist, and heel. Machines to measure BMD include computed tomography (CT), radiographic absorptiometry, ultrasound, single-energy x-ray absorptiometry (SXA), and most commonly, dual-energy x-ray absorptiometry (DEXA). The radiation exposure from SXA and DEXA machines is approximately one-tenth that of a standard chest x-ray.

The BMD values measured by the various techniques cannot be directly compared. Therefore, they are stated in terms of standard deviation (SD) units. The patient’s T-score is the number of SD units above or below the average BMD in young adults. A Z-score is the number of SD units above or below the average value for a person of the same age as the measured patient. For most BMD readings, 1 SD is equivalent to 10% to 12% of the average young-normal BMD value. A T-score of –2.5 is therefore equivalent to a bone mineral loss of 30% when compared to a young adult.

**INDICATIONS:**

Osteoporosis is a condition characterized by low BMD, which results in increased risk of fracture. The National Osteoporosis Foundation estimates that 4 to 6 million post-menopausal women in the United States have osteoporosis, and an additional 13 to 17 million (30% to 50%) have low bone density at the hip. It is estimated that one of every two women will experience a
fracture as a result of low bone mineral content in her lifetime. The measurement of BMD gives the best indication of risk for a fracture. The lower the BMD, the greater the risk of fracture. The most common fractures are those of the hip, vertebrae, and distal forearm. Bone mineral loss is a disease of the entire skeleton and not restricted to the areas listed. The effect of the fractures has a wide range, from complete recovery to chronic pain, disability, and possible death.

- Determine the mineral content of bone
- Determine a possible cause of amenorrhea
- Establish a diagnosis of osteoporosis
- Evaluate bone demineralization associated with chronic renal failure
- Evaluate bone demineralization associated with immobilization
- Monitor changes in BMD due to medical problems or therapeutic intervention
- Predict future fracture risk

RESULT:
- T-score estimates the actual fracture risk compared to young adults.
- Normal bone mass is designated as a T-score value not less than –1.
- Osteoporosis is defined as a BMD T-score value less than –2.5.
- Low bone mass or osteopenia has T-scores from –1 to –2.5.
- Fracture risk increases as BMD declines from young-normal levels (low T-scores).
- Low Z-scores in older adults can be misleading because low BMD is very common.
- Z-scores estimate fracture risk compared to others of the same age (versus young-normal adults).

CRITICAL VALUES: N/A

INTERFERING FACTORS OR FACTORS ASSOCIATED WITH INCREASED RISK OF OSTEOPOROSIS:
This procedure is contraindicated for:
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.

Factors that may impair clear imaging:
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Metallic objects within the examination field (e.g., jewelry, earrings, and/or dental amalgams), which may inhibit organ visualization and can produce unclear images

Other considerations:
- The use of anticonvulsant drugs, cytotoxic drugs, tamoxifen, glucocorticoid, lithium, or heparin, as well as increased alcohol intake, increased aluminum levels, excessive thyroxin, renal dialysis, or smoking, may affect the test results by either increasing or decreasing the bone mineral content.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of exposure to radiation.
Other considerations as a result of altered BMD, not the BMD testing process:

- Vertebral fractures may cause complications including back pain, height loss, and kyphosis.
- Limited activity may result, including difficulty bending and reaching.
- Patient may have poor self-esteem resulting from the cosmetic effects of kyphosis.
- Potential restricted lung function may result from fractures.
- Fractures may alter abdominal anatomy, resulting in constipation, pain, distention, and diminished appetite.
- Potential for a restricted lifestyle may result in depression and other psychological symptoms.
- Possible increased dependency on family for basic care may occur.

INTRATEST:

- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided. Patient’s clothing may not need to be removed unless it contains metal that would interfere with the test.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in a supine position on a flat table with foam wedges, which help maintain position and immobilization.

POST-TEST:

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of perceived
loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms, previous BMD values, and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ALP, antibodies anticyclic citrullinated peptide, ANA, arthrogram, arthroscopy, biopsy bone, bone scan, calcium, CRP, collagen cross-linked telopeptides, CT pelvis, CT spine, ESR, MRI musculoskeletal, MRI pelvis, osteocalcin, PTH, phosphorus, radiography bone, RF, synovial fluid analysis, and vitamin D.
- Refer to the Musculoskeletal System table in the back of the book for related tests by body system.

**SYNONYM/ACRONYM:** Bone imaging, radionuclide bone scan, bone scintigraphy, whole-body bone scan.

**AREA OF APPLICATION:** Bone/skeleton.

**CONTRAST:** Intravenous radioactive material (diphosphonate compounds), usually combined with technetium-99m.

**DESCRIPTION:** This nuclear medicine scan assists in diagnosing and determining the extent of primary and metastatic bone disease and bone trauma, and monitors the progression of degenerative disorders. Abnormalities are identified by scanning 1 to 3 hr after the intravenous injection of a radionuclide such as technetium-99m methylene diphosphonate. Areas of increased uptake and activity on the bone scan represent abnormalities unless they occur in normal areas of increased activity, such as the sternum, sacroiliac, clavicle, and scapular joints in adults, and growth centers and cranial sutures in children. The radionuclide mimics calcium physiologically and therefore localizes in bone with an intensity proportional to the degree of metabolic activity. Gallium, magnetic resonance imaging (MRI), or white blood cell scanning can follow a bone scan to obtain a more sensitive study if acute inflammatory
conditions such as osteomyelitis or septic arthritis are suspected. In addition, bone scan can detect fractures in patients who continue to have pain, even though x-rays have proved negative. A gamma camera detects the radiation emitted from the injected radioactive material. Whole-body or representative images of the skeletal system can be obtained.

**INDICATIONS:**
- Aid in the diagnosis of benign tumors or cysts
- Aid in the diagnosis of metabolic bone diseases
- Aid in the diagnosis of osteomyelitis
- Aid in the diagnosis of primary malignant bone tumors (e.g., osteogenic sarcoma, chondrosarcoma, Ewing’s sarcoma, metastatic malignant tumors)
- Aid in the detection of traumatic or stress fractures
- Assess degenerative joint changes or acute septic arthritis
- Assess suspected child abuse
- Confirm temporomandibular joint derangement
- Detect Legg-Calvé-Perthes disease
- Determine the cause of unexplained bone or joint pain
- Evaluate the healing process following fracture, especially if an underlying bone disease is present
- Evaluate prosthetic joints for infection, loosening, dislocation, or breakage
- Evaluate tumor response to radiation or chemotherapy
- Identify appropriate site for bone biopsy, lesion excision, or debridement

**RESULT:**

**Normal findings in:**
- No abnormalities, as indicated by homogeneous and symmetric distribution of the radionuclide throughout all skeletal structures

**Abnormal findings in:**
- Bone necrosis
- Degenerative arthritis
- Fracture
- Legg-Calvé-Perthes disease
- Metastatic bone neoplasm
- Osteomyelitis
- Paget’s disease
- Primary metastatic bone tumors
- Renal osteodystrophy
- Rheumatoid arthritis

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

*This procedure is contraindicated for:*
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

*Factors that may impair clear imaging:*
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects within the examination field (e.g., jewelry, earrings, and/or dental amalgams), which may inhibit organ visualization and can produce unclear images.
- Retained barium from a previous radiological procedure may affect the image.
- A distended bladder may obscure pelvic detail.
- Other nuclear scans done within the previous 24 to 48 hr may alter image.

*Other considerations:*
- The existence of multiple myeloma or thyroid cancer can result in a false-negative scan for bone abnormalities.
- Improper injection of the radionuclide may allow the tracer to
seep deep into the muscle tissue, producing erroneous hot spots.

- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

### Nursing Implications and Procedure

#### PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses bone disease before it can be detected with plain x-ray images.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- Obtain a history of results of the patient’s musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in a nuclear medicine department by a HCP specializing in this procedure, and takes approximately 30 to 60 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.
- Instruct the patient to remove jewelry and other metallic objects in the area to be examined.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

#### INTRATEST:
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
Administer sedative to a child or to an uncooperative adult, as ordered.

Place the patient in a supine position on a flat table with foam wedges to help maintain position and immobilization.

IV radionuclide is administered and images are taken immediately to assess blood flow to the bones.

After a delay of 2 to 3 hr to allow the radionuclide to be taken up by the bones, multiple images are obtained over the complete skeleton. Delayed views may be taken up to 24 hr after the injection.

Remove the needle or catheter and apply a pressure dressing over the puncture site.

The patient may be imaged by single-photon emission computed tomography (SPECT) techniques to further clarify areas of suspicious radionuclide localization.

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.

No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.

Instruct the patient to resume medication and activity as directed by the HCP.

Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

Instruct the patient in the care and assessment of the injection site and to observe for bleeding, hematoma formation, and inflammation.

If a woman who is breastfeeding must have a nuclear scan; she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.

Instruct the patient to immediately flush the toilet, and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.

Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash ungloved hands after the gloves are removed.

Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include antibodies, anticyclic citrullinated peptide, ANA, arthroscopy, BMD, calcium, CRP, collagen cross-linked telopeptide, CT pelvis, CT spine, culture blood, ESR, MRI musculoskeletal, MRI pelvis, osteocalcin, radiography bone, synovial fluid analysis, RF, and white blood cell scan.

Refer to the Musculoskeletal System table at the back of the book for related tests by body system.
**Bronchoscopy**

**SYNONYM/ACRONYM:** Flexible bronchoscopy.

**AREA OF APPLICATION:** Bronchial tree, larynx, trachea.

**CONTRAST:** None.

**DESCRIPTION:** This procedure provides direct visualization of the larynx, trachea, and bronchial tree by means of either a rigid or a flexible bronchoscope. A fiberoptic bronchoscope with a light incorporated is guided into the tracheobronchial tree. A local anesthetic may be used to allow the scope to be inserted through the mouth or nose into the trachea and into the bronchi. The patient must breathe during insertion and with the scope in place. The purpose of the procedure is both diagnostic and therapeutic.

The rigid bronchoscope allows visualization of the larger airways, including the lobar, segmental, and subsegmental bronchi, while maintaining effective gas exchange. Rigid bronchoscopy is preferred when large volumes of blood or secretions need to be aspirated, foreign bodies are to be removed, large-sized biopsy specimens are to be obtained, and for most bronchoscopies in children.

The flexible fiberoptic bronchoscope has a smaller lumen that is designed to allow for visualization of all segments of the bronchial tree. The accessory lumen of the bronchoscope is used for tissue biopsy, bronchial washings, instillation of anesthetic agents and medications, and to obtain specimens with brushes for cytologic examination. In general, fiberoptic bronchoscopy is less traumatic to the surrounding tissues than the larger rigid bronchoscopes. Fiberoptic bronchoscopy is performed under local anesthesia; patient tolerance is better for fiberoptic bronchoscopy than for rigid bronchoscopy.

**INDICATIONS:**

- Detect end-stage bronchogenic cancer
- Detect lung infections and inflammation
- Determine etiology of persistent cough, hemoptysis, hoarseness, unexplained chest x-ray abnormalities, and/or abnormal cytologic findings in sputum
- Determine extent of smoke-inhalation or other traumatic injury
- Evaluate airway patency; aspirate deep or retained secretions
- Evaluate endotracheal tube placement or possible adverse sequelae to tube placement
- Evaluate possible airway obstruction in patients with known or suspected sleep apnea
- Evaluate respiratory distress and tachypnea in an infant to rule out tracheoesophageal fistula or other congenital anomaly
• Identify bleeding sites and remove clots within the tracheobronchial tree
• Identify hemorrhagic and inflammatory changes in Kaposi’s sarcoma
• Intubate patients with cervical spine injuries or massive upper airway edema
• Remove foreign body
• Treat lung cancer through instillation of chemotherapeutic agents, implantation of radioisotopes, or laser palliative therapy

RESULT:

Normal findings in:
• Normal larynx, trachea, bronchi, bronchioles, and alveoli

Abnormal findings in:
• Abscess
• Bronchial diverticulum
• Bronchogenic cancer
• Coccidioidomycosis, histoplasmosis, blastomycosis, phycomycosis
• Foreign bodies
• Inflammation
• Interstitial pulmonary disease
• Opportunistic lung infections (e.g., pneumocystis, nocardia, cytomegalovirus)
• Strictures
• Tuberculosis
• Tumors

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with disorders that limit extension of the neck
• Patients with severe obstructive tracheal conditions
• Patients with or having the potential for respiratory failure; introduction of the bronchoscope alone may cause a 10 to 20 mm Hg drop in PaO₂

Factors that may impair the results of the examination:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Metallic objects within the examination field (e.g., jewelry, earrings, and/or dental amalgams), which may inhibit organ visualization and can produce unclear images

Other considerations:
• Hypoxemic or hypercapnic states require continuous oxygen administration.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient the procedure assesses the lungs and respiratory system.
• Obtain a history of the patient’s complaints or symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, and anesthetics.
• Obtain a history of the patient’s immune and respiratory systems,
symptoms and results of previously performed laboratory tests, and diagnostic and surgical procedures.

Note any recent procedures that can interfere with test results. Ensure that this procedure is performed before an upper gastrointestinal study or barium swallow.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.

Review the procedure with the patient. Instruct that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Explain that a sedative and/or analgesia may be administered to promote relaxation and reduce discomfort prior to the bronchoscopy. Atropine is usually given before bronchoscopy examinations to reduce bronchial secretions and prevent vagally induced bradycardia. Meperidine (Demerol) or morphine may be given as a sedative. Lidocaine is sprayed in the patient’s throat to reduce discomfort caused by the presence of the tube. Inform the patient that the procedure is performed in a GI lab or radiology department, under sterile conditions, by a health care provider (HCP) specializing in this procedure. The procedure usually takes about 30 to 60 min to complete.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics. The patient should fast and restrict fluids for 8 hr prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Protocols may vary from facility to facility.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

Ensure that the patient has complied with food, fluid, and medication restrictions for 8 hr prior to the procedure.

Ensure that the patient has removed dentures, jewelry, and external metallic objects in the area to be examined prior to the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and change into the gown, robe, and foot coverings provided.

Avoid using morphine sulfate in those with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location, especially left or right lung.

Assist the patient to a comfortable position, and direct the patient to breathe normally during the beginning of the general anesthesia. Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
Record baseline vital signs and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

**Rigid Bronchoscopy:**
The patient is placed in the supine position and a general anesthetic is administered. The patient’s neck is hyperextended, and the lightly lubricated bronchoscope is inserted orally and passed through the glottis. The patient’s head is turned or repositioned to aid visualization of various segments.

After inspection, the bronchial brush, suction catheter, biopsy forceps, laser, and electrocautery devices are introduced to obtain specimens for cytologic or microbiologic study or for therapeutic procedures.

If a bronchial washing is performed, small amounts of solution are instilled into the airways and removed.

After the procedure, the bronchoscope is removed and the patient is placed in a side-lying position with the head slightly elevated to promote recovery.

**Fiberoptic Bronchoscopy:**
Provide mouth care to reduce oral bacterial flora.

The patient is placed in a sitting position while the tongue and oropharynx are sprayed or swabbed with local anesthetic. Provide an emesis basin for the increased saliva and encourage the patient to spit out the saliva because the gag reflex may be impaired. When loss of sensation is adequate, the patient is placed in a supine or side-lying position. The fiberoptic scope can be introduced through the nose, the mouth, an endotracheal tube, a tracheostomy tube, or a rigid bronchoscope. Most common insertion is through the nose. Patients with copious secretions or massive hemoptysis, or in whom airway complications are more likely, may be intubated before the bronchoscopy.

Additional local anesthetic is applied through the scope as it approaches the vocal cords and the carina, eliminating reflexes in these sensitive areas. The fiberoptic approach allows visualization of airway segments without having to move the patient’s head through various positions.

After visual inspection of the lungs, tissue samples are collected from suspicious sites by bronchial brush or biopsy forceps to be used for cytologic and microbiologic studies.

After the procedure, the bronchoscope is removed. Patients who had local anesthesia are placed in a semi-Fowler’s position to recover.

**General:**
Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).

Place tissue samples in properly labeled specimen containers containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods.

Inform the patient that he or she may experience some throat soreness and hoarseness. Instruct patient to treat throat discomfort with lozenges and warm gargles when the gag reflex returns.

Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature changes. Protocols may vary from facility to facility.

Emergency resuscitation equipment should be readily available if the vocal cords become spastic after intubation.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia,
hyperpnea, hypertension, palpitations, nausea, or vomiting.

Observe the patient for hemoptysis, difficulty breathing, cough, air hunger, excessive coughing, pain, or absent breathing sounds over the affected area. Report to HCP.

Evaluate the patient for symptoms indicating the development of pneumothorax, such as dyspnea, tachypnea, anxiety, decreased breathing sounds, or restlessness. A chest x-ray may be ordered to check for the presence of this complication.

Evaluate the patient for symptoms of empyema, such as fever, tachycardia, malaise, or elevated white blood cell count.

Observe the patient’s sputum for blood if a biopsy was taken, because large amounts of blood may indicate the development of a problem; a small amount of streaking is expected. Evaluate the patient for signs of bleeding such as tachycardia, hypotension, or restlessness.

Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.

Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Instruct the patient to use lozenges or gargle for throat discomfort. Inform the patient of smoking cessation programs as appropriate. Malnutrition is commonly seen in patients with severe respiratory disease for numerous reasons, including fatigue, lack of appetite, and gastrointestinal distress. Adequate intake of vitamins A and C is also important to prevent pulmonary infection and to decrease the extent of lung tissue damage. The importance of following the prescribed diet should be stressed to the patient/caregiver. Educate the patient regarding access to counseling services, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include arterial/alveolar oxygen ratio, antibodies, anti-glomerular basement membrane, biopsy lung, blood gases, chest x-ray, complete blood count, CT thorax, culture and smear mycobacteria, culture sputum, culture viral, cytology sputum, gram stain, lung perfusion scan, lung ventilation scan, MRI chest, mediastinoscopy, and pulse oximetry.

  - Refer to the Immune and Respiratory System tables at the back of the book for related tests by body system.
B-Type Natriuretic Peptide and Pro-B-Type Natriuretic Peptide

SYNONYM/ACRONYM: BNP and Pro-BNP.

SPECIMEN: Plasma (1 mL) collected in a plastic, lavender-top (EDTA) tube.

REFERENCE VALUE: (Method: Immunochemiluminometric for BNP; immuno(electro)chemiluminescence for Pro-BNP).

DESCRIPTION: The peptides B-type natriuretic peptide (BNP) and atrial natriuretic peptide (ANP) assist in the regulation of fluid balance and blood pressure. BNP, Pro-BNP, and ANP are useful markers in the diagnosis of congestive heart failure. BNP or brain natriuretic peptide, first isolated in the brain of pigs, is a neurohormone synthesized primarily in the ventricles of the human heart in response to increases in ventricular pressure and volume. Circulating levels of BNP and Pro-BNP increase in proportion to the severity of heart failure. A Rapid BNP point-of-care immunoassay may be performed, in which a venous blood sample is collected, placed on a strip, and inserted into a device that measures BNP. Results are completed in 10 to 15 min.

- Assist in the diagnosis of heart failure
- Assist in differentiating heart failure from pulmonary disease
- Screen for left ventricular dysfunction and therefore need for echocardiography for further assessment

RESULT:

**Increased in:**

*BNP is secreted in response to increased hemodynamic load caused by physiological stimuli as with ventricular stretch or endocrine stimuli from the aldosterone/renin system*

- Cardiac inflammation (myocarditis, cardiac allograft rejection)
- Cirrhosis
- Cushing’s syndrome
- Heart failure
- Kawasaki disease
- Left ventricular hypertrophy
- Myocardial infarction
- Primary hyperaldosteronism
- Primary pulmonary hypertension
- Renal failure
- Ventricular dysfunction

**Decreased in:** N/A

CRITICAL VALUES: N/A
B-TYPE NATRIURETIC PEPTIDE AND PRO-B-TYPE NATRIURETIC PEPTIDE

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is primarily used to identify congestive heart failure.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain to the patient that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A written report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Treatment considerations for CHF: Ensure that the patient (if not currently taking) is placed on an angiotensin-converting enzyme inhibitor, β-blocker, and diuretic; and monitored with daily weights.
- Nutritional considerations: Instruct patients to consume a variety of foods within the basic food groups, eat foods high in potassium when taking diuretics, eat a diet high in fiber (25 to 35 g/d), maintain a healthy weight, be physically active, limit salt intake to 2000 mg/d, limit alcohol intake, and be a nonsmoker.
- Nutritional considerations: Foods high in potassium include citrus fruits such as bananas, strawberries, oranges; cantaloupes; green leafy vegetables such as spinach and broccoli; dried fruits such as dates, prunes, and raisins; legumes such as peas and pinto beans; nuts and whole grains.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include AST, ANF, calcium and ionized calcium, CRP, CK and isoenzymes, CT scoring, echocardiography, glucose, homocysteine, Holter monitor, LDH and isoenzymes, magnesium, MRI chest, MI scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, and troponin.
- Refer to the Cardiovascular System table in the back of the book for related tests by body system.

DESCRIPTION: Calcitonin, also called thyrocalcitonin, is secreted by the parafollicular or C cells of the thyroid gland in response to elevated serum calcium levels. Calcitonin antagonizes the effects of parathyroid hormone and vitamin D so that calcium continues to be laid down in bone rather than reabsorbed into the blood.

Calcitonin also increases renal clearance of magnesium and inhibits tubular reabsorption of phosphates. The net result is that calcitonin decreases the serum calcium level. The pentagastrin (Peptavlon) provocation test and the calcium pentagastrin provocation test are useful for diagnosing medullary thyroid cancer.
INDICATIONS:
• Assist in the diagnosis of hyperparathyroidism
• Assist in the diagnosis of medullary thyroid cancer
• Evaluate altered serum calcium levels
• Monitor response to therapy for medullary thyroid carcinoma
• Predict recurrence of medullary thyroid carcinoma
• Screen family members of patients with medullary thyroid carcinoma (20% have a familial pattern)

RESULT:
Increased in:
• Alcoholic cirrhosis (Release of calcium from body stores related to acute instances of malnutrition)
• Cancer of the breast, lung, and pancreas (Metastasis of calcitonin-producing cells to other organs)
• Carcinoid syndrome (Calcitonin-producing tumor cells)
• C-cell hyperplasia (Increased production due to hyperplasia)
• Chronic renal failure (Increased excretion of calcium and retention of phosphorus results in release of calcium from body stores; C cells respond to an increase in serum calcium levels)
• Ectopic secretion (Especially neuroendocrine origins)
• Hypercalcemia (any cause) (Increased production by C cells in response to increased calcium levels)
• Medullary thyroid cancer (Overproduction by cancerous cells)
• MEN Type II (Calcitonin-producing tumor cells)
• Pancreatitis (Related to alcoholism or hypercalcemia)
• Pernicious anemia (Related to hypergastrinemia)
• Pheochromocytoma (Calcitonin-producing tumor cells)
• Pregnancy (late) (Related to increased maternal loss of circulating calcium to developing fetus; release of calcium from maternal stores stimulates increased release of calcitonin)
• Pseudohypoparathyroidism (Release of calcium from body stores initiates feedback response from C cells)
• Thyroiditis (Calcitonin-producing tumor cells)
• Zollinger-Ellison syndrome (related to hypergastrinemia)

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may increase calcitonin levels include calcium, epinephrine, estrogens, glucagon, oral contraceptives, pentagastrin, and sinalide.
• Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when radioimmunoassay is the test method.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to detect C-cell hyperplasia
Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient’s endocrine, genitourinary, and musculoskeletal systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.

Note any recent procedures that can interfere with test results.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min; a few extra minutes are required to administer the stimulation tests. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

The patient should fast for 10 to 12 hr before specimen collection. Protocols may vary from facility to facility.

There are no fluid or medication restrictions unless by medical direction.

Prepare an ice slurry in a cup or plastic bag to have ready for immediate transport of the specimen to the laboratory. Prechill the collection tube in the ice slurry.

**INTRATEST:**

Ensure that the patient has complied with dietary restrictions and pretesting preparations; assure that food has been restricted for at least 10 to 12 hr prior to the procedure.

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions.

Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a prechilled tube.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

The sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag. Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Instruct the patient to resume usual diet as directed by the HCP.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include ACTH, biopsy thyroid, calcium, cancer antigens, catecholamines, complete blood count, gastrin stimulation test,
CALCIUM, BLOOD

SYNONYM/ACRONYM: Total calcium, Ca.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

DESCRIPTION: Calcium, the most abundant cation in the body, participates in almost all of the vital processes. Calcium concentration is largely regulated by the parathyroid glands and by the action of vitamin D. Of the body’s calcium reserves, 98% to 99% is stored in the teeth and skeleton. Calcium values are higher in children because of growth and active bone formation. About 45% of the total amount of blood calcium circulates as free ions that participate in coagulation, neuromuscular conduction, intracellular regulation, glandular secretion, and control of skeletal and cardiac muscle contractility. The remaining calcium is bound to circulating proteins (40% bound mostly to albumin) and anions (15% bound to anions such as bicarbonate, citrate, phosphate, and lactate) and plays no physiological role. Calcium values can be adjusted up or down by 0.8 mg/dL for every 1 g/dL that albumin is greater than or less than 4 g/dL.

Refer to the Endocrine, Genitourinary, and Musculoskeletal System tables at the back of the book for related tests by body system.
Calcium and phosphorus levels are inversely proportional.

Fluid and electrolyte imbalances are often seen in patients with serious illness or injury; in these clinical situations, the normal homeostatic balance of the body is altered. During surgery or in the case of a critical illness, bicarbonate, phosphate, and lactate concentrations can change dramatically. Therapeutic treatments may also cause or contribute to electrolyte imbalance. This is why total calcium values can sometimes be misleading. Abnormal calcium levels are used to indicate general malfunctions in various body systems. Ionized calcium is used in more specific conditions (see monograph titled “Calcium, Ionized”).

Calcium values should be interpreted in conjunction with results of other tests. Normal calcium with an abnormal phosphorus value indicates impaired calcium absorption (possibly because of altered parathyroid hormone level or activity). Normal calcium with an elevated urea nitrogen value indicates possible hyperparathyroidism (primary or secondary). Normal calcium with decreased albumin value is an indication of hypercalcemia (high calcium levels). The most common cause of hypocalcemia (low calcium levels) is hypoalbuminemia. The most common causes of hypercalcemia are hyperparathyroidism and cancer (with or without bone metastases).

**INDICATIONS:**
- Detect parathyroid gland loss after thyroid or other neck surgery, as indicated by decreased levels
- Evaluate cardiac arrhythmias and coagulation disorders to determine if altered serum calcium level is contributing to the problem
- Evaluate the effects of various disorders on calcium metabolism, especially diseases involving bone
- Monitor the effectiveness of therapy being administered to correct abnormal calcium levels, especially calcium deficiencies
- Monitor the effects of renal failure and various drugs on calcium levels

**RESULT:**

**Increased in:**
- Acidosis (Exchange of electrolytes is affected. Long-standing acidosis can result in osteoporosis and release of calcium into circulation)
- Acromegaly (Vitamin D metabolism is affected, resulting in increased calcium)
- Addison’s disease (Related to adrenal gland dysfunction; decreased blood volume and dehydration occur in the absence of aldosterone)
- Cancers (bone, Burkitt’s lymphoma, Hodgkin’s lymphoma, leukemia, myeloma, and metastases from other organs)
- Dehydration (Decrease in fluid portion of blood causes an overall increase in most constituents)
- Hyperparathyroidism (PTH and vitamin D increase circulating calcium levels)
- Idiopathic hypercalcemia of infancy
- Lung disease (tuberculosis, histoplasmosis, coccidioidomycosis, berylliosis) (Macrophages in the epithe-lium interfere with Vitamin D regulation by converting it to its active form. Vitamin D increases circulating calcium levels)
Malignant disease without bone involvement (Some cancers, e.g., squamous cell carcinoma of the lung and kidney cancer, produce PTH-related peptide that increases calcium levels)

Milk-alkali syndrome (Burnett’s syndrome) (Excessive intake of calcium-containing milk or antacids can increase calcium levels)

Paget’s disease (Calcium is released from bone)

Pheochromocytoma (Hyperparathyroidism related to MEN 2A syndrome associated with some pheochromocytomas; PTH increases calcium levels)

Polycythemia vera (Related to dehydration; decreased blood volume due to excessive production of red blood cells)

Renal transplant (Imbalances in electrolytes is a common post-transplant issue)

Sarcoidosis (Macrophages in the granulomas interfere with vitamin D regulation by converting it to its active form; vitamin D increases circulating calcium levels)

Thyrotoxicosis (Related to increased bone turnover and release of calcium into the blood)

Vitamin D toxicity (Vitamin D increases circulating calcium levels)

Decreased in:

Acute pancreatitis (Complication of pancreatitis related to hypoalbuminemia and calcium binding by excessive fats)

Alcoholism (Related to insufficient nutrition)

Alkalosis (Increased blood pH causes intracellular uptake of calcium to increase)

Chronic renal failure (Related to decreased synthesis of vitamin D)

Cystinosis (Hereditary disorder of the renal tubules that results in excessive calcium loss)

Hepatic cirrhosis (Related to impaired metabolism of vitamin D and calcium)

Hyperphosphatemia (Phosphorus and calcium have an inverse relationship)

Hypoalbuminemia (Albumin is an important carrier protein)

Hypomagnesemia (Lack of magnesium inhibits PTH and thereby decreases calcium levels)

Hypoparathyroidism (congenital, idiopathic, surgical) (Related to lack of PTH)

Inadequate nutrition

Leprosy (Related to increased bone retention)

Long-term anticonvulsant therapy (These medications block calcium channels and interfere with calcium transport)

Malabsorption (celiac disease, tropical sprue, pancreatic insufficiency) (Insufficient absorption)

Massive blood transfusion (Citrate preservative in blood product chelates or binds calcium and removes it from circulation)

Neonatal prematurity

Osteomalacia (advanced) (Bone loss is so advanced there is little calcium remaining to be released into circulation)

Renal tubular disease (Related to decreased synthesis of vitamin D)

Vitamin D deficiency (rickets) (Lack of vitamin D results in decreased calcium metabolism)

**CRITICAL VALUES:**

Less than 7 mg/dL

Greater than 12 mg/dL (some patients can tolerate higher concentrations)

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms.
Observe the patient for symptoms of critically decreased or elevated calcium levels. Hypocalcemia is evidenced by convulsions, arrhythmias, changes in electrocardiogram (ECG) in the form of prolonged ST segment and Q-T interval, facial spasms (positive Chvostek’s sign), tetany, muscle cramps, numbness in extremities, tingling, and muscle twitching (positive Trousseau’s sign). Possible interventions include seizure precautions, increased frequency of ECG monitoring, and administration of calcium or magnesium.

Severe hypercalcemia is manifested by polyuria, constipation, changes in ECG (shortened ST segment), lethargy, muscle weakness, apathy, anorexia, headache, and nausea and ultimately may result in coma. Possible interventions include the administration of normal saline and diuretics to speed up excretion or administration of calcitonin or steroids to force the circulating calcium into the cells.

**INTERFERING FACTORS:**
- Drugs that may increase calcium levels include anabolic steroids, some antacids, calcitriol, calcium salts, danazol, diuretics (long-term), ergocalciferol, isotretinoin, lithium, oral contraceptives, parathyroid extract, parathyroid hormone, prednisone, progesterone, tamoxifen, vitamin A, and vitamin D.
- Drugs that may decrease calcium levels include albuterol, alprostadil, aminoglycosides, anticonvulsants, calcitonin, diuretics (initially), gastrin, glucagon, glucocorticoids, glucose, insulin, laxatives (excessive use), magnesium salts, methicillin, phosphates, plicamycin, sodium sulfate (given IV), tetracycline (in pregnancy), trazodone, and viomycin.
- Calcium exhibits diurnal variation; serial samples should be collected at the same time of day for comparison.

- Venous hemostasis caused by prolonged use of a tourniquet during venipuncture can falsely elevate calcium levels.
- Patients on ethylenediaminetetraacetic acid (EDTA) therapy (chelation) may show falsely decreased calcium values.
- Hemolysis and icterus cause false-positive results because of interference from biological pigments.
- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is present in the IV solution, falsely increasing the result.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to investigate various conditions indicated by abnormally increased or decreased calcium levels.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular, gastrointestinal, genitourinary, hematopoietic, hepatobiliary, and musculoskeletal systems, as well as results of previously performed laboratory tests, diagnostic, and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture. Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient. Nutritional considerations: Patients with abnormal calcium values should be informed that daily intake of calcium is important even though body stores in the bones can be called on to supplement circulating levels. Dietary calcium can be obtained from animal or plant sources. Milk and milk products, sardines, clams, oysters, salmon, rhubarb, spinach, beet greens, broccoli, kale, tofu, legumes, and fortified orange juice are high in calcium. Milk and milk products also contain vitamin D and lactose, which assist calcium absorption. Cooked vegetables yield more absorbable calcium than raw vegetables. Patients should be informed of the substances that can inhibit calcium absorption by irreversibly binding to some of the calcium, making it unavailable for absorption, such as oxalates, which naturally occur in some vegetables (e.g., beet greens, collards, leeks, okra, parsley, quinoa, spinach, Swiss chard) and are found in tea; phytic acid, found in some cereals (e.g., wheat bran, wheat germ); phosphoric acid, found in dark cola; and insoluble dietary fiber (in excessive amounts). Excessive protein intake can also negatively affect calcium absorption, especially if it is combined with foods high in phosphorus and in the presence of a reduced dietary calcium intake.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ACTH, albumin, aldosterone, ALP, biopsy bone marrow, BMD, bone scan, calcitonin, calcium ionized, urine calcium, calculus kidney stone analysis, catecholamines, chloride, collagen cross-linked telopeptides, complete blood count, CT pelvis, CT spine, cortisol, CK and isoenzymes, DHEA, fecal fat, glucose, HVA, magnesium, metanephrines, osteocalcin, PTH, phosphorus, potassium, protein total, radiography bone, renin, sodium, thyroid scan, thyroxine, US thyroid and parathyroid, UA, and vitamin D.
- Refer to the Cardiovascular, Gastrointestinal, Genitourinary, Hematopoietic, Hepatobiliary, and Musculoskeletal System tables at the back of the book for related tests by body system.
SYNONYM/ACRONYM: free calcium, unbound calcium, Ca++, Ca²⁺.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Specimen should be transported tightly capped and remain unopened until testing. Exposure of serum to room air changes the pH of the specimen due to the release of carbon dioxide and can cause erroneous results.

REFERENCE VALUE: (Method: Ion-selective electrode)

DESCRIPTION: Calcium is the most abundant cation in the body and participates in almost all vital body processes (see other calcium monographs). Circulating calcium is found in the free or ionized form; bound to organic anions such as lactate, phosphate, or citrate; and bound to proteins such as albumin. Ionized calcium is the physiologically active form of circulating calcium. About half of the total amount of calcium circulates as free ions that participate in blood coagulation, neuromuscular conduction, intracellular regulation, glandular secretion, and control of skeletal and cardiac muscle contractility. Calcium levels are regulated largely by the parathyroid glands and by vitamin D. Compared to total calcium level, ionized calcium is a better measurement of calcium metabolism. Ionized calcium levels are not influenced by protein concentrations, as seen in patients with chronic renal failure, nephrotic syndrome, malabsorption, and multiple myeloma. Levels are also not affected in patients with metabolic acid-base balance disturbances. Elevations in ionized calcium may be seen when the total calcium is normal. Measurement of ionized calcium is useful to monitor patients undergoing cardiothoracic surgery or organ transplantation. It is also useful in the evaluation of patients in cardiac arrest.
INDICATIONS:
• Detect ectopic parathyroid hormone–producing neoplasms
• Evaluate the effect of protein on calcium levels
• Identify individuals with hypocalcemia
• Identify individuals with toxic levels of vitamin D
• Investigate suspected hyperparathyroidism
• Monitor patients with renal failure or organ transplantation, in whom secondary hyperparathyroidism may be a complication
• Monitor patients with sepsis or magnesium deficiency

RESULT:
Increased in:
• Hyperparathyroidism (Related to increased PTH)
• Parathyroid hormone–producing neoplasms (PTH increases calcium levels)
• Vitamin D toxicity (Increases absorption of calcium)

Decreased in:
• Burns, severe (Related to increased amino acid release)
• Hypoparathyroidism (primary) (Related to decreased PTH)
• Magnesium deficiency (Inhibits release of PTH)
• Multiple organ failure
• Pancreatitis (Associated with saponification or binding of calcium to fats in tissue surrounding the pancreas)
• The postdialysis period (Result of low-calcium dialysate administration)
• The postsurgical period (i.e., major surgeries) (Related to decreased PTH)
• The post-transfusion period (Result of the use of citrated blood product preservative (calcium chelator))
• Premature infants with hypoproteinemia and acidosis (Related to alterations in transport protein levels)
• Pseudohypoparathyroidism (Related to decreased PTH)
• Sepsis (Related to decreased PTH)
• Trauma (Related to decreased PTH)
• Vitamin D deficiency (Decreased absorption of calcium)

CRITICAL VALUES:
Less than 3.2 mg/dL
Greater than 6.2 mg/dL
Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms.

Observe the patient for symptoms of critically decreased or elevated calcium levels. Hypocalcemia is evidenced by convulsions, arrhythmias, changes in electrocardiogram (ECG) in the form of prolonged ST segment and Q-T interval, facial spasms (positive Chvostek’s sign), tetany, muscle cramps, numbness in extremities, tingling, and muscle twitching (positive Trousseau’s sign). Possible interventions include seizure precautions, increased frequency of ECG monitoring, and administration of calcium or magnesium.

Severe hypercalcemia is manifested by polyuria, constipation, changes in ECG (shortened ST segment), lethargy, muscle weakness, apathy, anorexia, headache, and nausea, and ultimately may result in coma. Possible interventions include the administration of normal saline and diuretics to speed up excretion or administration of calcitonin or steroids to force the circulating calcium into the cells.

INTERFERING FACTORS:
• Drugs that may increase calcium levels include antacids (some), calcitriol, and lithium.

Access additional resources at davisplus.fadavis.com
Drugs that may decrease calcium levels include calcitonin, citrates, foscarnet, and pamidronate (initially).

Calcium exhibits diurnal variation; serial samples should be collected at the same time of day for comparison.

Venous hemostasis caused by prolonged use of a tourniquet during venipuncture can falsely elevate calcium levels.

Patients on ethylenediaminetetraacetic acid (EDTA) therapy (chelation) may show falsely decreased calcium values.

Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is present in the IV solution, falsely increasing the result.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to investigate various conditions indicated by abnormally increased or decreased levels of ionized calcium.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular, gastrointestinal, genitourinary, hematopoietic, hepatobiliary, and musculoskeletal systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that could interfere with test results.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- **Nutritional considerations:** Patients with abnormal calcium values should be informed that daily intake of calcium is important even though body stores in the bones can be called on to supplement circulating levels. Dietary calcium...
can be obtained from animal or plant sources. Milk and milk products, sardines, clams, oysters, salmon, rhubarb, spinach, beet greens, broccoli, kale, tofu, legumes, and fortified orange juice are high in calcium. Milk and milk products also contain vitamin D and lactose, which assist calcium absorption. Cooked vegetables yield more absorbable calcium than raw vegetables. Patients should be informed of the substances that can inhibit calcium absorption by irreversibly binding to some of the calcium, making it unavailable for absorption, such as oxalates, which naturally occur in some vegetables (e.g., beet greens, collards, leeks, okra, parsley, quinoa, spinach, Swiss chard) and are found in tea; phytic acid, found in some cereals (e.g., wheat bran, wheat germ); phosphoric acid, found in dark cola; and insoluble dietary fiber (in excessive amounts). Excessive protein intake can also negatively affect calcium absorption, especially if it is combined with foods high in phosphorus and in the presence of a reduced dietary calcium intake.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include albumin, ALP, calcitonin, calcium, calculus kidney stone panel, gastrin and gastrin stimulation, magnesium, PTH, parathyroid scan, phosphorus, potassium, protein total, sodium, thyroglobulin, US thyroid and parathyroid, UA, and vitamin D.
- Refer to the Cardiovascular, Gastrointestinal, Genitourinary, Hematopoietic, Hepatobiliary, and Musculoskeletal System tables at the back of the book for related tests by body system.

**SYNONYM/ACRONYM:** N/A

**SPECIMEN:** Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

**REFERENCE VALUE:** (Method: Spectrophotometry)

*Values depend on diet. Average daily intake of calcium: 600–800 mg/24 hr.
**DESCRIPTION:** Regulating electrolyte balance is a major function of the kidneys. In normally functioning kidneys, urine levels increase when serum levels are high and decrease when serum levels are low to maintain homeostasis. Analyzing urinary electrolyte levels can provide important clues to the functioning of the kidneys and other major organs. Tests for calcium in urine usually involve timed urine collections during a 12- or 24-hr period. Measurement of random specimens may also be requested. Urinary calcium excretion may also be expressed as calcium-to-creatinine ratio: In a healthy individual with constant muscle mass, the ratio is less than 0.14.

**INDICATIONS:**
- Assist in establishing the presence of kidney stones
- Evaluate bone disease
- Evaluate dietary intake and absorption
- Evaluate renal loss
- Monitor patients on calcium replacement

**RESULT:**

*Increased in:*
- Acromegaly (Vitamin D metabolism is affected, resulting in increased calcium)
- Diabetes (Related to increased loss from damaged kidneys)
- Fanconi’s syndrome (Hereditary or acquired disorder of the renal tubules that results in excessive calcium loss)
- Glucocorticoid excess (Glucocorticoids decrease the gastrointestinal absorption of calcium and increase urinary excretion)
- Hepatolenticular degeneration (Wilson’s disease) (Related to renal damage and excessive electrolyte loss)
- Hyperparathyroidism (Increased levels of PTH result in increased calcium levels)
- Hyperthyroidism (Increased bone turnover; excess circulating calcium is excreted by the kidneys)
- Idiopathic hypercalciuria
- Immobilization (Related to disruption in calcium homeostasis and bone loss)
- Kidney stones (Excessive urinary calcium contributes to the formation of kidney stones)
- Leukemia and lymphoma (some instances)
- Myeloma (Calcium is released from damaged bone; excess circulating calcium is excreted by the kidneys)
- Neoplasm of the breast or bladder (Some cancers secrete PTH or PTH-related peptide that increases calcium levels)
- Osteitis deformans (Calcium is released from damaged bone; excess circulating calcium is excreted by the kidneys)
- Osteolytic bone metastases (carcinoma, sarcoma) (Calcium is released from damaged bone; excess circulating calcium is excreted by the kidneys)
- Osteoporosis (Calcium is released from damaged bone; excess circulating calcium is excreted by the kidneys)
- Paget’s disease
- Renal tubular acidosis (Calcium is released from damaged bone; excess circulating calcium is excreted by the kidneys)
- Sarcoidosis (Macrophages in the granulomas interfere with Vitamin D regulation by converting it to its active form.)
Vitamin D increases circulating calcium levels and excess is excreted by the kidneys)
• Schistosomiasis
• Thyrotoxicosis (Increased bone turnover; excess circulating calcium is excreted by the kidneys)
• Vitamin D intoxication (Increases calcium metabolism; excess is excreted by the kidneys)

Decreased in:
• Hypocalcemia (other than renal disease)
• Hypocalciuric hypercalcemia (familial, nonfamilial)
• Hypoparathyroidism (PTH instigates release of calcium; if PTH levels are low, calcium levels will be decreased)
• Hypothyroidism
• Malabsorption (celiac disease, tropical sprue)
• Malignant bone neoplasm
• Nephrosis and acute nephritis (Related to decreased synthesis of vitamin D)
• Osteoblastic metastases
• Osteomalacia (Related to vitamin D deficiency)
• Pre-eclampsia
• Pseudohypoparathyroidism
• Renal osteodystrophy
• Rickets (Deficiency in vitamin D results in decreased calcium levels)
• Vitamin D deficiency (Deficiency in vitamin D results in decreased calcium levels)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that can increase urine calcium levels include acetazolamide, ammonium chloride, asparaginase, calcitonin, calcitriol, corticosteroids, corticotropin, dexamethasone, diuretics (initially), ergocalciferol, ethacrynic acid, mannitol (initially), mercurials, mercaptomerin, mersalyl, nandrolone, parathyroid extract, parathyroid hormone, plicamycin, sodium sulfate, sulfates, triamterene, viomycin, and vitamin D.
• Drugs that can decrease urine calcium levels include angiotensin, bicarbonate, calcitonin, citrates, diuretics (chronic), lithium, neomycin, oral contraceptives, and spironolactone.
• Failure to collect all the urine and store the specimen properly during the 24-hr test period invalidates the results.

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to indicate sufficiency of dietary calcium intake and rate of absorption. Urine calcium levels are also used to assess bone resorption, renal stones, and renal loss of calcium.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s endocrine, genitourinary, and musculoskeletal systems and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.
• Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological

Access additional resources at davisplus.fadavis.com
support before, during, and after
the procedure.

- Usually a 24-hr time frame for urine
collection is ordered. Inform the patient
that all urine must be saved during that
24-hr period. Instruct the patient not to
void directly into the laboratory collec-
tion container. Instruct the patient to
avoid defecating in the collection
device and to keep toilet tissue out of
the collection device to prevent con-
tamination of the specimen. Place a
sign in the bathroom to remind the
patient to save all urine.

- Instruct the patient to void all urine into
the collection device and then to pour
the urine into the laboratory collection
container. Alternatively, the specimen
can be left in the collection device for a
health care staff member to add to the
laboratory collection container.

- There are no fluid or medication
restrictions unless by medical direction.

- Instruct the patient to follow a normal
calcium diet for at least 4 days
before test. Protocols may vary from
facility to facility.

**INTRATEST:**

- Ensure that the patient has complied
with dietary restrictions; assure that
a normal calcium diet has been
followed for at least 4 days prior to
the procedure.

- If the patient has a history of allergic
reaction to latex, avoid the use of
equipment containing latex.

- Instruct the patient to cooperate fully
and to follow directions.

- Observe standard precautions, and
follow the general guidelines in
Appendix A. Positively identify the
patient, and label the appropriate col-
lection container with the correspon-
ding patient demographics, date, and
time of collection.

**Random Specimen (Collect in
Early Morning):**

- Obtain urine specimen in a properly
labeled plastic collection container and
immediately transport urine. If an
indwelling catheter is in place, it may
be necessary to clamp off the catheter
for 15 to 30 min before specimen col-
lection. Cleanse specimen port with
antiseptic swab, and then aspirate
5 mL of urine with a 21- to 25-gauge

- Needle and syringe. Transfer urine to a
plastic container.

**Timed Specimen:**

- Obtain a clean 3-L urine specimen
container, toilet-mounted collection
device, and plastic bag (for transport of
the specimen container). The speci-
men must be refrigerated or kept on
ice throughout the collection period. If
an indwelling urinary catheter is in
place, the drainage bag must be kept
on ice.

- Begin the test between 6 and 8 a.m., if
possible. Collect first voiding and dis-
card. Record the time the specimen
was discarded as the beginning of the
timed collection period. The next morn-
ing, ask the patient to void at the same
time the collection was started, and
add this last voiding to the container.

- Urinary output should be recorded
throughout the collection time.

- If an indwelling catheter is in place,
replace the tubing and container
system at the start of the collection
time. Keep the container system on ice
during the collection period or empty
the urine into a larger container
periodically during the collection period;
monitor to ensure continued drainage,
and conclude the test the next morning
at the same hour the collection began.

- At the conclusion of the test, compare
the quantity of urine with the urinary
output record for the collection; if the
specimen contains less than the
recorded output, some urine may have
been discarded, invalidating the test.

- Include on the collection container’s
label the amount of urine collected and
test start and stop times. Promptly
transport the specimen to the labora-
tory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to
the requesting health care provider
(HCP), who will discuss the results with
the patient.

- Instruct the patient to resume usual
diet as directed by the HCP.

**Nutritional considerations:** Increased urine
calcium levels may be associated with
kidney stones. Educate the patient, if
appropriate, as to the importance of
drinking a sufficient amount of water
when kidney stones are suspected.
CALCULUS, KIDNEY STONE PANEL

- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include ACTH, albumin, aldosterone, ALP, biopsy bone marrow, BMD, bone scan, calcitonin, calcium, ionized, calculus kidney stone analysis, catecholamines, chloride, collagen, cross-linked telopeptides, complete blood count, CT pelvis, CT spine, cortisol, CK and isoenzymes, DHEA, fecal fat, glucose, HVA, magnesium, metanephrines, osteocalcin, oxalate, PTH, phosphorus, potassium, protein total, radiography bone, renin, sodium, thyroid scan, thyroxine, US thyroid and parathyroid, UA, uric acid, and vitamin D.
- Refer to the Endocrine, Genitourinary, and Musculoskeletal System tables at the end of the book for related tests by body system.

SYNONYM/ACRONYM: Kidney stone analysis, nephrolithiasis analysis.

SPECIMEN: Kidney stones.

REFERENCE VALUE: (Method: Infrared spectrometry) None detected.

RESULT:
- Positive findings in:
  - Presence of renal calculi
- Negative findings in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs and substances that may increase the formation of urine calculi include probenecid and vitamin D.
- Adhesive tape should not be used to attach stones to any transportation or collection container, because the adhesive interferes with infrared spectrometry.

DESCRIPTION: Renal calculi (kidney stones) are formed by the crystallization of calcium oxalate (most common), magnesium ammonium phosphate, calcium phosphate, uric acid, and cystine. Formation of stones may be due to reduced urine flow and excessive amounts of the previously mentioned insoluble substances. The presence of stones is confirmed by diagnostic visualization or passing of the stones in the urine. The chemical nature of the stones is confirmed qualitatively.

INDICATIONS: Identify substances present in renal calculi

Access additional resources at davisplus.fadavis.com
PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to identify the presence of kidney stones.
- Obtain a history of the patient’s complaints, especially hematuria, recurrent urinary tract infection, and abdominal pain. Also, obtain a list of known allergens.
- Obtain a history of the patient’s genitourinary system and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain and explain that there may be some discomfort during the procedure.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.
- The patient presenting with symptoms indicating the presence of kidney stones may be provided with a device to strain the urine. The patient should be informed to transfer any particulate matter remaining in the strainer into the specimen collection container provided. Stones removed by the health care provider (HCP) should be placed in the appropriate collection container.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Inform the patient with kidney stones that the likelihood of recurrence is high. Educate the patient regarding risk factors that contribute to the likelihood of kidney stone formation, including family history, osteoporosis, urinary tract infections, gout, magnesium deficiency, Crohn’s disease with prior resection, age, gender (males are two to three times more likely to develop stones than females), and climate.
- Dietary considerations: Nutritional therapy is indicated for individuals identified as being at high risk for developing kidney stones. Educate the patient that diets rich in protein, salt, and oxalates increase the risk of stone formation. Adequate fluid intake should be encouraged.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Follow-up testing of urine may be requested, but usually not for 1 mo after the stones have passed or been removed. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include CT abdomen, calcium, creatinine clearance, culture bacterial urine, cystoscopy, IVP, KUB, magnesium, oxalate, phosphorus, renogram, retrograde ureteropyelography, US kidney, uric acid, and UA.
- Refer to the Genitourinary System table at the end of the book for related tests by body system.
Capsule Endoscopy

SYNONYM/ACRONYM: Pill GI endoscopy.

AREA OF APPLICATION: Esophagus, stomach, upper duodenum, and small bowel.

CONTRAST: None.

DESCRIPTION: This outpatient procedure involves ingesting a small (size of a large vitamin pill) capsule that is wireless and contains a small video camera that will pass naturally through the digestive system while taking pictures of the intestine. The capsule is 11 mm by 30 mm and contains a camera, light source, radio transmitter, and battery. The patient swallows the capsule, and the camera takes and transmits two images per second. The images are transmitted to a recording device, which saves all images for review later by a health care practitioner (HCP). This device is approximately the size of a personal compact disc player. The recording device is worn on a belt around the patient’s waist, and the video images are transmitted to aerials taped to the body and stored on the device. After 8 hr, the device is removed and returned to the HCP for processing. Thousands of images are downloaded onto a computer for viewing by a HCP specialist. The capsule is disposable and will be excreted naturally in the patient’s bowel movements. In the rare case that it is not excreted naturally, it will need to be removed endoscopically or surgically.

INDICATIONS:
- Assist in differentiating between benign and neoplastic tumors
- Detect gastric or duodenal ulcers
- Detect gastrointestinal tract (GI) inflammatory disease
- Determine the presence and location of GI bleeding and vascular abnormalities
- Evaluate the extent of esophageal injury after ingestion of chemicals
- Evaluate stomach or duodenum after surgical procedures
- Evaluate suspected gastric obstruction
- Identify Crohn’s disease, infectious enteritis, and celiac sprue
- Identify source of chronic diarrhea
- Investigate the cause of abdominal pain, celiac syndrome, and other malabsorption syndromes

RESULT:

Normal findings in:
- Esophageal mucosa is normally yellow-pink. At about 9 in. from the incisor teeth, a pulsation indicates the location of the aortic arch. The gastric mucosa is orange-red and contains rugae. The proximal duodenum is reddish and contains a few longitudinal folds, whereas the distal duodenum has circular folds lined with villi. No abnormal structures or functions are observed in the esophagus, stomach, or duodenum.
Abnormal findings in:
• Achalasia
• Acute and chronic gastric and duodenal ulcers
• Crohn’s disease, infectious enteritis, and celiac sprue
• Diverticular disease
• Duodenal cancer, diverticula, and ulcers
• Duodenitis
• Esophageal or pyloric stenosis
• Esophageal varices
• Esophagitis or strictures
• Gastric cancer, tumors, and ulcers
• Gastritis
• Hiatal hernia
• Mallory-Weiss syndrome
• Perforation of the esophagus, stomach, or small bowel
• Polyps
• Small bowel tumors
• Strictures
• Tumors (benign or malignant)

Factors that may impair clear imaging:
• Gas or feces in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study
• Retained barium from a previous radiological procedure

Other considerations:
• The patient should not be near any electromagnetic source, such as magnetic resonance imaging (MRI) or amateur (ham) radio equipment.
• Undergoing an MRI during the procedure may result in serious damage to the patient’s intestinal tract or abdomen. The patient should contact his or her HCP for evaluation prior to any other procedure.
• Delayed capsule transit times may be a result of narcotic use, somatostatin use, gastroparesis, or psychiatric illness.

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients who have had surgery involving the stomach or duodenum, which can make locating the duodenal papilla difficult
• Patients with a bleeding disorder
• Patients with unstable cardiopulmonary status, blood coagulation defects, or cholangitis, unless the patient received prophylactic antibiotic therapy before the test (otherwise the examination must be rescheduled)
• Patients with unstable cardiopulmonary status, blood coagulation defects, known aortic arch aneurysm, large esophageal Zenker’s diverticulum, recent GI surgery, esophageal varices, or known esophageal perforation

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses the GI tract.
• Obtain a history of the patient’s complaints including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, and dyes.
• Obtain a history of results of the patient’s previously performed laboratory tests and diagnostic and surgical procedures.
• Ensure that this procedure is performed before an upper GI series or barium swallow.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
• Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical
direction for the appropriate number of days prior to a surgical procedure. Note time and date of last dose.
Review the procedure with the patient. Address concerns about pain and explain that no pain will be experienced during the procedure. Inform the patient that the procedure is begun in a GI lab or office, usually by a HCP or support staff, and that it takes approximately 30 to 60 min to begin the procedure.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
Instruct the patient to stop taking medications that have a coating effect, such as sucralfate and Pepto-Bismol, 3 days before the procedure.
Instruct the patient to abstain from the use of tobacco products for 24 hr prior to the procedure.
Instruct the patient to start a liquid diet on the day before the procedure. From 10 p.m. the evening before the procedure, the patient should not eat or drink except for necessary medication with a sip of water. Instruct the patient to take a standard bowel prep the night before the procedure. Protocols may vary from facility to facility.
Instruct the patient not to take any medication for 2 hr prior to the procedure.

**POST-TEST:**
Instruct the patient to resume normal activity, medication, and diet after the test is ended, or as tolerated after the examination, as directed by the HCP.
Instruct the patient to remove the recorder and return it to the HCP.
Patients are asked to verify the elimination of the capsule, but not to retrieve the capsule.
Inform the patient that the capsule is a single-use device that does not harbor any environmental hazards.
Emphasize that any abdominal pain, fever, nausea, vomiting, or difficulty breathing must be immediately reported to the HCP.
A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s health.
lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include barium enema, barium swallow, biopsy intestinal, cancer antigens, colonoscopy, CT abdomen, CT colonoscopy, esophageal monometry, esophagogastroduodenoscopy, fecal analysis, folate, gastric acid emptying scan, gastric acid stimulation test, gastrin, Helicobacter pylori, KUB studies, MRI abdomen, PET pelvis, proctosigmoidoscopy, upper GI and small bowel series, US abdomen, and vitamin B₁₂.

- Refer to the Gastrointestinal System table in the back of the book for related tests by body system.

**SYNONYM/ACRONYM:**

- CO₂ combining power, CO₂, tCO₂.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube, plasma (1 mL) collected in a green-top (lithium or sodium heparin) tube; or whole blood (1 mL) collected in a green-top (lithium or sodium heparin) tube or heparinized syringe.

**REFERENCE VALUE:** (Method: Colorimetry, enzyme assay, or pCO₂ electrode)

**DESCRIPTION:** Serum or plasma carbon dioxide (CO₂) measurement is usually done as part of an electrolyte panel. Total CO₂ (tCO₂) is an important component of the body’s buffering capability, and measurements are used mainly in the evaluation of acid-base balance. It is important to understand the differences...
between tCO₂ (CO₂ content) and CO₂ gas (pCO₂). Total CO₂ reflects the majority of CO₂ in the body, mainly in the form of bicarbonate (HCO₃⁻); is present as a base; and is regulated by the kidneys. CO₂ gas contributes little to the tCO₂ level, is acidic, and is regulated by the lungs (see monograph titled “Blood Gases”).

CO₂ provides the basis for the principal buffering system of the extracellular fluid system, which is the bicarbonate–carbonic acid buffer system. CO₂ circulates in the body either bound to protein or physically dissolved. Constituents in the blood that contribute to tCO₂ levels are bicarbonate (HCO₃⁻), carbamino compounds, and carbonic acid (carbonic acid includes undissociated carbonic acid and dissolved CO₂). Bicarbonate is the second largest group of anions in the extracellular fluid (chloride being the largest group of extracellular anions). tCO₂ levels closely reflect bicarbonate levels in the blood, because 90% to 95% of CO₂ circulates as HCO₃⁻.

**INDICATIONS:**
- Evaluate decreased venous CO₂ in the case of compensated metabolic acidosis
- Evaluate increased venous CO₂ in the case of compensated metabolic alkalosis
- Monitor decreased venous CO₂ as a result of compensated respiratory alkalosis
- Monitor increased venous CO₂ as a result of compensation for respiratory acidosis secondary to significant respiratory system infection or cancer; decreased respiratory rate

**RESULT:**

**Increased in:**
Interpretation requires clinical information and evaluation of other electrolytes
- Acute intermittent porphyria *(Related to severe vomiting associated with acute attacks)*
- Airway obstruction *(Related to impaired elimination from abnormal breathing responses)*
- Asthmatic shock *(Related to impaired elimination from abnormal blood circulation)*
- Bronchitis (chronic) *(Related to impaired elimination from weak breathing responses)*
- Cardiac disorders *(Related to lack of blood circulation)*
- Depression of respiratory center *(Related to impaired elimination from weak breathing responses)*
- Electrolyte disturbance (severe) *(Response to maintain acid-base balance)*
- Emphysema *(Related to impaired elimination from weak breathing responses)*
- Hypothyroidism *(Related to impaired elimination from weak breathing responses)*
- Hypoventilation *(Related to impaired elimination from weak breathing responses)*
- Metabolic alkalosis *(Various causes; excessive vomiting)*
- Myopathy *(Related to impaired ventilation)*
- Pneumonia *(Related to impaired elimination from weak breathing responses)*
- Poliomyelitis *(Related to impaired elimination from weak breathing responses)*
- Respiratory acidosis *(Related to impaired elimination)*

Access additional resources at davisplus.fadavis.com
Tuberculosis (pulmonary)  
(Related to impaired elimination from weak breathing responses)

Decreased in:  
Interpretation requires clinical information and evaluation of other electrolytes  
• Acute renal failure (Response to buildup of ketoacids)  
• Anxiety (Related to hyperventilation; too much CO$_2$ is exhaled)  
• Dehydration (Response to metabolic acidosis that develops)  
• Diabetic ketoacidosis (Response to buildup of ketoacids)  
• Diarrhea (severe) (Acidosis related to loss of base ions like HCO$_3^-$; most of CO$_2$ content is in this form)  
• High fever (Response to neutralize acidosis present during fever)  
• Metabolic acidosis (Response to neutralize acidosis)  
• Respiratory alkalosis (Hyperventilation; too much CO$_2$ is exhaled)  
• Salicylate intoxication (Response to neutralize-related metabolic acidosis)  
• Starvation (Used to neutralize buildup of ketoacids)

CRITICAL VALUES:  
Less than 15 mmol/L  
Greater than 40 mmol/L

Observe the patient for signs and symptoms of excessive or insufficient CO$_2$ levels, and report these findings to the health care provider (HCP). If the patient has been vomiting for several days and is breathing shallowly, or if the patient has had gastric suctioning and is breathing shallowly, this may indicate elevated CO$_2$ levels. Decreased CO$_2$ levels are evidenced by deep, vigorous breathing and flushed skin.

INTERFERING FACTORS:  
• Drugs that may cause an increase in tCO$_2$ levels include acetylsalicylic acid, aldosterone, bicarbonate, carbencillin, carbenoxolone, corticosteroids, dexamethasone, ethacrinic acid, laxatives (chronic abuse), and x-ray contrast agents.  
• Drugs that may cause a decrease in tCO$_2$ levels include acetazolamide, acetylsalicylic acid (initially), amiloride, ammonium chloride, fluorides, metformin, methicillin, nitrofurantoin, NSD 3004 (long-acting carbonic anhydrase inhibitor), paraldehyde, tetracycline, triamterene, and xylitol.

Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results. The specimen should be stored under anaerobic conditions after collection to prevent the diffusion of CO$_2$ gas from the specimen. Falsely decreased values result from uncovered specimens. It is estimated that CO$_2$ diffuses from the sample at the rate of 6 mmol/hr.

PRETEST:  
Inform the patient that the test is used to assess the effect of total carbon dioxide levels on respiratory and metabolic acid-base balance.  
Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.  
Obtain a history of the patient's genitourinary and respiratory systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.  
Note any recent procedures that can interfere with test results.  
Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals.
Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- **Nutritional considerations:** Abnormal CO₂ values may be associated with diseases of the respiratory system. Malnutrition is commonly seen in patients with severe respiratory disease for reasons including fatigue, lack of appetite, and gastrointestinal distress. Research has estimated that the daily caloric intake required for respiration of patients with chronic obstructive pulmonary disease is 10 times higher than that of normal individuals. Adequate intake of vitamins A and C is also important to prevent pulmonary infection and to decrease the extent of lung tissue damage. The importance of following the prescribed diet should be stressed to the patient and/or caregiver.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include anion gap, arterial/alveolar oxygen ratio, biopsy lung, blood gases, chest x-ray, chloride, cold agglutinin titer, culture bacterial blood, culture bacterial sputum, culture mycobacterium, culture viral, cytology sputum, eosinophil count, ESR, gallium scan, gram stain, IgE, ketones, lung perfusion scan, osmolality, phosphorus, plethysmography, pleural fluid analysis, potassium, PFT, pulse oximetry, salicylate, and white blood cell count and differential.
- Refer to the Cardiovascular, Genitourinary, and Respiratory System tables at the end of the book for related tests by body system.
**Carboxyhemoglobin**

**SYNONYM/ACRONYM:** Carbon monoxide, CO, COHb, COH.

**SPECIMEN:** Whole blood (1 mL) collected in a green-top (heparin) or lavender-top (EDTA) tube, depending on laboratory requirement. Specimen should be transported tightly capped (anaerobic) and in an ice slurry if blood gases are to be performed simultaneously. Carboxyhemoglobin is stable at room temperature.

**REFERENCE VALUE:** (Method: Spectrophotometry, co-oximetry)

<tr>
<td>Smokers</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Exogenous carbon monoxide (CO) is a colorless, odorless, tasteless by-product of incomplete combustion derived from the exhaust of automobiles, coal and gas burning, and tobacco smoke. Endogenous CO is produced as a result of red blood cell catabolism. CO levels are elevated in newborns as a result of the combined effects of high hemoglobin turnover and the inefficiency of the infant’s respiratory system. CO binds tightly to hemoglobin with an affinity 250 times greater than oxygen, competitively and dramatically reducing the oxygen-carrying capacity of hemoglobin. The increased percentage of bound CO reflects the extent to which normal transport of oxygen has been negatively affected. Overexposure causes hypoxia, which results in headache, nausea, vomiting, vertigo, collapse, or convulsions. Toxic exposure causes anoxia, increased levels of lactic acid, and irreversibletissue damage, which can result in coma or death. Acute exposure may be evident by a cherry red color to the lips, skin, and nail beds; this observation may not be apparent in cases of chronic exposure. A direct correlation has been implicated between carboxyhemoglobin levels and symptoms of atherosclerotic disease, angina, and myocardial infarction.

**INDICATIONS:**
- Assist in the diagnosis of suspected CO poisoning
- Evaluate the effect of smoking on the patient
- Evaluate exposure to fires and smoke inhalation

**RESULT:**

**Increased in:**
- CO poisoning
- Hemolytic disease (CO released during red blood cell catabolism)
- Tobacco smoking

**Decreased in:** N/A

Women and children may suffer more severe symptoms of carbon monoxide poisoning at lower levels of carbon monoxide than men because women and children usually have lower red blood cell counts.

A possible intervention in moderate CO poisoning is the administration of supplemental oxygen given at atmospheric pressure. In severe CO poisoning, hyperbaric oxygen treatments may be used.

INTERFERING FACTORS:
- Specimen should be collected before administration of oxygen therapy.

Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Explain to the patient or family members that the cause of the headache, vomiting, dizziness, convulsions, or coma could be related to CO exposure. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain to the patient that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- If carboxyhemoglobin measurement will be performed simultaneously with arterial blood gases, prepare an ice slurry in a cup or plastic bag and have it on hand for immediate transport of the specimen to the laboratory.
- There are no food, fluid, or medication restrictions unless by medical direction.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate the extent of carbon monoxide poisoning and toxicity.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s respiratory system and results of previously performed laboratory tests and diagnostic and surgical procedures.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Access additional resources at davisplus.fadavis.com
Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Recognize anxiety related to test results, and be supportive of impaired activity related to fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Educate the patient regarding avoiding gas heaters and indoor cooking fires without adequate ventilation, and the need to have gas furnaces checked yearly for CO leakage. Inform the patient of smoking cessation programs, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include angiography pulmonary, arterial/alveolar oxygen ratio, blood gases, carbon dioxide, complete blood count, lung perfusion scan, lung ventilation scan, plethysmography, and PFT.

Refer to the Respiratory System table at the back of the book for related tests by body system.

SYNONYM/ACRONYM: Carcinoembryonic antigen (CEA), Cancer antigen 125 (CA 125), Cancer antigen 15-3 (CA 15–3), Cancer antigen 19-9 (CA 19-9), Cancer antigen 27.29 (CA 27.29).

SPECIMEN: Serum (1 mL) collected in a red-top tube. Care must be taken to use the same assay method if serial measurements are to be taken.

**DESCRIPTION:** Carcinoembryonic antigen (CEA) is a glycoprotein normally produced only during early fetal life and rapid multiplication of epithelial cells, especially those of the digestive system. CEA also appears in the blood of chronic smokers. Although the test is not diagnostic for any specific disease and is not useful as a screening test for cancer, it is very useful for monitoring response to therapy in breast, liver, colon, and gastrointestinal cancer. Serial monitoring is also a useful indicator of recurrence or metastasis in colon or liver carcinoma.

CA 125, a glycoprotein present in normal endometrial tissue, appears in the blood when natural endometrial protective barriers are destroyed, as occurs in cancer or endometriosis. Persistently rising levels indicate a poor prognosis, but absence of the tumor marker does not rule out tumor presence. Levels may also rise in pancreatic, liver, colon, breast, and lung cancers. CA 125 is most useful in monitoring the progression or recurrence of known ovarian cancer. It is not useful as a screening test when used alone.
CA 15-3 monitors patients for recurrence or metastasis of breast carcinoma.
CA 19-9 is a carbohydrate antigen used for post-therapeutic monitoring of patients with gastrointestinal, pancreatic, liver, and colorectal cancer.
CA 27.29 is a glycoprotein product of the muc-1 gene. It is most useful as a serial monitor for response to therapy or recurrence of breast carcinoma.

**INDICATIONS:**

**CEA**
- Determine stage of colorectal cancer and test for recurrence or metastasis
- Monitor response to treatment of breast and gastrointestinal cancers

**CA 125**
- Assist in the diagnosis of carcinoma of the cervix and endometrium
- Assist in the diagnosis of ovarian cancer
- Monitor response to treatment of ovarian cancer

**CA 15-3 and CA 27.29**
- Monitor recurrent carcinoma of the breast

**CA 19-9**
- Monitor effectiveness of therapy
- Monitor gastrointestinal, head and neck, and gynecological carcinomas
- Predict recurrence of cholangiocarcinoma
- Predict recurrence of stomach, pancreatic, colorectal, gallbladder, liver, and urothelial carcinomas

**RESULT:**

*Increased in:*

**CEA**
- Benign tumors, including benign breast disease

*Decreased in:*

**CEA**
- Chronic tobacco smoking
- Cirrhosis
- Colorectal, pulmonary, gastric, pancreatic, breast, head or neck, esophageal, ovarian, or prostate cancer
- Inflammatory bowel disease
- Pancreatitis
- Radiation therapy (transient)

**CA 125**
- Breast, colon, endometrial, lung, ovarian, and pancreatic cancer
- Endometriosis
- First-trimester pregnancy
- Menses
- Ovarian abscess
- Pelvic inflammatory disease
- Peritonitis

**CA 15-3 and CA 27.29**
- Recurrence of breast carcinoma

**CA 19-9**
- Gastrointestinal, head and neck, and gynecologic carcinomas
- Recurrence of stomach, pancreatic, colorectal, gallbladder, liver, and urothelial carcinomas
- Recurrence of cholangiocarcinoma

*Decreased in:*

- Effective therapy or removal of the tumor

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when radioimmunoassay is the test method.

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
Inform the patient that the test is used to monitor the progress of various types of cancer and evaluate the response to therapy.

Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient’s gastrointestinal, immune, and reproductive systems, as well as results of previously performed laboratory tests, diagnostic, and surgical procedures.

Note any recent radiology procedures that can interfere with test results.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Determine if the patient smokes, because smokers may have false elevations of CEA.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A report of the results will be sent to the requesting health care provider (HCP), who will discuss them with the patient.

Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Cancer Association (www.cancer.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that the test may be repeated periodically to monitor response to therapy. Instruct the patient in the importance of continuing scheduled therapy or follow-up visits. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include barium enema, biopsy breast, biopsy cervical, biopsy intestinal, biopsy liver, capsule endoscopy, colonoscopy, colposcopy, fecal analysis, HCG, liver & spleen scan, MRI breast, MRI liver, mammogram, stereotactic breast biopsy, proctosigmoidoscopy, radiofrequency ablation liver, US breast, and US liver.

Refer to the Gastrointestinal, Immune, and Reproductive System tables at the back of the book for related tests by body system.
SYNONYM/ACRONYM: Epinephrine, norepinephrine, dopamine.

SPECIMEN: Plasma (2 mL) collected in green-top (heparin) tube. Urine (25 mL) from a timed specimen collected in a clean, plastic, amber collection container with 6N hydrochloric acid as a preservative.

REFERENCE VALUE: (Method: High-performance liquid chromatography)

DESCRIPTION: Catecholamines are produced by the chromaffin tissue of the adrenal medulla. They also are found in sympathetic nerve endings and in the brain. The major catecholamines are epinephrine, norepinephrine, and dopamine. They prepare the body for the fight-or-flight stress response, help regulate metabolism, and are excreted from the body by the kidneys. Levels are affected by diurnal variations, fluctuating in response to stress, postural changes, diet, smoking, drugs, and temperature changes. As a result, blood measurement is not as reliable as a 24-hr timed urine test. For test results to be valid, all of the previously mentioned environmental variables must be controlled when the test is performed. Results of blood specimens are most reliable when the specimen is collected during a hypertensive episode. Catecholamines are measured when there is high suspicion of pheochromocytoma but urine results are normal or borderline. Use of a clonidine suppression test with measurement of plasma catecholamines may be requested. Failure to suppress production of catecholamines after administration of clonidine supports the diagnosis of pheochromocytoma. Elevated homovanillic acid levels rule out pheochromocytoma because this tumor primarily secretes epinephrine. Elevated catecholamines without hypertension suggest neuroblastoma or ganglioneuroma. Findings should be compared with metanephrines and vanillylmandelic acid, which are the metabolites of epinephrine and norepinephrine. Findings should also be compared with homovanillic acid, which is the product of dopamine metabolism.

INDICATIONS:

- Assist in the diagnosis of neuroblastoma, ganglioneuroma, or dysautonomia
- Assist in the diagnosis of pheochromocytoma
- Evaluate acute hypertensive episode
- Evaluate hypertension of unknown origin
- Screen for pheochromocytoma among family members with an autosomal dominant inheritance pattern for Lindau–von Hippel disease or multiple endocrine neoplasia

RESULT:

**Increased in:**

- Diabetic acidosis (epinephrine and norepinephrine)
- Ganglioblastoma (epinephrine, slight increase; norepinephrine, large increase)
- Ganglioneuroma (all are increased; norepinephrine, largest increase)
- Hypothyroidism (epinephrine and norepinephrine)
- Long-term manic-depressive disorders (epinephrine and norepinephrine)
- Myocardial infarction (epinephrine and norepinephrine)
- Neuroblastoma (all are increased; norepinephrine and dopamine, largest increase)
- Pheochromocytoma (epinephrine, continuous or intermittent increase; norepinephrine, slight increase)
- Shock (epinephrine and norepinephrine)
- Strenuous exercise (epinephrine and norepinephrine)
Decreased in:
- Autonomic nervous system dysfunction (norepinephrine)
- Orthostatic hypotension (norepinephrine)
- Parkinson’s disease (dopamine)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs that may increase plasma catecholamine levels include ajmaline, chlorpromazine, cyclopropane, diazoxide, ether, monoamine oxidase inhibitors, nitroglycerin, pentazocine, perphenazine, phenothiazine, promethazine, and theophylline.
- Drugs that may decrease plasma catecholamine levels include clonidine, metyrosine, and reserpine.
- Drugs that may increase urine catecholamine levels include acetaminophen, atenolol, dopamine (intravenous), isoproterenol, methyldopa, niacin, nitroglycerin, prochlorperazine, rauwolfia, reserpine, syrosingopine, and theophylline.
- Drugs that may decrease urine catecholamine levels include bretylium tosylate, clonidine, decaborane, guanethidine, guanfacine, methyldopa, ouabain, radiographic substances, and reserpine.
- Stress, hypoglycemia, smoking, and drugs can produce elevated catecholamines.
- Secretion of catecholamines exhibits diurnal variation, with the lowest levels occurring at night.
- Secretion of catecholamines varies during the menstrual cycle, with higher levels excreted during the luteal phase and lowest levels during ovulation.
- Diets high in amines (e.g., bananas, avocados, beer, aged cheese, chocolate, cocoa, coffee, fava beans, grains, tea, vanilla, walnuts, Chianti wine) can produce elevated catecholamine levels.
- Failure to collect all urine and store 24-hr specimen properly will yield a falsely low result.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the blood test is used to diagnose catecholamine-secreting tumors and in the investigation of hypertension; the urine test is used to diagnose pheochromocytoma and in the work-up of neuroblastoma.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the patient’s last menstrual period.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient.

Blood
- Inform the patient that he or she may be asked to keep warm and to rest for 45 to 60 min before the test. Inform the patient that multiple specimens may be required. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
Inform the patient that a saline lock may be inserted before the test because the stress of repeated venipunctures may increase catecholamine levels.

**Urine**
- Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure. Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine over a 24-hr period must be saved; if a preservative has been added to the container, instruct the patient not to discard the preservative. Instruct the patient not to void directly into the laboratory collection container.
- Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom as a reminder to save all urine. Instruct the patient to void all urine into the collection device, then pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

**Blood and Urine**
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to follow a normal-sodium diet for 3 days before testing, abstain from smoking tobacco for 24 hr before testing, and avoid consumption of foods high in amines for 48 hr before testing.
- Instruct the patient to avoid self-prescribed medications for 2 wk before testing (especially appetite suppressants and cold and allergy medications, such as nose drops, cough suppressants, and bronchodilators).
- Instruct the patient to withhold prescribed medication (especially methyldopa, epinephrine, levodopa, and methenamine mandelate) if directed by the health care provider (HCP).
- Instruct the patient to withhold food and fluids for 10 to 12 hr before the test. Protocols may vary from facility to facility.
- Instruct the patient collecting a 24-hr urine specimen to avoid excessive stress and exercise during the test collection period.
- Prior to blood specimen collection, prepare an ice slurry in a cup or plastic bag to have ready for immediate transport of the specimen to the laboratory. Prechill the collection tube in the ice slurry.

**INTRATEST:**
- Ensure that the patient has complied with dietary, medication, and activity restrictions and with pretesting preparations; assure that food and fluids have been restricted for at least 10 to 12 hr prior to the procedure, and that excessive exercise and stress have been avoided prior to the procedure. Instruct the patient to continue to avoid excessive exercise and stress during the 24-hr collection of urine.
- If the patient has a history of allergic reaction to latex, care should be taken to avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date, and time of collection.

**Blood**
- Perform a venipuncture between 6 and 8 a.m.; collect the specimen in a prechilled tube.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
Ask the patient to stand for 10 min, and then perform a second venipuncture and obtain a sample as previously described.

Each sample should be placed in an ice slurry immediately after collection. Information on the specimen labels should be protected from water in the ice slurry by first placing the specimens in a protective plastic bag. Promptly transport the specimens to the laboratory for processing and analysis.

**Urine**

Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.

Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container.

If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.

At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.

**Blood and Urine**

Include on the collection container’s label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A report of the results will be sent to the requesting HCP who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include angiography adrenal, calcitonin, CT renal, HVA, metanephrines, renin, and VMA.

Refer to the Endocrine System table at the end of the book for related tests by body system.
SYNONYM/ACRONYM: T-cell profile.

SPECIMEN: Whole blood (1 mL) collected in green-top (heparin) tube.

REFERENCE VALUE: (Method: flow cytometry)

DESCRIPTION: Enumeration of lymphocytes, identification of cell lineage, and identification of cellular stage of development are used to diagnose and classify malignant myeloproliferative diseases and to plan treatment. T-cell enumeration is also useful in the evaluation and management of immunodeficiency and autoimmune disease. A severely depressed CD4 count is an excellent predictor of imminent opportunistic infection. HIV viral load is another important test used to establish a baseline for viral activity when a person is first diagnosed with HIV. Viral load testing is performed on plasma from a whole blood sample collected in EDTA. Methods commonly used to perform viral load testing include branched DNA (bDNA) or reverse transcriptase PCR (RT-PCR). Results are not interchangeable from method to method. Therefore, it is important to use the same viral load method for serial testing. Baseline and repeat testing for CD4 count and viral load are usually performed 2 to 4 wk apart. The viral load demonstrates how actively the virus is reproducing and helps determine whether treatment is necessary. CD4 count is a reflection of immune status. Public health guidelines recommend that treatment of asymptomatic patients be considered when CD4 count is greater than 350/mm³ and viral load is 55,000 copies/mL or greater (bDNA) or 30,000 copies/mL or greater (RT-PCR); treatment is recommended when the patient is symptomatic regardless of test results or when the patient is asymptomatic and CD4 count is less than 350/mm³ and viral load is detectable. If retroviral therapy is initiated, CD4 counts and viral load studies will be monitored every 3 to 4 mo. Viral mutations occur; increased viral load may indicate resistance to antiviral drugs. Changes in drug therapy may warrant additional viral load studies to verify efficacy of modified therapy.
INDICATIONS:
• Assist in the diagnosis of AIDS and plan treatment
• Evaluate malignant myeloproliferative diseases and plan treatment
• Evaluate thymus-dependent or cellular immunocompetence

RESULT:
Increased in:
• Malignant myeloproliferative diseases (e.g., acute and chronic lymphocytic leukemia, lymphoma)

Decreased in:
• AIDS
• Aplastic anemia
• Hodgkin’s disease

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may increase T-cell count include interferon-γ.
• Drugs that may decrease T-cell count include chlorpromazine and prednisone.
• Specimens should be stored at room temperature.
• Recent radioactive scans or radiation can decrease T-cell counts.
• Values may be abnormal in patients with severe recurrent illness or after recent surgery requiring general anesthesia.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is primarily used to monitor disease progression and effectiveness of retroviral therapy.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s hematopoietic and immune systems and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Note any recent procedures that can interfere with test results.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
• Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:
• If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
• Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
• Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
• Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage. Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
• A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
• Nutritional considerations: As appropriate, stress the importance of good nutrition and suggest that the patient
meet with a nutritional specialist. Stress the importance of following the care plan for medications and follow-up visits. Inform the patient that subsequent requests for follow-up blood work at regular intervals should be anticipated.

Recognize anxiety related to test results, and be supportive of impaired activity related to perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient as to the risk of infection related to immunosuppressed inflammatory response and fatigue related to decreased energy production. Educate the patient regarding access to counseling services.

Sensitivity to social and cultural issues, Counsel the patient, as appropriate, regarding risk of transmission and proper prophylaxis, and reinforce the importance of strict adherence to the treatment regimen, including consultation with a pharmacist.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include biopsy bone marrow, bronchoscopy, complete blood count, culture and smear mycobacteria, culture viral, cytology sputum, gallium scan, HIV-1/HIV-2 antibodies, laparoscopy abdominal, LAP, lymphangiogram, MRI musculoskeletal, mediastinoscopy, \( \beta_2 \)-microglobulin, platelet count, and WBC count and differential.
- Refer to the Hematopoietic and Immune System tables at the end of the book for related tests by body system.

**SYNONYM/ACRONYM:** CSF analysis.

**SPECIMEN:** CSF (1 to 3 mL) collected in three or four separate plastic conical tubes. Tube 1 is used for chemistry and serology testing, tube 2 is used for microbiology, tube 3 is used for cell count, and tube 4 is used for miscellaneous testing.

**REFERENCE VALUE:** (Method: Macroscopic evaluation of appearance; spectrophotometry for glucose, lactic acid, and protein; radioimmunoassay for myelin basic protein; nephelometry for immunoglobulin G [IgG]; electrophoresis for oligoclonal banding; Gram stain, India ink preparation, and culture for microbiology; microscopic examination of fluid for cell count; flocculation for Venereal Disease Research Laboratory [VDRL])

RBC = red blood cell; VDRL = Venereal Disease Research Laboratory; WBC = white blood cell. Color should be assessed after sample is centrifuged.

**DESCRIPTION:** Cerebrospinal fluid (CSF) circulates in the subarachnoid space and has a twofold function: to protect the brain and spinal cord from injury and to transport products of cellular metabolism and neurosecretion. The total volume of CSF is 90 to 150 mL in adults and 60 mL in infants. CSF
CEREBROSPINAL FLUID ANALYSIS

analysis helps determine the presence and cause of bleeding and assists in diagnosing cancer, infections, and degenerative and autoimmune diseases of the brain and spinal cord. Specimens for analysis are most frequently obtained by lumbar puncture and sometimes by ventricular or cisternal puncture. Lumbar puncture can also have therapeutic uses, including injection of drugs and anesthesia.

INDICATIONS:

• Assist in the diagnosis and differentiation of subarachnoid or intracranial hemorrhage
• Assist in the diagnosis and differentiation of viral or bacterial meningitis or encephalitis
• Assist in the diagnosis of diseases such as multiple sclerosis, autoimmune disorders, or degenerative brain disease
• Assist in the diagnosis of neurosyphilis and chronic central nervous system (CNS) infections
• Detect obstruction of CSF circulation due to hemorrhage, tumor, or edema
• Establish the presence of any condition decreasing the flow of oxygen to the brain
• Monitor for metastases of cancer into the CNS
• Monitor severe brain injuries

RESULT:

Increased in:

• Color and appearance (xanthochromia is any pink, yellow, or orange color): bloody—hemorrhage; xanthochromic—old hemorrhage, red blood cell (RBC) breakdown, methemoglobin, bilirubin (greater than 6 mg/dL), increased protein (greater than 150 mg/dL), melanin (meningeal melanomasarcoma), carotene (systemic carotenemia); hazy—meningitis; pink to dark yellow—aspiration of epidural fat; turbid—cells, microorganisms, protein, fat, or contrast medium
• Protein (Related to alterations in blood brain barrier that allow permeability to proteins): meningitis, encephalitis
• Lactic acid (Related to cerebral hypoxia and correlating anaerobic metabolism): bacterial, tubercular, fungal meningitis
• Myelin basic protein (Related to accumulation as a result of nerve sheath demyelination): trauma, stroke, tumor, multiple sclerosis, subacute sclerosing panencephalitis
• IgG and oligoclonal banding (Related to autoimmune or inflammatory response): multiple sclerosis, CNS syphilis, and subacute sclerosing panencephalitis
• Gram stain: meningitis due to Escherichia coli, Streptococcus agalactiae, Streptococcus pneumoniae, Haemophilus influenzae, Mycobacterium avium-intracellulare, Mycobacterium leprae, Mycobacterium tuberculosis, Neisseria meningitidis, Cryptococcus neoformans
• India ink preparation: meningitis due to C. neoformans
• Culture: encephalitis or meningitis due to herpes simplex virus, S. pneumoniae, H. influenzae, N. meningitidis, C. neoformans
• RBC count: hemorrhage
• White blood cell (WBC) count: General increase— injection of contrast media or anticancer drugs in subarachnoid space; CSF infarct; metastatic tumor in contact with CSF; reaction to repeated lumbar puncture

Access additional resources at davisplus.fadavis.com
Elevated WBC count with a predominance of neutrophils indicative of bacterial meningitis
Elevated WBC count with a predominance of lymphocytes indicative of viral, tubercular, parasitic, or fungal meningitis; multiple sclerosis
Elevated WBC count with a predominance of monocytes indicative of chronic bacterial meningitis, amebic meningitis, multiple sclerosis, toxoplasmosis
Increased plasma cells indicative of acute viral infections, multiple sclerosis, sarcoidosis, syphilitic meningoencephalitis, subacute sclerosing panencephalitis, tubercular meningitis, parasitic infections, Guillain-Barré syndrome
Presence of eosinophils indicative of parasitic and fungal infections, acute polyneuritis, idiopathic hypereosinophilic syndrome, reaction to drugs or a shunt in CSF

- VDRL: syphilis
- Positive findings in:
  - Cytology: malignant cells
- Decreased in:
  - Glucose: bacterial and tubercular meningitis

**CRITICAL VALUES:**
- Positive Gram stain, India ink preparation, or culture
- Presence of malignant cells or blasts
- Elevated WBC count
- Glucose greater than 37 mg/dL. Note and immediately report to the health care provider (HCP) any positive or critically increased results and related symptoms.

**INTERFERING FACTORS:**

This procedure is contraindicated for:
- This procedure is contraindicated if infection is present at the needle insertion site.
- It may also be contraindicated in patients with degenerative joint disease or coagulation defects and in patients who are uncooperative during the procedure.
- Use with extreme caution in patients with increased intracranial pressure because overly rapid removal of CSF can result in herniation.

**Other considerations:**
- Drugs that may decrease CSF protein levels include cefotaxime and dexamethasone.
- Interferon-β may increase myelin basic protein levels.
- Drugs that may increase CSF glucose levels include cefotaxime and dexamethasone.
- RBC count may be falsely elevated with a traumatic spinal tap.
- Delays in analysis may present a false positive appearance of xanthochromia due to RBC lysis that begins within 4 hr of a bloody tap.
- Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when radioimmunoassay is the test method.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is primarily used to assist in the differential diagnosis of infection or hemorrhaging in the brain. It is also used in the evaluation of other conditions with significant neuromuscular effects.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- Obtain a history of the patient’s immune and musculoskeletal systems and results of previously performed
laboratory tests and diagnostic and surgical procedures.

- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that the position required may be awkward, but that someone will assist during the procedure. Stress the importance of remaining still and breathing normally throughout the procedure. Inform the patient that specimen collection takes approximately 20 min. Address concerns about pain and explain that a stinging sensation may be felt when the local anesthetic is injected. Instruct the patient to report any pain or other sensations that may require repositioning the spinal needle. Explain that there may be some discomfort during the procedure. Inform the patient the procedure will be performed by a HCP.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions unless by medical direction.

- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependant on the type of anticoagulant. Notify HCP if patient anticoagulant therapy has not been withheld.
- Have emergency equipment readily available.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Collect the specimen in four plastic conical tubes.

Record baseline vital signs.

To perform a lumbar puncture, position the patient in the knee-chest position at the side of the bed. Provide pillows to support the spine or for the patient to grasp. The sitting position is an alternative. In this position, the patient must bend the neck and chest to the knees.

Prepare the site—usually between L3 and L4, or between L4 and L5—with povidone-iodine and drape the area.

A local anesthetic is injected. Using sterile technique, the HCP inserts the spinal needle through the spinous processes of the vertebrae and into the subarachnoid space. The stylet is removed. If the needle is properly placed, CSF drips from the needle.

Attach the stopcock and manometer, and measure initial pressure. Normal pressure for an adult in the lateral recumbent position is 90 to 180 mm H2O; normal pressure for a child age 8 years or younger is 10 to 100 mm H2O. These values depend on the body position and are different in a horizontal or sitting position.

CSF pressure may be elevated if the patient is anxious, holding his or her breath, or tensing muscles. It may also be elevated if the patient’s knees are flexed too firmly against the abdomen. CSF pressure may be significantly elevated in patients with intracranial tumors. If the initial pressure is elevated, the HCP may perform Queckenstedt’s test. To perform this test, pressure is applied to the jugular vein for about 10 sec. CSF pressure usually rises rapidly in response to the occlusion, and then returns to the pretest level within 10 sec after the pressure is released. Sluggish response may indicate CSF obstruction.
Obtain four vials of spinal fluid in separate tubes (1 to 3 mL each), and label them numerically (1–4 or 5) in the order they were filled.

A final pressure reading is taken, and the needle is removed. Clean the puncture site with an antiseptic solution and apply direct pressure with dry gauze to stop bleeding or CSF leakage. Observe puncture site for bleeding, CSF leakage, or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Monitor vital signs and neurologic status and for headache every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

If permitted, administer fluids to replace lost CSF and help prevent or relieve headache—a side effect of lumbar puncture.

Position the patient flat in the supine position with head of bed at not more than a 30° elevation, following the HCP’s instructions. Maintain position for 8 hr. Changing position is acceptable as long as the body remains horizontal.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Provide information regarding vaccine-preventable diseases when indicated (encephalitis, influenza, meningococcal diseases). Answer any questions or address any concerns voiced by the patient or family.

Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include complete blood count, CT brain, culture for appropriate organisms (blood, fungal, mycobacteria, sputum, throat, viral, wound), EMG, evoked brain potentials, gram stain, MRI brain, PET brain, and syphilis serology.

Refer to the Immune and Musculoskeletal System tables at the end of the book for related tests by body system.

**Ceruloplasmin**

**SYNONYM/ACRONYM:** Copper oxidase, Cp.

**DESCRIPTION:** Ceruloplasmin is an \(\alpha_2\)-globulin produced by the liver that binds copper for transport in the blood after it is absorbed from the gastrointestinal system. Decreased production of this globulin causes copper to be deposited in body tissues such as the brain, liver, corneas, and kidneys.

**INDICATIONS:**
- Assist in the diagnosis of Menkes (kinky hair) disease
- Assist in the diagnosis of Wilson’s disease
- Determine genetic predisposition to Wilson’s disease
- Monitor patient response to total parenteral nutrition (hyperalimentation)

**RESULT:**

*Increased in:*
Ceruloplasmin is an acute phase reactant protein and will be increased in many inflammatory conditions including cancer.
- Acute infections
- Biliary cirrhosis
- Cancer of the bone, lung, stomach
- Copper intoxication
- Hodgkin’s disease
- Leukemia
- Pregnancy (last trimester) *(Estrogen increases copper levels)*

*Decreased in:*
- Menkes disease *(Severe X-linked defect causing failed transport to the liver and tissues)*
- Nutritional deficiency of copper
- Wilson’s disease *(Genetic defect causing failed transport to the liver and tissues)*

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase ceruloplasmin levels include anticonvulsants, norethindrone, oral contraceptives, and tamoxifen.
- Drugs that may decrease ceruloplasmin levels include asparaginase and levonorgestrel (Norplant).
- Excessive therapeutic intake of zinc may interfere with intestinal absorption of copper.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used in the evaluation of copper intoxication and liver disease, especially Wilson’s disease.
Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient's hepatobiliary system and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

**Nutritional considerations:** Instruct the patient with copper deficiency to increase intake of foods rich in copper, as appropriate. Organ meats, shellfish, nuts, and legumes are good sources of dietary copper. High intake of zinc, iron, calcium, and manganese interferes with copper absorption. Copper deficiency does not normally occur in adults; however, patients receiving long-term total parenteral nutrition should be evaluated if signs and symptoms of copper deficiency appear, such as jaundice or eye color changes. Kayser-Fleischer rings (green-gold rings) in the cornea and a liver biopsy specimen showing more than 250 mcg of copper per gram confirms Wilson's disease.

Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include biopsy liver, copper, and zinc.

Refer to the Hepatobiliary System table at the end of the book for related tests by body system.
Chest X-Ray

SYNONYM/ACRONYM: Chest radiography, CXR.

AREA OF APPLICATION: Lungs.

CONTRAST: None.

DESCRIPTION: Chest radiography, commonly called chest x-ray, is one of the most frequently performed radiological diagnostic studies. This study yields information about the pulmonary, cardiac, and skeletal systems. The lungs, filled with air, are easily penetrated by x-rays and appear black on chest images. A routine chest x-ray includes a posteroanterior (PA) projection, in which x-rays pass from the posterior to the anterior, and a left lateral projection. Additional projections that may be requested are obliques, lateral decubitus, or lordotic views. Portable x-rays, done in acute or critical situations, can be done at the bedside and usually include only the anteroposterior (AP) projection with additional images taken in a lateral decubitus position if the presence of free pleural fluid or air is in question. Chest images should be taken on full inspiration and erect when possible to minimize heart magnification and demonstrate fluid levels. Expiration images may be added to detect a pneumothorax or locate foreign bodies. Rib detail images may be taken to delineate bone pathology, useful when chest radiographs suggest fractures or metastatic lesions. Fluoroscopic studies of the chest can also be done to evaluate lung and diaphragm movement. In the beginning of the disease process of tuberculosis, asthma, and chronic obstructive pulmonary disease, the results of a chest x-ray may not correlate with the clinical status of the patient and may even be normal.

INDICATIONS:
- Aid in the diagnosis of diaphragmatic hernia, lung tumors, intravenous devices, and metastasis
- Evaluate known or suspected pulmonary disorders, chest trauma, cardiovascular disorders, and skeletal disorders
- Evaluate placement and position of an endotracheal tube, tracheostomy tube, nasogastric feeding tube, pacemaker wires, central venous catheters, Swan-Ganz catheters, chest tubes, and intra-aortic balloon pump
- Evaluate positive PPD or Mantoux tests
- Monitor resolution, progression, or maintenance of disease
- Monitor effectiveness of the treatment regimen

RESULT:

Normal findings in:
- Normal lung fields, cardiac size, mediastinal structures, thoracic spine, ribs, and diaphragm
Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure

Incorrect positioning of the patient, which may produce poor visualization of the area to be examined

Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the examination room with the patient should wear a protective lead apron or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

Abnormal findings in:

- Atelectasis
- Bronchitis
- Curvature of the spinal column (scoliosis)
- Enlarged heart
- Enlarged lymph nodes
- Flattened diaphragm
- Foreign bodies lodged in the pulmonary system
- Fractures of the sternum, ribs, and spine
- Lung pathology, including tumors
- Malposition of tubes or wires
- Mediastinal tumor and pathology
- Pericardial effusion
- Pericarditis
- Pleural effusion
- Pneumonia
- Pneumothorax
- Pulmonary bases, fibrosis, infiltrates
- Tuberculosis
- Vascular abnormalities

Critical values:

- Foreign body
- Malposition of tube, line, or post-op device (pacemaker)
- Pneumonia
- Pneumoperitoneum
- Pneumothorax
- Spine fracture

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

Interfering factors:

This procedure is contraindicated for:

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair the results of the examination:

- Metallic objects within the examination field

Pretest:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses cardiopulmonary status.
- Obtain a history of the patient’s symptoms and complaints, including a list of known allergens.
- Obtain a history of the patient’s cardiovascular and respiratory system, symptoms, and results of
previously performed laboratory tests and diagnostic and surgical procedures.

- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain and explain that no pain will be experienced during the test. Inform the patient that the procedure is performed in the radiology department or at the bedside by a registered radiological technologist, and takes approximately 5 to 15 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove all metallic objects from the area to be examined.
- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**

- Ensure that the patient has removed all external metallic objects from the area to be examined.
- Patients are given a gown, robe, and foot coverings to wear.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the standing position facing the cassette or image detector, with hands on hips, neck extended, and shoulders rolled forward.

- Position the chest with the left side against the image holder for a lateral view.
- For portable examinations, elevate the head of the bed to the high Fowler’s position.
- Ask the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.

**POST-TEST:**

- The report will be sent to the requesting HCP, who will discuss the results with the patient.
- Recognize anxiety related to test results and be supportive of impaired activity related to respiratory capacity and perceived loss of physical activity. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate and determine the need for a change in therapy or progression of the disease process. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include biopsy lung, blood gases, bronchoscopy, CT thoracic, complete blood count, culture mycobacteria, culture sputum, culture viral, electrocardiogram, gram stain, lung perfusion scan, MRI chest, pulmonary function study, pulse oximetry, and TB tests.
- Refer to the Cardiovascular and Respiratory System tables at the back of the book for related tests by body system.
**Chlamydia Group Antibody**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Indirect fluorescent antibody, polymerase chain reaction) Negative or less than fourfold increase in titer.

**DESCRIPTION:** *Chlamydia*, one of the most common sexually transmitted infections, is caused by *Chlamydia trachomatis*. These gram-negative bacteria are called *obligate cell parasites* because they require living cells for growth. There are three serotypes of *C. trachomatis*. One group causes lymphogranuloma venereum, with symptoms of the first phase of the disease appearing 2 to 6 wk after infection; another causes a genital tract infection different from lymphogranuloma venereum, in which symptoms in men appear 7 to 28 days after intercourse (women are generally asymptomatic); and the third causes the ocular disease trachoma (incubation period, 7 to 10 days). *Chlamydia psittaci* is the cause of psittacosis in birds and humans. It is increasing in prevalence as a pathogen responsible for other significant diseases of the respiratory system. The incubation period for *C. psittaci* infections in humans is 7 to 15 days, and is followed by chills, fever, and a persistent nonproductive cough.

*Chlamydia* is difficult to culture and grow, so antibody testing has become the technology of choice. The antigen used in many screening kits is not species specific and can confirm only the presence of *Chlamydia* spp. Newer technology using DNA probes can identify the species. Assays that can specifically identify *C. trachomatis* require special collection and transport kits. They also have specific collection instructions, and the specimens are collected on swabs. The laboratory performing this testing should be consulted before specimen collection.

**INDICATIONS:**
- Establish *Chlamydia* as the cause of atypical pneumonia
- Establish the presence of chlamydial infection

**RESULT:**
**Positive findings in:**
- Chlamydial infection
- Infantile pneumonia *(Related to transmission at birth from an infected mother)*
- Infertility *(Related to scarring of ovaries or fallopian tubes from untreated chlamydia infection)*
- Lymphogranuloma venereum
- Ophthalmia neonatorum *(Related to transmission at birth from an infected mother)*
- Pelvic inflammatory disease
- Urethritis
CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of chlamydia infection.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune and reproductive systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Inform the patient that several tests may be necessary to confirm diagnosis. Any individual positive result should be repeated in 7 to 10 days to monitor a change in titer.
- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize the need to return to have a convalescent blood sample taken in 7 to 14 days. Educate the patient regarding access to counseling services.
- *Social and cultural considerations:* Counsel the patient, as appropriate, as to the risk of sexual transmission and educate the patient regarding proper prophylaxis. Reinforce the importance of strict adherence to the treatment regimen.
- *Social and cultural considerations:* Inform the patient with positive *C. trachomatis* that findings must be reported to a local health department official, who will question the patient regarding his or her sexual partners.
- *Social and cultural considerations:* Offer support, as appropriate, to patients who may be the victim of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nontthreatening atmosphere for a discussion during which you explain the risks of sexually transmitted diseases. It is also important to discuss emotions the patient may...
experience (guilt, depression, anger) as a victim of rape or sexual assault.

- Provide emotional support if the patient is pregnant and if results are positive. Inform the patient that Chlamydia infection during pregnancy places the newborn at risk for pneumonia and conjunctivitis.
- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include culture bacterial (anal, genital), culture viral, gram stain, PAP smear, and syphilis serology.
- Refer to the Immune and Reproductive System tables at the end of the book for related tests by body system.

---

**Chloride, Blood**

**SYNONYM/ACRONYM:** Cl−.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

**REFERENCE VALUE:** (Method: Ion-selective electrode)

**DESCRIPTION:** Chloride is the most abundant anion in the extracellular fluid. Its most important function is in the maintenance of acid-base balance, in which it competes with bicarbonate for sodium. Chloride levels generally increase and decrease proportional to sodium levels and inversely proportional to bicarbonate levels. Chloride also participates with sodium in the maintenance of water balance and aids in the regulation of osmotic pressure. Chloride contributes to gastric acid (hydrochloric acid) for digestion and activation of enzymes. The chloride content of venous blood is slightly higher than that of arterial blood because chloride ions enter red blood cells in response to absorption of carbon dioxide into the cell. As carbon dioxide enters the blood cell, bicarbonate...
leaves and chloride is absorbed in exchange to maintain electrical neutrality within the cell.

Chloride is provided by dietary intake, mostly in the form of sodium chloride. It is absorbed by the gastrointestinal system, filtered out by the glomeruli, and reabsorbed by the renal tubules. Excess chloride is excreted in the urine. Serum values normally remain fairly stable. A slight decrease may be detectable after meals because chloride is used to produce hydrochloric acid as part of the digestive process. Measurement of chloride levels is not as essential as measurement of other electrolytes such as sodium or potassium. Chloride is usually included in standard electrolyte panels to detect the presence of unmeasured anions via calculation of the anion gap. Chloride levels are usually not interpreted apart from sodium, potassium, carbon dioxide, and anion gap.

The patient’s clinical picture needs to be considered in the evaluation of electrolytes. Fluid and electrolyte imbalances are often seen in patients with serious illness or injury because in these cases the clinical situation has affected the normal homeostatic balance of the body. It is also possible that therapeutic treatments being administered are causing or contributing to the electrolyte imbalance. Children and adults are at high risk for fluid and electrolyte imbalances when chloride levels are depleted. Children are considered to be at high risk during chloride imbalance because a positive serum chloride balance is important for expansion of the extracellular fluid compartment.

Anemia, the result of decreased hemoglobin levels, is a frequent issue for elderly patients. Because hemoglobin participates in a major buffer system in the body, depleted hemoglobin levels affect the efficiency of chloride ion exchange for bicarbonate in red blood cells, which in turn affects acid-base balance. Elderly patients are also at high risk because their renal response to change in pH is slower, resulting in a more rapid development of electrolyte imbalance.

**INDICATIONS:**

- Assist in confirming a diagnosis of disorders associated with abnormal chloride values, as seen in acid-base and fluid imbalances
- Differentiate between types of acidosis (hyperchloremic versus anion gap)
- Monitor effectiveness of drug therapy to increase or decrease serum chloride levels

**RESULT:**

**Increased in:**

- Acute renal failure (Decreased renal excretion)
- Cushing’s disease (Related to sodium retention as a result of increased levels of aldosterone; typically chloride levels follow sodium levels)
- Dehydration (Related to hemoconcentration)
- Diabetes insipidus (Hemoconcentration related to excessive urine production)
- Excessive infusion of normal saline (Excessive intake)
- Head trauma with hypothalamic stimulation or damage
- Hyperparathyroidism (primary) (High chloride phosphate ratio is used to assist in diagnosis)
• Metabolic acidosis (Associated with prolonged diarrhea)
• Renal tubular acidosis (Acidosis related to net retention of chloride ions)
• Respiratory alkalosis (e.g., hyperventilation) (Intracellular chloride is replaced by bicarbonate; chloride levels increase)
• Salicylate intoxication (Disturbance in acid base balance resulting in a hyperchloremic acidosis)

Decreased in:
• Addison’s disease (Insufficient aldosterone is produced; potassium is retained while sodium and chloride are lost)
• Burns (Dilutional effect related to sequestration of extracellular fluid)
• Congestive heart failure (Dilutional effect of fluid buildup)
• Diabetic ketoacidosis (Disturbance in acid-base balance with accumulation of ketone bodies and increased chloride)
• Excessive sweating (Excessive loss of chloride without replacement)
• Gastrointestinal loss from vomiting (severe), diarrhea, nasogastric suction, or fistula
• Metabolic alkalosis (Intracellular chloride increases to reduce alkalinity of extracellular fluid)
• Overhydration (Dilutional effect)
• Respiratory acidosis (chronic)
• Salt-losing nephritis (Excessive loss)
• Syndrome of inappropriate antidiuretic hormone secretion (Dilutional effect)
• Water intoxication (Dilutional effect)

CRITICAL VALUES:
Less than 80 mEq/L
Greater than 115 mEq/L

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms. Observe the patient for symptoms of critically decreased or elevated chloride levels. Proper interpretation of chloride values must be made within the context of other electrolyte values and requires clinical knowledge of the patient.

The following may be seen in hypochloremia: twitching or tremors, which may indicate excitability of the nervous system; slow and shallow breathing; and decreased blood pressure as a result of fluid loss. Possible interventions relate to treatment of the underlying cause.

Signs and symptoms associated with hyperchloremia are weakness, lethargy, and deep, rapid breathing. Proper interventions include treatments that correct the underlying cause.

INTERFERING FACTORS:
• Drugs that may cause an increase in chloride levels include acetazolamide, acetylsalicylic acid, ammonium chloride, androgens, bromide, chlorothiazide, cholestyramine, cyclosporine, estrogens, guanethidine, hydrochlorothiazide, lithium, methyldopa, NSAIDs, oxyphenbutazone, phenylbutazone, and triamterene.
• Drugs that may cause a decrease in chloride levels include aldosterone, bicarbonate, corticosteroids, corticotropin, cortisone, diuretics, ethacrynic acid, furosemide, hydroflumethiazide, laxatives (if chronic abuse occurs), mannitol, meralluride, mersalyl, methylthiazide, metolazone, and triamterene.

Many of these drugs can cause a diuretic action that inhibits the tubular reabsorption of chloride. Note: Triamterene has nephrotoxic and azotemic effects, and when
organ damage has occurred, increased serum chloride levels result. Potassium chloride (found in salt substitutes) can lower blood chloride levels and raise urine chloride levels.

- Elevated triglyceride or protein levels may cause a volume-displacement error in the specimen, reflecting falsely decreased chloride values when chloride measurement methods employing predilution specimens are used (e.g., indirect ion-selective electrode, flame photometry).
- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the normal saline contained in the IV solution, falsely increasing the result.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate electrolytes, acid-base balance, and hydration level.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular, endocrine, gastrointestinal, genitourinary, and respiratory systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Specimens should not be collected during hemodialysis.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement. Instruct the patient not to clench and unclench fist immediately before or during specimen collection.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Observe the patient on saline IV fluid replacement therapy for signs of overhydration, especially in cases in which there is a history of cardiac or renal disease. Signs of overhydration include constant, irritable cough; chest rales; dyspnea; or engorgement of neck and hand veins.
- Evaluate the patient for signs and symptoms of dehydration. Check the patient’s skin turgor; mucous membrane moisture, and ability to produce tears. Dehydration is a significant and common finding in geriatric and other patients in whom renal function has deteriorated.

Access additional resources at davisplus.fadavis.com
Monitor daily weights as well as intake and output to determine whether fluid retention is occurring because of sodium and chloride excess. Patients at risk for or with a history of fluid imbalance are also at risk for electrolyte imbalance.

**Nutritional considerations:** Careful observation of the patient on IV fluid replacement therapy is important. A patient receiving a continuous 5% dextrose solution (D5W) may not be taking in an adequate amount of chloride to meet the body’s needs. The patient, if allowed, should be encouraged to drink fluids such as broths, tomato juice, or colas and to eat foods such as meats, seafood, or eggs, which contain sodium and chloride. The use of table salt may also be appropriate.

**Nutritional considerations:** Instruct patients with elevated chloride levels to avoid eating or drinking anything containing sodium chloride salt. The patient or caregiver should also be encouraged to read food labels to determine which products are suitable for a low-sodium diet.

**Nutritional considerations:** Instruct patients with low chloride levels that a decrease in iron absorption may occur as a result of less chloride available to form gastric acid, which is essential for iron absorption. In prolonged periods of chloride deficit, iron-deficiency anemia could develop.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ACTH, anion gap, blood gases, carbon dioxide, complete blood count hematocrit, complete blood count hemoglobin, osmolality, potassium, protein total and fractions, and sodium.
- Refer to the Cardiovascular, Endocrine, Gastrointestinal, Genitourinary, and Respiratory System tables at the end of the book for related test by body system.

---

**Chloride, Sweat**

**SYNONYM/ACRONYM:** Sweat test, pilocarpine iontophoresis sweat test, sweat chloride.

**SPECIMEN:** Sweat (0.1 mL minimum) collected by pilocarpine iontophoresis.

**REFERENCE VALUE:** (Method: Ion-specific electrode or titration)

<table>

The result must be interpreted with regard to the patient’s age and clinical presentation. The patient must be at least 48 hr old.
DESCRIPTION: Cystic fibrosis (CF) is a genetic disease that affects normal functioning of the exocrine glands, causing them to excrete large amounts of electrolytes. Patients with CF have sweat electrolyte levels two to five times normal. Sweat test values, with family history and signs and symptoms, are required to establish a diagnosis of CF. CF is transmitted as an autosomal recessive trait and is characterized by abnormal exocrine secretions within the lungs, pancreas, small intestine, bile ducts, and skin. Clinical presentation may include chronic problems of the gastrointestinal and/or respiratory system. Sweat conductivity is a screening method that estimates chloride levels. Sweat conductivity values greater than or equal to 50 mEq/L should be referred for quantitative analysis of sweat chloride. Testing of stool samples for decreased trypsin activity has been used as a screen for CF in infants and children, but this is a much less reliable method than the sweat test. In-vitro diagnostic (IVD) medical devices are available for noninvasive saliva DNA self-collection kits. Genetic testing can be reliably performed on the harvested DNA material to screen for genetic mutations associated with CF and can assist in confirming a diagnosis of CF, but the sweat electrolyte test is still considered the gold standard diagnostic for CF.

The sweat test is a noninvasive study done to assist in the diagnosis of CF when considered with other test results and physical assessments. This test is usually performed on children, although adults may also be tested; it is not usually ordered on adults because results can be highly variable and should be interpreted with caution. Sweat for specimen collection is induced by a small electrical current carrying the drug pilocarpine. The test measures the concentration of chloride produced by the sweat glands of the skin. A high concentration of chloride in the specimen indicates the presence of CF. The sweat test is used less commonly to measure the concentration of sodium ions for the same purpose.

INDICATIONS:
- Assist in the diagnosis of CF
- Screen for CF in individuals with a family history of the disease
- Screen for suspected CF in children with recurring respiratory infections
- Screen for suspected CF in infants with failure to thrive and infants who pass meconium late
- Screen for suspected CF in individuals with malabsorption syndrome

RESULT:
Increased in:
- Conditions that affect electrolyte distribution and excretion may produce false positive sweat test results.
- Addison’s disease
- Alcoholic pancreatitis (Dysfunction of CF gene linked to pancreatic disease susceptibility)
- CF
- Chronic pulmonary infections (Related to undiagnosed CF)
- Congenital adrenal hyperplasia
- Diabetes insipidus
- Familial cholestasis
- Familial hypoparathyroidism
- Fucosidosis
• Glucose-6-phosphate dehydrogenase deficiency
• Hypothyroidism
• Mucopolysaccharidosis
• Nephrogenic diabetes insipidus
• Renal failure

**Decreased in:**
Conditions that affect electrolyte distribution and retention may produce false negative sweat test results.
• Edema
• Hypoaldosteronism
• Hypoproteinemia
• Sodium depletion

**CRITICAL VALUES:**

- **20 yr or younger:** Greater than 60 mmol/L considered diagnostic of CF
- **Older than 20 years:** Greater than 70 mmol/L considered diagnostic of CF

Note and immediately report to the health care provider (HCP) any critically increased values and related symptoms. Values should be interpreted with consideration of family history and clinical signs and symptoms.

The validity of the test result is affected tremendously by proper specimen collection and handling. Before proceeding with appropriate patient education and counseling, it is important to perform duplicate testing on patients whose results are in the diagnostic or intermediate ranges. A negative test should be repeated if test results do not support the clinical picture.

**INTERFERING FACTORS:**

• An inadequate amount of sweat may produce inaccurate results.
• This test should not be performed on patients with skin disorders (e.g., rash, erythema, eczema).
• Improper cleaning of the skin or improper application of gauze pad or filter paper for collection affects test results.
• Hot environmental temperatures may reduce the sodium chloride concentration in sweat; cool environmental temperatures may reduce the amount of sweat collected.
• If the specimen container that stores the gauze or filter paper is handled without gloves, the test results may show a false increase in the final weight of the collection container.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of cystic fibrosis.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine and respiratory systems, especially failure to thrive or CF in other family members, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient and caregiver. Encourage the caregiver to stay with and support the child during the test. The iontophoresis and specimen collection usually takes approximately 75 to 90 min. Address concerns about pain and explain that there is no pain associated with the test, but a stinging sensation may be experienced when the low electrical current is applied at the site.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**

- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.
- The patient is placed in a position that will allow exposure of the site on the forearm or thigh. To ensure collection of an adequate amount of sweat in a small infant, two sites (right forearm and right thigh) can be used. The patient should be covered to prevent cool environmental temperatures from affecting sweat production. The site selected for iontophoresis should never be the chest or left side because of the risk of cardiac arrest from the electrical current.
- The site is washed with distilled water and dried. A positive electrode is attached to the site on the right forearm or right thigh and covered with a pad that is saturated with pilocarpine, a drug that stimulates sweating. A negative electrode is covered with a pad that is saturated with bicarbonate solution. Iontophoresis is achieved by supplying a low (4 to 5 mA) electrical current via the electrode for 12 to 15 min. Battery-powered equipment is preferred over an electrical outlet to supply the current.
- The electrodes are removed, revealing a red area at the site, and the site is washed with distilled water and dried to remove any possible contaminants on the skin.
- Prewighted disks made of filter paper are placed on the site with a forceps; to prevent evaporation of sweat collected at the site, the disks are covered with paraffin or plastic and sealed at the edges. The disks are left in place for about 1 hr. Distract the child with books or games to allay fears.
- After 1 hr, the paraffin covering is removed, and disks are placed in a prewighted container with a forceps. The container is sealed and sent immediately to the laboratory for weighing and analysis of chloride content. At least 100 mg of sweat is required for accurate results.
- Terminate the test if the patient complains of burning at the electrode site. Reposition the electrode before the test is resumed.
- Promptly transport the specimen to the laboratory for processing and analysis. Do not directly handle the prewighted specimen container or filter paper.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient/caregiver.
- Observe the site for unusual color, sensation, or discomfort.
- Inform the patient and caregiver that redness at the site fades in 2 to 3 hr.
- Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.
- **Nutritional considerations:** If appropriate, instruct the patient and caregiver that nutrition may be altered because of impaired digestive processes associated with CF. Increased viscosity of exocrine gland secretion may lead to poor absorption of digestive enzymes and fat-soluble vitamins, necessitating oral intake of digestive enzymes with each meal, and calcium and vitamin (A, D, E, and K) supplementation. Malnutrition also is seen commonly in patients with chronic, severe respiratory disease for many reasons, including fatigue, lack of appetite, and gastrointestinal distress. Research has estimated that the daily caloric intake needed for children with CF between 4 and 7 yr may be 2000 to 2800 and for teens 3000 to 5000. Tube feeding may be necessary to supplement regular high-calorie meals. To prevent pulmonary infection and decrease the extent of lung tissue damage, adequate intake of vitamins A and C is also important. Excessive loss of sodium chloride through the sweat glands of a patient with CF may necessitate increased salt intake, especially in environments where increased sweating is induced. The importance of following the prescribed diet should be stressed to the patient and caregiver.
If appropriate, instruct the patient and caregiver that ineffective airway clearance related to excessive production of mucus and decreased ciliary action may result. Chest physical therapy and the use of aerosolized antibiotics and mucus thinning drugs are an important part of the daily treatment regimen.

Recognize anxiety related to test results, and be supportive of impaired activity related to perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Help the patient and caregiver to cope with long-term implications. Recognize that anticipatory anxiety and grief related to potential lifestyle changes may be expressed when someone is faced with a chronic disorder. Provide information regarding genetic counseling and possible screening of other family members if appropriate. Provide contact information, if desired, for the Cystic Fibrosis Foundation (www.cff.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Explain that a positive sweat test alone is not diagnostic of CF; repetition of borderline and positive tests is generally recommended. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include α₁-antitrypsin/phenotype, amylase, anion gap, biopsy chorionic villus, blood gases, fecal analysis, fecal fat, osmolality, phosphorus, potassium, and sodium.
- Refer to the Endocrine and Respiratory System tables at the end of the book for related tests by body system.

**Cholangiography, Percutaneous Transhepatic**

**SYNONYM/ACRONYM:** Percutaneous cholecystogram, PTC, PTHC.

**AREA OF APPLICATION:** Biliary system.

**CONTRAST:** Radiopaque iodine-based contrast medium.

**DESCRIPTION:** Percutaneous transhepatic cholangiography (PTC) is a test used to visualize the biliary system in order to evaluate persistent upper abdominal pain after cholecystectomy and to determine the presence and cause of obstructive jaundice.

The liver is punctured with a thin needle under fluoroscopic guidance, and contrast medium is slowly injected as the needle is withdrawn. This test visualizes the biliary ducts without depending on the gallbladder’s concentrating ability.
The intrahepatic and extrahepatic biliary ducts, and occasionally the gallbladder, can be visualized to determine possible obstruction. In obstruction of the extrahepatic ducts, a catheter can be placed in the duct to allow external drainage of bile. Endoscopic retrograde cholangiopancreatography (ERCP) and PTC are the only methods available to view the biliary tree in the presence of jaundice. ERCP poses less risk and is probably done more often. PTC is an invasive procedure and has potential risks, including bleeding, septicemia, bile peritonitis, and extravasation of the contrast medium.

**INDICATIONS:**
- Aid in the diagnosis of obstruction caused by gallstones, benign strictures, malignant tumors, congenital cysts, and anatomic variations
- Determine the cause, extent, and location of mechanical obstruction
- Determine the cause of upper abdominal pain after cholecystectomy
- Distinguish between obstructive and nonobstructive jaundice

**RESULT:**

**Normal findings in:**
- Biliary ducts are normal in diameter, with no evidence of dilation, filling defects, duct narrowing, or extravasation.
- Contrast medium fills the ducts and flows freely.
- Gallbladder appears normal in size and shape.

**Abnormal findings in:**
- Anatomic biliary or pancreatic duct variations
- Biliary sclerosis
- Cholangiocarcinoma
- Cirrhosis
- Common bile duct cysts
- Gallbladder carcinoma
- Gallstones
- Hepatitis
- Nonobstructive jaundice
- Pancreatitis
- Sclerosing cholangitis
- Tumors, strictures, inflammation, or gallstones of the common bile duct

**CRITICAL VALUES:** N/A

*This procedure is contraindicated for:*
- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Patients with cholangitis. The injection of the contrast medium can increase biliary pressure, leading to bacteremia, septicemia, and shock.
- Patients with postoperative wound sepsis, hypersensitivity to iodine, or acute renal failure.
- Patients with bleeding disorders, massive ascites, or acute renal failure.

**Factors that may impair clear imaging:**
- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects within the examination field which may inhibit organ visualization and cause unclear images
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
• The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
• Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
• Peritonitis may occur as a result of bile extravasation.
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the examination room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

Ensure that this procedure is performed before an upper GI study or barium swallow.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note time and date of last dose.

If contrast medium is scheduled to be used, patients receiving metformin (glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.

Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in the radiology department by a HCP, with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, or sedatives.

Type and screen the patient’s blood for possible transfusion.

Inform the patient that a laxative and cleansing enema may be needed the day before the procedure, with cleansing enemas on the morning of the procedure depending on the institution’s policy.

Instruct the patient to remove all external metallic objects from the area to be examined.

The patient should fast and restrict fluids for 8 hr prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the biliary ducts.
- Obtain a history of the patient’s complaints, including a list of known allergies, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, and dyes.
- Obtain a history of the patient’s GI and hepatobiliary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

NURSING IMPLICATIONS AND PROCEDURE
CHOLANGIOGRAPHY, PERCUTANEOUS TRANSHEPATIC

At the end of the procedure, the contrast medium is aspirated from the biliary ducts, relieving pressure on the dilated ducts.

If an obstruction is found during the procedure, a catheter is inserted into the bile duct to allow drainage of bile.

Maintain pressure over the needle insertion site for several hours if bleeding is persistent.

Observe the needle site for bleeding, inflammation, or hematoma formation.

Establish a closed and sterile drainage system if a catheter is left in place.

Post-Test:

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated.

Protocols may vary from facility to facility.

Monitor for reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Renal function should be assessed before metformin is restarted.

Observe the puncture site for signs of bleeding, hematoma formation, ecchymosis, or leakage of bile. Notify the HCP if any of these is present.

Advise the patient to watch for symptoms of infection, such as pain, fever, increased pulse rate, and muscle aches.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed.

IntraTest:

Ensure that the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.

Ensure the patient has removed all external metallic objects from the area to be examined.

Assess for completion of bowel preparation according to the institution’s procedure.

If the patient has a history of allergic reactions to any relevant substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

Observe standard precautions, and follow the general guidelines in Appendix A.

Place the patient in the supine position on an exam table.

A kidney, ureter, and bladder (KUB) or plain film is taken to ensure that no barium or stool will obscure visualization of the biliary system.

An area over the abdominal wall is anesthetized, and the needle is inserted and advanced under fluoroscopic guidance. Contrast medium is injected when placement is confirmed by the free flow of bile.

A specimen of bile may be sent to the laboratory for culture and cytological analysis.

At the end of the procedure, the contrast medium is aspirated from the biliary ducts, relieving pressure on the dilated ducts.

If an obstruction is found during the procedure, a catheter is inserted into the bile duct to allow drainage of bile.

Maintain pressure over the needle insertion site for several hours if bleeding is persistent.

Observe the needle site for bleeding, inflammation, or hematoma formation.

Establish a closed and sterile drainage system if a catheter is left in place.

Post-Test:

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated.

Protocols may vary from facility to facility.

Monitor for reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Renal function should be assessed before metformin is restarted.

Observe the puncture site for signs of bleeding, hematoma formation, ecchymosis, or leakage of bile. Notify the HCP if any of these is present.

Advise the patient to watch for symptoms of infection, such as pain, fever, increased pulse rate, and muscle aches.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed.

IntraTest:

Ensure that the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.

Ensure the patient has removed all external metallic objects from the area to be examined.

Assess for completion of bowel preparation according to the institution’s procedure.

If the patient has a history of allergic reactions to any relevant substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

Observe standard precautions, and follow the general guidelines in Appendix A.

Place the patient in the supine position on an exam table.

A kidney, ureter, and bladder (KUB) or plain film is taken to ensure that no barium or stool will obscure visualization of the biliary system.

An area over the abdominal wall is anesthetized, and the needle is inserted and advanced under fluoroscopic guidance. Contrast medium is injected when placement is confirmed by the free flow of bile.

A specimen of bile may be sent to the laboratory for culture and cytological analysis.
Cholangiography, Postoperative

**SYNONYM/ACRONYM:** T-tube cholangiography.

**AREA OF APPLICATION:** Gallbladder, bile ducts.

**CONTRAST:** Iodinated contrast medium.

**DESCRIPTION:** After cholecystectomy, a self-retaining, T-shaped tube may be inserted into the common bile duct. Postoperative (T-tube) cholangiography is a fluoroscopic and radiographic examination of the biliary tract that involves the injection of a contrast medium through the T-tube inserted during surgery. This test may be performed at the time of surgery and again 7 to 10 days after cholecystectomy to assess the patency of the common bile duct and to detect any remaining calculi. T-tube placement may also be done after a liver transplant because biliary duct obstruction or anastomotic leakage is possible. This test should be performed before any gastrointestinal (GI) studies using barium and after any studies involving the measurement of iodinated compounds.

**INDICATIONS:**
- Determine biliary duct patency before T-tube removal
- Identify the cause, extent, and location of obstruction after surgery

**RESULT:**

*Normal findings in:*
- Biliary ducts are normal in size.
- Contrast medium fills the ductal system and flows freely.

*Abnormal findings in:*
- Appearance of channels of contrast medium outside of the biliary ducts, indicating a fistula
- Filling defects, dilation, or shadows within the biliary ducts, indicating calculi or neoplasm

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

*This procedure is contraindicated for:*
- Patients with allergies to shellfish or iodinated dye.

**RELATED MONOGRAPHS:**
- Related tests include ALT, amylase, AMA, AST, biopsy liver, cancer antigens, cholangiography postoperative, cholangiopancreatography endoscopic retrograde, CT abdomen, GGT, hepatitis antigens and antibodies (A, B, C), hepatobiliary scan, KUB studies, laparoscopy abdominal, lipase, MRI abdomen, peritoneal fluid analysis, pleural fluid analysis, and US liver and biliary tract.
- Refer to the Gastrointestinal and Hepatobiliary System tables in the back of the book for related tests by body system.
The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Patients with cholangitis. The injection of the contrast medium can increase biliary pressure, leading to bacteremia, septicemia, and shock.
- Patients with postoperative wound sepsis, hypersensitivity to iodine, or acute renal failure.

**Factors that may impair clear imaging:**
- Gas or feces in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

**Other considerations:**
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Air bubbles resembling calculi may be seen if there is inadvertent injection of air.
- Peritonitis may occur as a result of bile extravasation.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the examination room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their radiation level.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the biliary ducts.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics and dyes.
- Obtain a history of results of the patient’s GI and hepatobiliary system, symptoms, and previously performed laboratory tests and diagnostic and surgical procedures.
- Ensure that this procedure is performed before an upper GI study or barium swallow.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix F).
- If contrast medium is scheduled to be used, patients receiving metformin (glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.
- Review the procedure with the patient. Address concerns about pain and explain that there may be moments of
discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in the radiology department by a HCP and takes approximately 30 to 60 minutes.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient to remove jewelry and other metallic objects in the area to be examined.

Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure that the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any relevant substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
- Clamp the T-tube 24 hr before and during the procedure, if ordered, to help prevent air bubbles from entering the ducts.
- An x-ray of the abdomen is obtained to determine if any residual contrast medium is present from previous studies.

The patient is placed on an examination table in the supine position.

The area around the T-tube is draped; the end of the T-tube is cleansed with 70% alcohol. If the T-tube site is inflamed and painful, a local anesthetic (e.g., lidocaine) may be injected around the site. A needle is inserted into the open end of the T-tube, and the clamp is removed.

Contrast medium is injected, and fluoroscopy is performed to visualize contrast medium moving through the duct system.

The patient may feel a bloating sensation in the upper right quadrant as the contrast medium is injected. The tube is clamped, and images are taken. A delayed image may be taken 15 min later to visualize passage of the contrast medium into the duodenum.

For procedures done after surgery, the T-tube is removed if findings are normal; a dry, sterile dressing is applied to the site.

If retained calculi are identified, the T-tube is left in place for 4 to 6 wk until the tract surrounding the T-tube is healed to perform a percutaneous removal.

**POST-TEST:**

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

Monitor T-tube site and change sterile dressing, as ordered.

Instruct the patient on the care of the site and dressing changes.

Monitor for reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
CHOLANGIOPANCREATEOGRAPHY, ENDOSCOPIC RETROGRADE

- Carefully monitor the patient for fatigue and fluid and electrolyte imbalance.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include CT abdomen, hepatobiliary scan, KUB, MRI abdomen, and US liver and biliary system.
- Refer to the Gastrointestinal and Hepatobiliary System tables in the back of the book for tests by related body systems.

SYNONYM/ACRONYM: ERCP.

AREA OF APPLICATION: Gallbladder, bile ducts, pancreatic ducts.

CONTRAST: Iodinated contrast medium.

DESCRIPTION: Endoscopic retrograde cholangiopancreatography (ERCP) allows direct visualization of the pancreatic and biliary ducts with a flexible endoscope and, after injection of contrast material, with x-rays. It allows the physician to view the pancreatic, hepatic, and common bile ducts and the ampulla of Vater. ERCP and percutaneous transhepatic cholangiography (PTC) are the only procedures that allow direct visualization of the biliary and pancreatic ducts. ERCP is less invasive and has less morbidity than PTC. It is useful in the evaluation of patients with jaundice, because the ducts can be visualized even when the patient’s bilirubin level is high. (In contrast, oral cholecystography and IV cholangiography are not able to visualize the biliary system when the patient has high bilirubin levels.) By endoscopy, the distal end of the common bile duct can be widened, and gallstones can be removed and stents placed in narrowed bile ducts to allow bile to be drained in jaundiced patients. During endoscopy, specimens of suspicious tissue can be taken for pathological review, and manometry pressure readings can be obtained from the bile and pancreatic ducts. ERCP is used in the diagnosis and follow-up of pancreatic disease.

Access additional resources at davisplus.fadavis.com
INDICATIONS:
- Assess jaundice of unknown cause to differentiate biliary tract obstruction from liver disease
- Collect specimens for cytology
- Identify obstruction caused by calculi, cysts, ducts, strictures, stenosis, and anatomic abnormalities
- Retrieve calculi from the distal common bile duct and release strictures
- Perform therapeutic procedures, such as sphincterotomy and placement of biliary drains

RESULT:

Normal findings in:
- Normal appearance of the duodenal papilla
- Patency of the pancreatic and common bile ducts

Abnormal findings in:
- Duodenal papilla tumors
- Pancreatic cancer
- Pancreatic fibrosis
- Pancreatitis
- Sclerosing cholangitis

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.

Factors that may impair clear imaging:
- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Previous surgery involving the stomach or duodenum, which can make locating the duodenal papilla difficult
- A patient with Zenker’s diverticulum involving the esophagus, who may be unable to undergo ERCP
- A patient with unstable cardiopulmonary status, blood coagulation defects, or cholangitis (test may have to be rescheduled unless the patient received antibiotic therapy before the test)
- A patient with known acute pancreatitis
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the examination room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the biliary ducts.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, and dyes.
- Obtain a history of the patient’s GI and hepatobiliary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Ensure that this procedure is performed before an upper GI study or barium swallow.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.
- If contrast medium is scheduled to be used, patients receiving metformin (glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.
- Review the procedure with the patient. Address concerns about pain and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a GI lab or radiology department, usually by a HCP, with support staff, and takes approximately 30 to 60 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, or sedatives.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- The patient should fast and restrict fluids for 8 hr prior to the procedure.
- Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:
- Ensure the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.
- Ensure the patient has removed all external metallic objects from the area to be examined.
- Assess for completion of bowel preparation according to the institution’s procedure.
- If the patient has a history of allergic reactions to any relevant substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate containers with the corresponding patient demographics, date, and time of collection if cytology samples are collected.
- Insert an IV line for administration of drugs, as needed.
- Administer ordered sedation.
An x-ray of the abdomen is obtained to determine if any residual contrast medium is present from previous studies.

The oropharynx is sprayed or swabbed with a topical local anesthetic.

The patient is placed on an examination table in the left lateral position with the left arm behind the back and right hand at the side with the neck slightly flexed. A protective guard is inserted into the mouth to cover the teeth. A bite block can also be inserted to maintain adequate opening of the mouth.

The endoscope is passed through the mouth with a dental suction device in place to drain secretions. A side-viewing flexible fiberoptic endoscope is passed into the duodenum, and a small cannula is inserted into the duodenal papilla (ampulla of Vater).

The patient is placed in the prone position. The duodenal papilla is visualized and cannulated with a catheter. Occasionally the patient can be turned slightly to the right side to aid in visualization of the papilla.

IV glucagon or anticholinergics can be administered to minimize duodenal spasm and to facilitate visualization of the ampulla of Vater.

ERCP manometry can be done at this time to measure the pressure in the bile duct, pancreatic duct, and sphincter of Oddi at the papilla area via the catheter as it is placed in the area before the contrast medium is injected.

When the catheter is in place, contrast medium is injected into the pancreatic and biliary ducts via the catheter, and fluoroscopic images are taken. Biopsy specimens for cytological analysis may be obtained.

Place specimens in appropriate containers, label them properly, and promptly transport them to the laboratory.

**POST-TEST:**

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Do not allow the patient to eat or drink until the gag reflex returns, after which the patient is permitted to eat lightly for 12 to 24 hr.

Instruct the patient to resume usual diet, fluids, medications, and activity after 24 hr, or as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

Monitor for reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Tell the patient to expect some throat soreness and possible hoarseness. Advise the patient to use warm gargles, lozenges, ice packs to the neck, or cool fluids to alleviate throat discomfort.

Inform the patient that any belching, bloating, or flatulence is the result of air insufflation.

Emphasize that any severe pain, fever, difficulty breathing, or expectoration of blood must be reported to the HCP immediately.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.

Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include amylase, CT abdomen, hepatobiliary scan, KUB studies, lipase, MRI abdomen, peritoneal fluid analysis, pleural fluid analysis, and US liver and biliary system.

Refer to the Gastrointestinal and Hepatobiliary System tables in the back of the book for related tests by body system.
**Cholesterol, HDL and LDL**

**DESCRIPTION:** High-density lipoprotein cholesterol (HDLC) and low-density lipoprotein cholesterol (LDLC) are the major transport proteins for cholesterol in the body. It is believed that HDLC may have protective properties in that its role includes transporting cholesterol from the arteries to the liver. LDLC is the major transport protein for cholesterol to the arteries from the liver. LDLC can be

---

Access additional resources at davisplus.fadavis.com
calculated using total cholesterol, total triglycerides, and HDLC levels. Beyond the total cholesterol, HDL and LDL cholesterol values, other important risk factors must be considered. The Framingham algorithm can assist in estimating the risk of developing coronary artery disease (CAD) within a 10-yr period. The National Cholesterol Education Program (NCEP) also provides important guidelines. The latest NCEP guidelines for target lipid levels, major risk factors, and therapeutic interventions are outlined in Adult Treatment Panel III (ATP III) (nhlbi.nih.gov/guidelines/cholesterol/index.htm).

Studies have shown that CAD is inversely related to LDLC particle number and size. The NMR lipid profile uses NMR imaging spectroscopy to determine LDLC particle number and size in addition to measurement of the traditional lipid markers.

HDL levels less than 40 mg/dL in men and women represent a coronary risk factor. There is an inverse relationship between HDLC and risk of CAD (i.e., lower HDLC levels represent a higher risk of CAD). Levels of LDL in terms of risk for CAD are directly proportional to risk and vary by age group. The LDLC can be estimated using the Friedewald formula:

\[
LDLC = \frac{(Total\ Cholesterol) - (HDL) - (VLDLC)}{1}
\]

Very-low-density lipoprotein cholesterol (VLDLC) is estimated by dividing the triglycerides (conventional units) by 5. Triglycerides in SI units would be divided by 2.18 to estimate VLDLC. It is important to note that the formula is valid only if the triglycerides are less than 400 mg/dL or 4.52 mmol/L.

**INDICATIONS:**
- Determine the risk of cardiovascular disease
- Evaluate the response to dietary and drug therapy for hypercholesterolemia
- Investigate hypercholesterolemia in light of family history of cardiovascular disease

**RESULT:**
Although the exact pathophysiology is unknown, cholesterol is required for many functions at the cellular and organ level. Elevations of cholesterol are associated with conditions caused by an inherited defect in lipoprotein metabolism, liver disease, kidney disease, or a disorder of the endocrine system. Decreases in cholesterol levels are associated with conditions caused by malnutrition, malabsorption, liver disease, and sudden increased utilization.

- **HDL increased in:**
  - Alcoholism
  - Biliary cirrhosis
  - Chronic hepatitis
  - Exercise
  - Familial hyper-α-lipoproteinemia

- **HDL decreased in:**
  - Abetalipoproteinemia
  - Cholestasis
  - Chronic renal failure
  - Fish-eye disease
  - Genetic predisposition or enzyme/cofactor deficiency
  - Hepatocellular disorders
  - Hypertriglyceridemia
  - Nephrotic syndrome
  - Obesity
  - Premature CAD
  - Sedentary lifestyle
  - Smoking
  - Tangier disease
  - Syndrome X (metabolic syndrome)
  - Uncontrolled diabetes
**LDLC increased in:**
- Anorexia nervosa
- Chronic renal failure
- Corneal arcus
- Cushing’s syndrome
- Diabetes
- Diet high in cholesterol and saturated fat
- Dysglobulinemias
- Hepatic disease
- Hepatic obstruction
- Hyperlipoproteinemia types IIA and IIB
- Hypothyroidism
- Nephrotic syndrome
- Porphyria
- Pregnancy
- Premature CAD
- Syndrome X (metabolic syndrome)
- Tendon and tuberous xanthomas

**LDLC decreased in:**
- Acute stress (severe burns, illness)
- Chronic anemias
- Chronic pulmonary disease
- Genetic predisposition or enzyme/cofactor deficiency
- Hyperthyroidism
- Hypolipoproteinemia and abetalipoproteinemia
- Inflammatory joint disease
- Myeloma
- Reye’s syndrome
- Severe hepatocellular destruction or disease
- Tangier disease

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase HDLC levels include albuterol, anticonvulsants, cholestyramine, cimetidine, clofibrate and other fibric acid derivatives, estrogens, ethanol (moderate use), lovastatin, niacin, oral contraceptives, pindolol, pravastatin, prazosin, and simvastatin.
- Drugs that may decrease HDLC levels include acetobutol, atenolol, danazol, diuretics, etretinate, interferon, isotretinoin, linseed oil, metoprolol, neomycin, nonselective β-adrenergic blocking agents, probucol, progesterone, steroids, and thiazides.
- Drugs that may increase LDLC levels include androgens, catecholamines, chenodiol, cyclosporine, danazol, diuretics, etretinate, glucogenic corticosteroids, and progestins.
- Drugs that may decrease LDLC levels include aminosalicylic acid, cholestyramine, colestatipol, estrogens, fibric acid derivatives, interferon, lovastatin, neomycin, niacin, pravastatin, prazosin, probucol, simvastatin, terazosin, and thyroxine.
- Some of the drugs used to lower total cholesterol and LDLC or increase HDLC may cause liver damage.
- Grossly elevated triglyceride levels invalidate the Friedewald formula for mathematical estimation of LDLC; if the triglyceride level is greater than 400 mg/dL, the formula should not be used.
- Fasting before specimen collection is highly recommended. Ideally, the patient should be on a stable diet for 3 wk and fast for 12 hr before specimen collection.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess and monitor risk for coronary artery disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
Obtain a history of the patient’s cardiovascular system and results of previously performed laboratory tests and diagnostic and surgical procedures. The presence of other risk factors, such as family history of heart disease, smoking, obesity, diet, lack of physical activity, hypertension, diabetes, previous myocardial infarction, and previous vascular disease, should be investigated.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient to fast for 12 hr before specimen collection. Protocols may vary from facility to facility.

Confirm with the requesting health care provider (HCP) that the patient should withhold medications known to influence test results, and instruct the patient accordingly.

There are no fluid restrictions unless by medical direction.

**INTRATEST:**

Ensure that the patient has complied with dietary and medication restrictions as well as other pretesting preparations; assure that food has been restricted for at least 12 hr prior to the procedure.

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A report of the results will be sent to the requesting HCP who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, and medications, as directed by the HCP.

**Nutritional considerations:** Decreased HDLC level and increased LDLC level may be associated with CAD. Nutritional therapy is recommended for the patient identified to be at high risk for developing CAD. If overweight, the patient should be encouraged to achieve a normal weight. The American Heart Association Step 1 and Step 2 diets may be helpful in achieving a goal of lowering total cholesterol and triglyceride levels. The Step 1 diet emphasizes a reduction in foods high in saturated fats and cholesterol. Red meats, eggs, and dairy products are the major sources of saturated fats and cholesterol. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol and simple carbohydrates from the diet. The Step 2 diet recommends stricter reductions.

**Social and cultural considerations:** Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight-control education.

Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association.
Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, ANP, blood gases, BNP, calcium (total and ionized), cholesterol total, CT cardiac scoring, CRP, CK and isoenzymes, echocardiography, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI chest, MI scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, triglycerides, and troponin. Refer to the Cardiovascular System table at the back of the book for related tests by body system.

**Cholesterol, Total**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable. It is important to use the same tube type when serial specimen collections are anticipated for consistency in testing.

**REFERENCE VALUE:** (Method: Spectrophotometry)

Plasma values may be 10% lower than serum values.
DESCRIPTION: Cholesterol is a lipid needed to form cell membranes and a component of the materials that render the skin waterproof. It also helps form bile salts, adrenal corticosteroids, estrogen, and androgens. Cholesterol is obtained from the diet (exogenous cholesterol) and also synthesized in the body (endogenous cholesterol). Although most body cells can form some cholesterol, it is produced mainly by the liver and intestinal mucosa. Cholesterol is an integral component in cell membrane maintenance and hormone production. Very low cholesterol values, as are sometimes seen in critically ill patients, can be as life-threatening as very high levels.

According to the National Cholesterol Education Program, maintaining cholesterol levels less than 200 mg/dL significantly reduces the risk of coronary heart disease; no age and gender stratification is presented as part of its recommendation. Numerous studies have been done, and there are inconsistencies among the studies as to target “normals” segregated by age and gender. Beyond the total cholesterol and high-density lipoprotein cholesterol (HDLC) values, other important risk factors must be considered. The Framingham algorithm can assist in estimating the risk of developing coronary artery disease (CAD) within a 10-yr period. Many myocardial infarctions occur even in patients whose cholesterol levels are considered to be within acceptable limits or who are in a moderate-risk category. The combination of risk factors and lipid values helps identify individuals at risk so that appropriate interventions can be taken. If the cholesterol level is greater than 200 mg/dL, repeat testing after a 12- to 24-hr fast is recommended.

INDICATIONS:
- Assist in determining risk of cardiovascular disease
- Assist in the diagnosis of nephrotic syndrome, hepatic disease, pancreatitis, and thyroid disorders
- Evaluate the response to dietary and drug therapy for hypercholesterolemia
- Investigate hypercholesterolemia in light of family history of cardiovascular disease

RESULT:
Increased in:
Although the exact pathophysiology is unknown, cholesterol is required for many functions at the cellular and organ level. Elevations of cholesterol are associated with conditions caused by an inherited defect in lipoprotein metabolism, liver disease, kidney disease, or a disorder of the endocrine system.
- Acute intermittent porphyria
- Alcoholism
- Anorexia nervosa
- Cholestasis
- Chronic renal failure
- Diabetes (with poor control)
- Diets high in cholesterol and fats
- Familial hyperlipoproteinemia
- Glomerulonephritis
- Glycogen storage disease (von Gierke disease)
- Gout
- Hypothyroidism (primary)
- Ischemic heart disease
- Nephrotic syndrome
- Obesity
- Pancreatic and prostatic malignancy
- Pregnancy
• Syndrome X (metabolic syndrome)
• Werner’s syndrome

**Decreased in:**
Although the exact pathophysiology is unknown, cholesterol is required for many functions at the cellular and organ level. Decreases in cholesterol levels are associated with conditions caused by malnutrition, malabsorption, liver disease, and sudden increased utilization.

• Burns
• Chronic myelocytic leukemia
• Chronic obstructive pulmonary disease
• Hyperthyroidism
• Liver disease (severe)
• Malabsorption and malnutrition syndromes
• Myeloma
• Pernicious anemia
• Polycythemia vera
• Severe illness
• Sideroblastic anemias
• Tangier disease
• Thalassemia
• Waldenström’s macroglobulinemia

**CRITICAL VALUES:** N/A.

**INTERFERING FACTORS:**
- Drugs that may increase cholesterol levels include amiodarone, androgens, catecholamines, cyclosporine, danazol, diclofenac, disulfiram, glucogenic corticosteroids, ibuprofen, isotretinoin, levodopa, methyclothiazide, miconazole (owing to castor oil vehicle, not the drug), nafarelin, nandrolone, some oral contraceptives, oxymetholone, phenobarbital, phenothiazine, prochlorperazine, and sotalol.
- Drugs that may decrease cholesterol levels include acebutolol, amiloride, aminosalicylic acid, ascorbic acid, asparaginase, atenolol, atorvastatin, beclorate, bezafibrate, carbutamide, cerivastatin, cholestyramine, ciprofibrate, clofibrate, clonidine, colesteplol, dextrothyroxine, doxazosin, enalapril, estrogens, fenfluramine, fenofibrate, fluvastatin, gemfibrozil, haloperidol, hydralazine, interferon, lovastatin, neomycin, niacin, pravastatin, probucol, simvastatin, tamoxifen, terazosin, thyroxine, ursodiol, and verapamil.

- Ingestion of alcohol 12 to 24 hr before the test can falsely elevate results.
- Ingestion of drugs that alter cholesterol levels within 12 hr of the test may give a false impression of cholesterol levels, unless the test is done to evaluate such effects.

- Positioning can affect results; lower levels are obtained if the specimen is from a patient who has been supine for 20 min.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess and monitor risk for coronary artery disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular, gastrointestinal, hematopoietic, and hepatobiliary systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures. The presence of other risk factors, such as family history of heart disease, smoking, obesity, diet, lack of physical activity, hypertension, diabetes, previous myocardial...
infarction, and previous vascular disease, should be investigated.

- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to withhold alcohol and drugs known to alter cholesterol levels for 12 to 24 hr before specimen collection, at the direction of the health care provider (HCP).
- There are no fluid or medication restrictions unless by medical direction.
- Fasting 6 to 12 hr before specimen collection is required if triglyceride measurements are included; it is recommended if cholesterol levels alone are measured for screening. Protocols may vary from facility to facility.

**INTRATEST:**

- Ensure that the patient has complied with dietary restrictions and pretesting preparations; assure that food has been restricted for at least 6 to 12 hr prior to the procedure if triglycerides are to be measured.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet as directed by the HCP.
- Secondary causes for increased cholesterol levels should be ruled out before therapy to decrease levels is initiated by use of drugs.
- Nutritional considerations: Increases in total cholesterol levels may be associated with CAD. Nutritional therapy is recommended for patients identified to be at high risk for developing CAD. If overweight, the patient should be encouraged to achieve a normal weight. The American Heart Association Step 1 and Step 2 diets may be helpful in achieving a goal of lowering total cholesterol and triglyceride levels. The Step 1 diet emphasizes a reduction in foods high in saturated fats and cholesterol. Red meats, eggs, and dairy products are the major sources of saturated fats and cholesterol. If triglycerides are also elevated, the patient should be advised to eliminate or reduce alcohol and simple carbohydrates from the diet. The Step 2 diet recommends stricter reductions.
- Social and cultural considerations: Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight-control education.
- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling.
Chromosome Analysis, Blood

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Whole blood (2 mL) collected in green-top (sodium heparin) tube.

**REFERENCE VALUE:** (Method: Tissue culture and microscopic analysis) No chromosomal abnormalities identified.

**DESCRIPTION:** Testing for birth defects as well as mental and physical retardation can be accomplished through the use of several technologies. Chromosome analysis by phytohemagglutination assay is used to detect Down syndrome and abnormal sexual development. Fluorescence in situ hybridization (FISH) testing is useful in the detection of specific microdeletion syndromes (e.g., Prader-Willi, Angelman, Beckwith-Wiedemann, Smith-Magenis, DiGeorge, Williams, Miller-Dieker) and other acquired chromosomal changes associated with hematologic disorders. Amniotic fluid, chorionic villus sampling, and cells from fetal tissue or products of conception can also be evaluated for chromosomal abnormalities.

**INDICATIONS:**
- Evaluate conditions related to cryptorchidism, hypogonadism, primary amenorrhea, and infertility
- Evaluate congenital anomaly, delayed development (physical or

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate suspected chromosomal disorders.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s reproductive system, family history of known or suspected genetic disorders, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of the sensitive nature of the testing. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Social and cultural considerations: Encourage the family to seek counseling if they are contemplating pregnancy termination or to seek genetic counseling if a chromosomal abnormality is determined. Decisions regarding elective abortion should occur in the presence of both parents. Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks and difficulties of delivering and raising a developmentally challenged infant, as well as exploring other options (termination of pregnancy or adoption). It is also important to discuss feelings the mother and father may experience (e.g., guilt, depression, anger) if fetal abnormalities are detected. Educate the patient and family regarding access to counseling services, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Clot Retraction

SYNONYM/ACRONYM: N/A.

SPECIMEN: Whole blood collected in a full 5-mL red-top tube.

REFERENCE VALUE: (Method: Macroscopic observation of sample) A normal clot, gently separated from the side of the test tube and incubated at 37°C shrinks to about half of its original size within 1 hr. The result is a firm, cylindrical fibrin clot that contains red blood cells and is sharply demarcated from the clear serum. Complete clot retraction can take 6 to 24 hr.

DESCRIPTION: The clot retraction test measures the adequacy of platelet function by measuring the speed and extent of clot retraction. Normally, when blood clots in a test tube, it retracts away from the sidewalls of the tube. Platelets play a major role in the clot retraction process. When platelets are decreased or function is impaired, scant serum and a soft, plump, poorly demarcated clot form in the tube. In addition to normal platelets, clot retraction depends on the contractile protein thrombothenin, magnesium, adenosine triphosphate (ATP), and pyruvate kinase. Clot retraction is also influenced by hematocrit and by fibrinogen structure and concentration.

INDICATIONS:
- Evaluate the adequacy of platelet function
- Evaluate thrombocytopenia of unknown origin
- Investigate the possibility of Glanzmann’s disease
- Investigate suspected abnormalities of fibrinogen or fibrinolytic activity

RESULT:
Increased in: N/A.
Decreased in: Glanzmann’s thrombasthenia

CRITICAL VALUES: N/A.

INTERFERING FACTORS:
- Drugs that may produce a decreased result include apronalide, carbenicillin, and plicamycin.
- Platelet count less than 100 × 10^3/mm^3, acetylsalicylic acid

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor changes in health status and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.
therapy, altered fibrinogen/fibrin structure, hypofibrinogenemia, polycythemia or hemoconcentration, and multiple myeloma are conditions in which abnormal clot retraction may occur, limiting the ability to form a valid assessment of platelet function.
• Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results. Specimens received in the laboratory more than 1 hr after collection should be rejected.

NURSING IMPLICATIONS AND PROCEDURE
PRETEST:

➤ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➤ Inform the patient that the test is used to assist in the diagnosis of bleeding disorders.
➤ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
➤ Obtain a history of the patient's hematopoietic system and results of previously performed laboratory tests and diagnostic and surgical procedures.
➤ Note any recent procedures that can interfere with test results.
➤ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals.
➤ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
➤ Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
➤ There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

➤ If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

POST-TEST:

➤ A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
➤ Inform the patient with abnormal clot retraction of the importance of taking precautions against bruising and bleeding. These precautions may include the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of acetylsalicylic acid and similar products, and avoidance of intramuscular injections.
➤ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
➤ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

➤ Related tests include bleeding time, coagulation factor XIII, complete blood count, complete blood count hemoglobin, and complete blood count platelet count and fibrinogen.
➤ Refer to the Hematopoietic System table at the end of the book for related tests by body system.
Coagulation Factors

SYNONYM/ACRONYM: See table.

SPECIMEN: Whole blood in a completely filled 5-mL blue-top (sodium citrate) tube.

REFERENCE VALUE: (Method: Photo-optical clot detection) Activity from 50% to 150%.

DESCRIPTION: The coagulation proteins respond to blood vessel injury in a chain of events. The intrinsic and extrinsic pathways of secondary hemostasis are a series of reactions involving the substrate protein fibrinogen, the coagulation factors (also known as enzyme precursors or zymogens), nonenzymatic cofactors (Ca^{2+}), and phospholipids. The factors were assigned Roman numerals in the order of their discovery, not their place in the coagulation sequence. Factor VI was originally thought to be a
separate clotting factor. It was subsequently proved to be the same as a modified form of Factor V, and therefore the number is no longer used.

The coagulation factors are formed in the liver. They can be divided into three groups based on their common properties:

1. The contact group is activated in vitro by a surface such as glass and is activated in vivo by collagen. The contact group includes factor XI, factor XII, prekallikrein, and high-molecular-weight kininogen.

2. The prothrombin or vitamin K–dependent group includes factors II, VII, IX, and X.

3. The fibrinogen group includes factors I, V, VIII, and XIII. They are the most labile of the factors and are consumed during the coagulation process. The factors listed in the table are the ones most commonly measured.

**INDICATIONS:**
- Identify the presence of inherited bleeding disorders
- Identify the presence of qualitative or quantitative factor deficiency

**RESULT:**

**Increased in:** N/A

**Decreased in:**
- Congenital deficiency
- Disseminated intravascular coagulation (Factors are consumed as part of the coagulation cascade)
- Liver disease (Many coagulation factors are synthesized by the liver)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase factor II levels include fluoxymesterone, methandrostenolone, nandrolone, and oxymetholone.
- Drugs that may decrease factor II levels include warfarin.
- Drugs that may increase factor V, VII, and X levels include anabolic steroids, fluoxymesterone, methandrostenolone, nandrolone, oral contraceptives, and oxymetholone.
- Drugs that may decrease factor V levels include streptokinase.
- Drugs that may decrease factor VII levels include acetylsalicylic acid, asparaginase, cefamandole, ceftriaxone, dextran, dicumarol, gemfibrozil, oral contraceptives, and warfarin.
- Drugs that may increase factor VIII levels include chlormadinone.
- Drugs that may decrease factor VIII levels include asparaginase.
- Drugs that may increase factor IX levels include chlormadinone and oral contraceptives.
- Drugs that may decrease factor IX levels include asparaginase and warfarin.
- Drugs that may decrease factor X levels include chlormadinone, dicumarol, oral contraceptives, and warfarin.
- Drugs that may decrease factor XI levels include asparaginase and captopril.
- Drugs that may decrease factor XII levels include captopril.
- Test results of patients on anticoagulant therapy are unreliable.
- Placement of tourniquet for longer than 1 min can result in venous stasis and changes in the concentration of plasma proteins to be measured. Platelet activation may also occur under these conditions, causing erroneous results.
- Vascular injury during phlebotomy can activate platelets and coagulation factors, causing erroneous results.
• Hemolyzed specimens must be rejected because hemolysis is an indication of platelet and coagulation factor activation.
• Icteric or lipemic specimens interfere with optical testing methods, producing erroneous results.
• Incompletely filled collection tubes, specimens contaminated with heparin, clotted specimens, or unprocessed specimens not delivered to the laboratory within 1 hr of collection should be rejected.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to detect factor deficiencies and related coagulopathies.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic and hepatobiliary systems, any bleeding disorders, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications. Include anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

**INTRATEST:**
- There are no food, fluid, or medication restrictions unless by medical direction.

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. *Important note:* Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It is important to inquire from the laboratory which concentration it recommends, because each concentration will have its own specific reference range. When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and red-top tubes. When coagulation testing is the only work to be done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with tissue thromboplastin.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed samples stored in unopened tubes is that testing should be completed within 1 to 4 hr of collection.

- Hemolyzed specimens must be rejected because hemolysis is an indication of platelet and coagulation factor activation.

- Icteric or lipemic specimens interfere with optical testing methods, producing erroneous results.

- Incompletely filled collection tubes, specimens contaminated with heparin, clotted specimens, or unprocessed specimens not delivered to the laboratory within 1 hr of collection should be rejected.
Cold Agglutinin Titer

SYNONYM/ACRONYM: Mycoplasma serology.

SPECIMEN: Serum (2 mL) collected in a red-top tube. The tube must be placed in a water bath or heat block at 37°C for 1 hr and allowed to clot before the serum is separated from the red blood cells (RBCs).

REFERENCE VALUE: (Method: Patient serum containing autoantibodies titered against type O RBCs at 2°C to 8°C. Type O cells are used because they have no antigens on the cell membrane surface. Agglutination with patient sera would not occur because of reaction between RBC blood type antigens and patient blood type antibodies.) Negative: Single titer less than 1:32 or less than a fourfold increase in titer over serial samples.

DESCRIPTION: Cold agglutinins are antibodies that cause clumping or agglutination of RBCs at cold temperatures in individuals with certain conditions or who are infected by particular organisms. Cold agglutinins are associated with Mycoplasma pneumoniae infection. M. pneumoniae has I antigen specificity to human RBC membranes. Fetal cells largely.

Access additional resources at davisplus.fadavis.com
contain I antigens, but by 18 mo most cells carry the I antigen. The agglutinins are usually immunoglobulin M (IgM) antibodies and cause agglutination of cells at temperatures in the range of 0°C to 10°C. The temperature of circulating blood in the extremities may be lower than core temperatures. RBCs of affected individuals may agglutinate and obstruct blood vessels in fingers, toes, and ears, or they may initiate the complement cascade. Affected cells may be lysed immediately within the capillaries and blood vessels as a result of the action of complement on the cell wall, or they may return to the circulatory system and be lysed in the spleen by macrophages.

The titer endpoint is the highest dilution of serum that shows a specific antigen-antibody reaction. Single titers greater than 1:64, or a fourfold increase in titer between specimens collected 5 or more days apart, are clinically significant. Patients affected with primary atypical viral pneumonia exhibit a rise in titer 8 to 10 days after the onset of illness. IgM antibodies peak in 12 to 25 days and begin to diminish 30 days after onset.

**RESULT:**

**Increased in:**
- Infectious mononucleosis
- Malaria
- *M. pneumoniae* (primary atypical pneumonia)
- Multiple myeloma
- Raynaud’s disease (severe)
- Systemic lupus erythematosus
- Trypanosomiasis

**Decreased in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Antibiotic use may interfere with or decrease antibody production.
- A high antibody titer may interfere with blood typing and crossmatching procedures.
- High titers may appear spontaneously in elderly patients and persist for many years.
- Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results. Specimens should always be transported to the laboratory as quickly as possible after collection. The specimen must clot in a 37°C water bath for 1 hr before separation. Refrigeration of the sample before serum separates from the RBCs may falsely decrease the titer.

**INDICATIONS:**
- Assist in the confirmation of primary atypical pneumonia, influenza, or pulmonary embolus
- Provide additional diagnostic support for cold agglutinin disease associated with viral infections or lymphoreticular cancers

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of primary atypical pneumonia.
atypical pneumonia and other viral/infectious diseases.

- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune and respiratory systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Note any recent medications that can interfere with test results.
- Review the procedure with the patient. Inform the patient that multiple specimens may be required. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions (except antibiotics) unless by medical direction.

**INTRATEST:**

- Ensure that the patient has complied with medication restrictions prior to the procedure.
- If the patient has a history of an allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.
- Inform the laboratory if the patient is receiving antibiotics.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume antibiotics as directed by the HCP.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Emphasize the need for the patient to return in 7 to 14 days for a convalescent blood sample. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include arterial/alveolar oxygen ratio, blood gases, chest x-ray, complete blood count, complete blood count WBC count, Coombs’ antiglobulin, culture viral, ESR, gallium scan, infectious mononucleosis screen, lung perfusion scan, plethysmography, and pleural fluid analysis.
- Refer to the Immune and Respiratory System tables at the end of the book for related tests by body system.
**Collagen Cross-Linked N-Telopeptide**

**SYNONYM/ACRONYM:** NT$_x$.

**SPECIMEN:** Urine (2 mL) from a random specimen collected in a clean plastic container.

**REFERENCE VALUE:** (Method: Immunoassay)

**DESCRIPTION:** Osteoporosis is the most common bone disease in the West. It is often called the “silent disease” because bone loss occurs without symptoms. The formation and maintenance of bone mass is dependent on a combination of factors that include genetics, nutrition, exercise, and hormone function. Normally, the rate of bone formation is equal to the rate of bone resorption. After midlife, the rate of bone loss begins to increase. Osteoporosis is more commonly identified in women than in men. Other risk factors include thin, small-framed body structure; family history of osteoporosis; diet low in calcium; white or Asian race; excessive use of alcohol; cigarette smoking; sedentary lifestyle; long-term use of corticosteroids, thyroid replacement medications, or antiepileptics; history of bulimia, anorexia nervosa, chronic liver disease, or malabsorption disorders; and postmenopausal state. Osteoporosis is a major consequence of menopause in women owing to the decline of estrogen production. Osteoporosis is rare in premenopausal women.

Estrogen replacement therapy (after menopause) is one strategy that has been commonly employed to prevent osteoporosis, although its exact protective mechanism is unknown. Results of some recently published studies indicate that there may be significant adverse side effects to estrogen replacement therapy; more research is needed to understand the long-term effects (positive and negative) of this therapy. Other treatments include raloxifene (selectively modulates estrogen receptors), calcitonin (interacts directly with osteoclasts), and bisphosphates (inhibit osteoclast-mediated bone resorption).

A noninvasive test to detect the presence of collagen cross-linked N-telopeptide (NT$_x$) is used to follow the progress of patients who have begun treatment for osteoporosis. NT$_x$ is formed when collagenase acts on bone. Small NT$_x$ fragments are excreted in the urine after bone resorption. A desirable response, 2 to 3 mo after therapy is initiated, is a 30% reduction in NT$_x$ and a reduction of 50% below baseline by 12 mo.
**INDICATIONS:**
- Assist in the evaluation of osteoporosis
- Assist in the management and treatment of osteoporosis
- Monitor effects of estrogen replacement therapy

**RESULT:**

**Increased in:**
- Hyperparathyroidism *(Imbalance in calcium and phosphorus that affects the rate of bone resorption)*
- Osteomalacia *(Increased bone turnover related to defective bone mineralization)*
- Osteoporosis *(Increased bone turnover)*
- Paget’s disease *(Increased bone resorption; more calcium coming out of bone than being returned)*

**Decreased in:**
- Effective therapy for osteoporosis

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- NTx levels are affected by urinary excretion, and values may be influenced by the presence of renal impairment or disease.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of osteoporosis and evaluation of therapy.
- Obtain a history of the patient’s complaints, including a list of known allergens.
- Obtain a history of the patient’s musculoskeletal and reproductive systems and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there should be no discomfort during the procedure.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.
- Instruct the patient to collect a second-void morning specimen as follows: (1) void and then drink a glass of water; (2) wait 30 min, and then try to void again.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.
- Dietary considerations: Increased NTx levels may be associated with osteoporosis. Nutritional therapy may be indicated for patients identified as being at high risk for developing osteoporosis. Educate the patient about the National Osteoporosis Foundation’s guidelines regarding a regular regimen of weight-bearing exercises, limited
alcohol intake, avoidance of tobacco products, and adequate dietary intake of vitamin D (400 to 800 IU/d) and calcium (1200 to 1500 mg/d). Dietary calcium can be obtained in animal or plant sources. Milk and milk products, sardines, clams, oysters, salmon, rhubarb, spinach, beet greens, broccoli, kale, tofu, legumes, and fortified orange juice are high in calcium. Milk and milk products also contain vitamin D and lactose to assist in absorption. Cooked vegetables yield more absorbable calcium than raw vegetables. Patients should also be informed of the substances that can inhibit calcium absorption by irreversibly binding to some of the calcium and making it unavailable for absorption, such as oxalates, which naturally occur in some vegetables; phytic acid, found in some cereals; and excessive intake of insoluble dietary fiber. Excessive protein intake also can affect calcium absorption negatively, especially if it is combined with foods high in phosphorus. Vitamin D is synthesized by the skin and is available in fortified dairy foods and cod liver oil.

Recognize anxiety related to test results, and be supportive of impaired activity related to lack of muscular control, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the National Osteoporosis Foundation (www.nof.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ALP, BMD, calcitonin, calcium, creatinine, creatinine clearance, osteocalcin, PTH, phosphorus, radiography bone, and vitamin D.
- Refer to the Musculoskeletal and Reproductive System tables at the end of the book for related tests by body system.

**Colonoscopy**

**SYNONYM/ACRONYM:** Full colonoscopy, lower endoscopy, lower panendoscopy.

**AREA OF APPLICATION:** Colon.

**CONTRAST:** Air.

**DESCRIPTION:** Colonoscopy allows inspection of the mucosa of the entire colon, ileocecal valve, and terminal ileum using a flexible fiberoptic colonoscope inserted through the anus and advanced to the terminal ileum. The colonoscope is a multichannel...
COLONOSCOPY

Instrument that allows viewing of the gastrointestinal (GI) tract lining, insufflation of air, aspiration of fluid, obtaining of tissue biopsy samples, and passage of a laser beam for obliteration of tissue and control of bleeding. Mucosal surfaces of the lower GI tract are examined for ulcerations, polyps, chronic diarrhea, hemorrhagic sites, neoplasms, and strictures. During the procedure, tissue samples may be obtained for cytology, and some therapeutic procedures may be performed, such as excision of small tumors or polyps, coagulation of bleeding sites, and removal of foreign bodies.

INDICATIONS:
- Assess GI function in a patient with a personal or family history of colon cancer, polyps, or ulcerative colitis
- Confirm diagnosis of colon cancer and inflammatory bowel disease
- Detect Hirschsprung’s disease and determine the areas affected by the disease
- Determine cause of lower GI disorders, especially when barium enema and proctosigmoidoscopy are inconclusive
- Determine source of rectal bleeding and perform hemostasis by coagulation
- Evaluate postsurgical status of colon resection
- Evaluate stools that show a positive occult blood test, lower GI bleeding, or change in bowel habits
- Follow up on previously diagnosed and treated colon cancer
- Investigate iron-deficiency anemia of unknown origin
- Reduce volvulus and intussusception in children
- Remove colon polyps
- Remove foreign bodies and sclerosing strictures by laser

RESULT:

Normal findings in:
- Normal intestinal mucosa with no abnormalities of structure, function, or mucosal surface in the colon or terminal ileum

Abnormal findings in:
- Benign lesions
- Bleeding sites
- Bowel distention
- Bowel infection or inflammation
- Colitis
- Colon cancer
- Crohn’s disease
- Diverticula
- Foreign bodies
- Hemorrhoids
- Polyps
- Proctitis
- Tumors
- Vascular abnormalities

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients with bleeding disorders or cardiac conditions
- Patients with bowel perforation, acute peritonitis, acute colitis, ischemic bowel necrosis, toxic colitis, recent bowel surgery, advanced pregnancy, severe cardiac or pulmonary disease, recent myocardial infarction, known or suspected pulmonary embolus, and large abdominal aortic or iliac aneurysm
- Patients who have had a colon anastomosis within the past 14 to 21 days, because an anastomosis may break down with gas insufflation
Factors that may impair clear imaging:
• Gas or feces in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study
• Retained barium from a previous radiological procedure
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
• Patients who are very obese, or who may exceed the weight limit for the equipment
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Severe lower GI bleeding or the presence of feces, barium, blood, or blood clots, which can interfere with visualization
• Spasm of the colon, which can mimic the radiographic signs of cancer (Note: the use of IV glucagon minimizes spasm)
• Inability of the patient to tolerate introduction of or retention of barium, air, or both in the bowel

Other considerations:
• Complications of the procedure may include hemorrhage and cardiac arrhythmias.
• The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
• Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
• Bowel preparations that include laxatives or enemas should be avoided in pregnant patients or patients with inflammatory bowel disease, unless specifically directed by a health care provider (HCP).
• Consultation with a HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the examination room with the patient should wear a protective lead apron or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

Nursing Implications and Procedure

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses the colon.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
• Obtain a history of patient’s GI system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
• Ensure that barium studies were performed more than 4 days before the CT scan.
• Ensure that this procedure is performed before an upper GI study or barium swallow.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.

Note intake of oral iron preparations within 1 wk before the procedure because these cause black, sticky feces that are difficult to remove with bowel preparation.

Review the procedure with the patient. Address concerns about pain and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a GI lab, by a HCP, with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Inform the patient that it is important that the bowel be cleaned thoroughly so that the physician can visualize the colon. Inform the patient that a laxative and cleansing enema may be needed the day before the procedure, with cleansing enemas on the morning of the procedure, depending on the institution’s policy.

Instruct the patient to remove all external metallic objects from the area to be examined.

Instruct the patient to eat a low-residue diet for several days before the procedure and to consume only clear liquids the evening before the test. The patient should fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

Ensure that the patient has complied with dietary, fluid and medication restrictions, and pretesting preparations for at least 8 hr prior to the procedure.

Ensure that ordered laxatives were administered late in the afternoon of the day before the procedure.

Assess for completion of bowel preparation according to the institution’s procedure.

Instruct the patient to remove all external metallic objects from the area to be examined.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate containers with the corresponding patient demographics, date, and time of collection.

Obtain and record baseline vital signs.

An IV line may be started to allow infusion of a sedative or IV fluids.

Administer medications, as ordered, to reduce discomfort and to promote relaxation and sedation.

Place the patient on an examination table in the left lateral decubitus position and drape with the buttocks exposed.

The HCP performs a visual inspection of the perianal area and a digital rectal examination.

Instruct the patient to bear down as if having a bowel movement as the fiberoptic tube is inserted through the rectum.

The scope is advanced through the sigmoid. The patient’s position is changed to supine to facilitate passage into the transverse colon. Air is insufflated through the tube during passage to aid in visualization.

Instruct the patient to take deep breaths to aid in movement of the scope downward through the ascending colon to the cecum and into the terminal portion of the ileum.
Inform the patient that belching, bloating, or flatulence is the result of air insufflation.

Emphasize that any severe pain, fever, difficulty breathing, or GI bleeding must be reported to the HCP immediately.

Encourage the patient to drink several glasses of water to help replace fluids lost during the preparation for the test.

Carefully monitor the patient for fatigue and fluid and electrolyte imbalance.

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include barium enema, biopsy intestinal, capsule endoscopy, carcinoembryonic and cancer antigens, CT abdomen, CT colonoscopy, fecal analysis, KUB, MRI abdomen, and proctosigmoidoscopy.

Refer to the Gastrointestinal System table in the back of the book for related tests by body system.
Color Perception Test

SYNONYM/ACRONYM: Color blindness test, Ishihara color perception test, Ishihara pseudoisochromatic plate test.

AREA OF APPLICATION: Eyes.

DESCRIPTION: Defects in color perception can be hereditary or acquired. The congenital defect for color blindness is carried by the female, who is generally unaffected, and is expressed dominantly in males. Color blindness occurs in 8% of males and 0.4% of females. It may be partial or complete. The partial form is the hereditary form, and in the majority of patients the color deficiency is in the red-green area of the spectrum. Acquired color blindness may occur as a result of diseases of the retina or optic nerve. Color perception tests are performed to determine the acuity of color discrimination. The most common test uses pseudoisochromic plates with numbers or letters buried in a maze of dots. Misreading the numbers or letters indicates a color perception deficiency and may indicate color blindness, a genetic dysfunction, or retinal pathology.

RESULT:

Normal findings in:
- Normal visual color discrimination; no difficulty in identification of color combinations

Abnormal findings in:
- Identification of some but not all colors

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Inability of the patient to read
- Poor visual acuity or poor lighting
- Failure of the patient to wear corrective lenses (glasses or contact lenses)
- Damaged or discolored test plates

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure detects color vision impairment.
- Obtain a history of the patient’s complaints, including a list of known allergens.
- Obtain a history of the patient’s known or suspected vision loss.

Access additional resources at davisplus.fadavis.com
changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.

- Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Ask the patient if he or she wears corrective lenses; also inquire about the importance of color discrimination in his or her work, as applicable. Address concerns about pain and explain that no discomfort will be experienced during the test.
- Inform the patient that a health care provider (HCP) performs the test in a quiet, darkened room, and that to evaluate both eyes, the test can take 5 to 15 or up to 30 min, depending on the complexity of testing required.

*Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**

- Instruct the patient to cooperate fully and to follow directions.
- Seat the patient comfortably. Occlude one eye and hold test booklet 12 to 14 in. in front of the exposed eye.
- Ask the patient to identify the numbers or letters buried in the maze of dots or to trace the objects with a hand-held pointed object.
- Repeat on the other eye.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Recognize anxiety related to test results and be supportive of impaired activity related to color vision loss. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information regarding vision aids for people with impaired color perception, if desired—ABLEDATA (sponsored by the National Institute on Disability and Rehabilitation Research [NIDRR], available at www.abledata.com).
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include refraction and slit-lamp biomicroscopy.
- Refer to the Ocular System table in the back of the book for related tests by body system.
Colposcopy

SYNONYM/ACRONYM: Endometrial biopsy, cervical biopsy.

AREA OF APPLICATION: Vagina and cervix.

CONTRAST: None.

DESCRIPTION: In this procedure, the vagina and cervix are viewed using a colposcope, a special binocular microscope and light system that magnifies the mucosal surfaces. Colposcopy is usually performed after suspicious Papanicolaou (Pap) test results or when suspected lesions cannot be visualized fully by the naked eye. The procedure is useful for identifying areas of cellular dysplasia and diagnosing cervical cancer because it provides the best view of the suspicious lesion, ensuring that the most representative area of the lesion is obtained for cytological analysis to confirm malignant changes. Colposcopy is also valuable for assessing women with a history of exposure to diethylstilbestrol (DES) in utero. The goal is to identify precursor changes in cervical tissue before the changes advance from benign or atypical cells to cervical cancer. Photographs (cervicography) can also be taken of the cervix.

INDICATIONS:
- Evaluate the cervix after abnormal Pap smear
- Evaluate vaginal lesions
- Localize the area from which cervical biopsy samples should be obtained because such areas may not be visible to the naked eye
- Monitor conservatively treated cervical intraepithelial neoplasia
- Monitor women whose mothers took DES during pregnancy

RESULT:
Normal findings in:
- Normal appearance of the vagina and cervix
- No abnormal cells or tissues

Abnormal findings in:
- Atrophic changes
- Cervical erosion
- Cervical intraepithelial neoplasia
- Infection
- Inflammation
- Invasive carcinoma
- Leukoplakia
- Papilloma, including condyloma

CRITICAL VALUES: N/A

INTERFERING FACTORS:
This procedure is contraindicated for:
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
- Patients with cardiac conditions
- Patients with bleeding disorders, especially if cervical biopsy specimens are to be obtained
- Women who are currently menstruating

Access additional resources at davisplus.fadavis.com
Factors that may impair clear imaging:
- Inadequate cleansing of the cervix of secretions and medications
- Scarring of the cervix
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Severe bleeding or the presence of feces, blood, or blood clots, which can interfere with visualization

Other considerations:
- Complications of the procedure may include hemorrhage and cardiac arrhythmias.
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the uterus and cervix.
- Obtain a history of the patient’s complaints including a list of known allergens, especially allergies or sensitivities to latex, iodine, or anesthetics.
- Obtain a history of results of the patient’s reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.

INTRATEST:
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed by a health care provider (HCP), with support staff, and takes approximately 30 to 60 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain to the patient that if a biopsy is performed, she may feel menstrual-like cramping during the procedure and experience a minimal amount of bleeding.
- There are no food, fluid, or medication restrictions unless by medical direction.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate containers with the corresponding patient demographics, date, and time of collection.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Obtain and record baseline vital signs. An IV line may be started to allow infusion of a sedative or IV fluids.
- Administer medications, as ordered, to reduce discomfort and to promote relaxation and sedation.
- Place the patient in the lithotomy position on the examining table and drape her. Cleanse the external genitalia with an antiseptic solution.
- If a Pap smear is performed, the vaginal speculum is inserted, using water as a lubricant.
The cervix is swabbed with 3% acetic acid to remove mucus or any cream medication and to improve the contrast between tissue types. The scope is positioned at the speculum and is focused on the cervix. The area is examined carefully, using light and magnification. Photographs can be taken for future reference.

Tissues that appear abnormal or atypical undergo biopsy using a forceps inserted through the speculum. Bleeding, which is common after cervical biopsy, may be controlled by cautery, suturing, or application of silver nitrate or ferric subsulfate (Monsel’s solution) to the site.

The vagina is rinsed with sterile saline or water to remove the acetic acid and prevent burning after the procedure. If bleeding persists, a tampon may be inserted after removal of the speculum.

Biopsy samples are placed in appropriately labeled containers with special preservative solution, and promptly transported to the laboratory.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Monitor the patient for signs of respiratory depression.
- Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Observe the patient until the effects of the sedation, if ordered, have worn off.
- Instruct the patient to remove the vaginal tampon, if inserted, within 8 to 24 hr; after that time, the patient should wear pads if there is bleeding or drainage.

If a biopsy was performed, inform the patient that a discharge may persist for a few days to a few weeks.

Advise the patient to avoid strenuous exercise 8 to 24 hr after the procedure, and to avoid douching and intercourse for about 2 wk or as directed by the HCP.

Monitor for any bleeding.

Instruct the patient to expect slight bleeding for 2 days after removal of biopsy specimens, but emphasize that persistent vaginal bleeding or abnormal vaginal discharge, an increasing amount of bleeding, abdominal pain, and fever must be reported to the HCP immediately.

Observe the patient for indications of chest pain, abdominal pain or tenderness, or breathing problems. If symptoms are present or increase in frequency or severity, the change should be reported to the HCP immediately.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include biopsy cervical, CT abdomen, culture viral, MRI abdomen, PAP smear, and US pelvis.
- Refer to the Reproductive System table at the back of the book for related tests by body system.

**Description:** Complement proteins act as enzymes that aid in the immunological and inflammatory response. The complement system is an important mechanism for the destruction and removal of foreign materials. Serum complement levels are used to detect autoimmune diseases. C3 and C4 are the most frequently assayed complement proteins, along with total complement.

Circulating C3 is synthesized in the liver and comprises 70% of the complement system, but cells in other tissues can also produce C3. C3 is an essential activating protein in the classic and alternate complement cascades. It is decreased in patients with immunological diseases, in whom it is consumed at an increased rate. C4 is produced primarily in the liver but can also be produced by monocytes, fibroblasts, and macrophages. C4 participates in the classic complement pathway.

**Indications:**
- Detect genetic deficiencies
- Evaluate immunological diseases
### Increased in:
**Response to sudden increased demand.**
- C3 and C4
  - Acute-phase reactions
- C3
  - Amyloidosis
  - Cancer
  - Diabetes
  - Myocardial infarction
  - Pneumococcal pneumonia
  - Pregnancy
  - Rheumatic disease
  - Thyroiditis
  - Viral hepatitis
- C4
  - Certain malignancies

### Decreased in:
**Related to overconsumption during immune response.**
- C3 and C4
  - Hereditary deficiency (Insufficient production)
  - Liver disease (Insufficient production related to damaged liver cells)
  - Systemic lupus erythematosus (SLE)
- C3
  - Chronic infection (bacterial, parasitic, viral)
  - Post–membranoproliferative glomerulonephritis
  - Post–streptococcal infection
  - Rheumatic arthritis
- C4
  - Angioedema (hereditary and acquired)
  - Autoimmune hemolytic anemia
  - Autoimmune thyroiditis
  - Cryoglobulinemia
  - Glomerulonephritis

<table>
<thead>
<tr>
<th>Normal C4 and decreased C3</th>
<th>Acute glomerulonephritis, membranous glomerulonephritis, immune complex diseases, SLE, C3 deficiency</th>

<td>Immune complex diseases</td>
</tr>
</tbody>
</table>

| **CRITICAL VALUES:** | N/A |

**INTERFERING FACTORS:**
- Drugs that may increase C3 levels include cimetidine and cyclophosphamide.
- Drugs that may decrease C3 levels include danazol and phenytoin.
- Drugs that may increase C4 levels include cimetidine, cyclophosphamide, and danazol.
- Drugs that may decrease C4 levels include dextran and penicillamine.

### PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of immunological diseases in which complement is consumed at an increased rate or to detect inborn deficiency.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune system and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Access additional resources at davisplus.fadavis.com
Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include anticardiolipin antibody, ANA, complement total, cryoglobulin, and ESR.
- Refer to the Immune System table at the end of the book for related tests by body system.

**SYNONYM/ACRONYM:** Total hemolytic complement, CH<sub>50</sub>, CH<sub>100</sub>.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**DESCRIPTION:** The complement system comprises proteins that become activated and interact in a sequential cascade. The complement system is an important part of the body’s natural defense against allergic and immune reactions. It is activated by plasmin and is interrelated with the coagulation and fibrinolytic systems. Activation of the complement system results in cell lysis, release of histamine, chemotaxis of white blood cells, increased vascular permeability, and contraction of smooth muscle. The activation of this system can sometimes occur with uncontrolled self-destructive effects on the body. In the serum complement assay, a patient’s serum is mixed with sheep red blood cells coated with antibodies. If complement is present in sufficient quantities, 50% of the red blood cells are lysed. Lower amounts of lysed cells are associated with decreased complement levels.

**INDICATIONS:**
- Assist in the diagnosis of hereditary angioedema
- Evaluate complement activity in autoimmune disorders
- Evaluate and monitor therapy for systemic lupus erythematosus (SLE)
- Screen for complement deficiency

**RESULT:**

*Increased in:*
- Acute-phase immune response *(Response to sudden increased demand)*

*Decreased in:*
- Autoimmune diseases *(Related to continuous demand)*
- Autoimmune hemolytic anemia *(Related to consumption during hemolytic process)*
- Burns *(Increased consumption from initiation of complement cascade)*
- Cryoglobulinemia *(Related to increased consumption)*
- Hereditary deficiency *(Insufficient production)*
- Infections *(Bacterial, parasitic, viral; increased consumption during immune response)*
- Liver disease *(Related to decreased production by damaged liver cells)*
- Malignancy *(Related to consumption during cellular immune response)*
- Membranous glomerulonephritis *(Related to consumption during cellular immune response)*
- Rheumatoid arthritis *(Related to consumption during immune response)*
- SLE *(Related to consumption during immune response)*
- Trauma *(Related to consumption during immune response)*
- Vasculitis *(Related to consumption during cellular immune response)*

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase total complement levels include cyclophosphamide and danazol.
- Specimen should not remain at room temperature longer than 1 hr.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate immune diseases related to complement activity and follow up on a patient’s response to therapy.
- Obtain a history of the patient’s complaints, including a list of
known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient’s immune system and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage. Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include antibody anticytoplasmic neutrophilic, ANA, Coomb’s antiglobulin, complement C3 and C4, cryoglobulin, ESR, G6PD, Ham’s test, osmotic fragility, PK, RF.
- Refer to the Immune System table at the end of the book for related tests by body system.

**SYNONYM/ACRONYM:** CBC.

**SPECIMEN:** Whole blood from one full lavender-top (EDTA) tube or Microtainer. Whole blood from a green-top (lithium or sodium heparin) tube may be submitted, but the following automated values may not be reported: white blood cell (WBC) count, WBC differential, platelet count, and mean platelet volume.
REFERENCE VALUE: (Method: Automated, computerized multichannel analyzers that sort and size cells on the basis of changes in either electrical impedance or light pulses as the cells pass in front of a laser. Many of these analyzers are capable of determining a five-part WBC differential.) This battery of tests includes hemoglobin, hematocrit, red blood cell (RBC) count, RBC morphology, RBC indices, RBC distribution width index (RDW), platelet count, platelet size, WBC count, and WBC differential. The five-part automated WBC differential identifies and enumerates neutrophils, lymphocytes, monocytes, eosinophils, and basophils.

DESCRIPTION: A complete blood count (CBC) is a group of tests used for basic screening purposes. It is probably the most widely ordered laboratory test. Results provide the enumeration of the cellular elements of the blood, measurement of RBC indices, and determination of cell morphology by automation and evaluation of stained smears. The results can provide valuable diagnostic information regarding the overall health of the patient and the patient’s response to disease and treatment. Detailed information is found in monographs titled “Complete Blood Count, Hemoglobin,” “Complete Blood Count, Hematocrit,” “Complete Blood Count, RBC Indices,” “Complete Blood Count, Red Blood Cell Indices,” “Complete Blood Count, Red Blood Cell Morphology and Inclusions,” “Complete Blood Count, Red Blood Cell Count,” “Complete Blood Count, Platelet Count,” and “Complete Blood Count, White Blood Cell Count and Cell Differential.”

INDICATIONS:
- Detect hematologic disorder, neoplasm, leukemia, or immunologic abnormality
- Determine the presence of hereditary hematologic abnormality
- Evaluate known or suspected anemia and related treatment
- Monitor blood loss and response to blood replacement
- Monitor the effects of physical or emotional stress
- Monitor fluid imbalances or treatment for fluid imbalances
- Monitor hematologic status during pregnancy
- Monitor progression of nonhematologic disorders, such as chronic obstructive pulmonary disease, malabsorption syndromes, cancer, and renal disease
- Monitor response to chemotherapy and evaluate undesired reactions to drugs that may cause blood dyscrasias
- Provide screening as part of a general physical examination, especially on admission to a health care facility or before surgery

Increased in:
See above-listed monographs.

Decreased in:
See above-listed monographs.

CRITICAL VALUES:

Hemoglobin:
- Less than 6 g/dL
- Greater than 18 g/dL

Hematocrit:
- Less than 18%
- Greater than 54%

WBC count (on admission):
- Less than 2500/mm³
- Greater than 30,000/mm³

Platelet count:
- Less than 20,000/mm³
- Greater than 1,000,000/mm³

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms. The presence of abnormal cells, other morphologic characteristics, or cellular inclusions may signify a potentially life-threatening or serious
health condition and should be investigated. Examples are the presence of sickle cells, moderate numbers of spherocytes, marked schistocytosis, oval macrocytes, basophilic stippling, eosinophil count greater than 10%, monocytosis greater than 15%, nucleated RBCs (if patient is not an infant), malarial organisms, hypersegmented neutrophils, agranular neutrophils, blasts or other immature cells, Auer rods, Döhle bodies, marked toxic granulation, or plasma cells.

**INTERFERING FACTORS:**
- Failure to fill the tube sufficiently (less than three-fourths full) may yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.
- Hemolyzed or clotted specimens should be rejected for analysis.
- Elevated serum glucose or sodium levels may produce elevated mean corpuscular volume values because of swelling of erythrocytes.
- Recent transfusion history should be considered when evaluating the CBC.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. An EDTA Microtainer sample may be obtained from infants, children, and adults for whom venipuncture may not be feasible. The specimen should be analyzed within 6 hr when stored at room temperature or within 24 hr if stored at refrigerated temperature. If it is anticipated that the specimen will not be analyzed within 4 to 6 hr, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 6 hr will contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and spherocytes, as well as necrobiotic WBCs.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate numerous conditions involving red blood cells, white blood cells, and platelets. The test is also used to indicate inflammation, infection, and response to chemotherapy.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s gastrointestinal, hematopoietic, immune, and respiratory systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.
COMPLETE BLOOD COUNT, HEMATOCRIT

POST-TEST:

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- **Nutritional considerations:** Instruct patients to consume a variety of foods within the basic food groups, maintain a healthy weight, be physically active, limit salt intake, limit alcohol intake, and avoid use of tobacco.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include alveolar arterial ratio, biopsy bone marrow, blood gases, blood groups and antibodies, erythropoietin, ferritin, complete blood count hematocrit, complete blood count hemoglobin, iron/TIBC, lead, complete blood count platelet count, pulse oximetry, complete blood count RBC count, complete blood count RBC indices, complete blood count RBC morphology, reticulocyte count, and complete blood count WBC count and cell differential.
- Refer to the Gastrointestinal, Genitourinary, Hematopoietic, Immune, and Respiratory System tables at the end of the book for related tests by body system.

SYNONYM/ACRONYM: Packed cell volume (PCV), Hct.

SPECIMEN: Whole blood from one full lavender-top (EDTA) tube, Microtainer, or capillary. Whole blood from a green-top (lithium or sodium heparin) tube may also be submitted.

REFERENCE VALUE: (Method: Automated, computerized, multichannel analyzers)

DESCRIPTION: Blood consists of a fluid portion (plasma) and a solid portion that includes red blood cells (RBCs), white blood cells, and platelets. The hematocrit, or packed cell volume, is the percentage of RBCs in a volume of whole blood. For example, a hematocrit (Hct) of 45% means that a 100-mL sample of blood contains 45 mL of packed RBCs. Although the Hct depends primarily on the number of RBCs, the average size of the RBCs plays a role. Conditions that cause the RBCs to swell, such as when the serum sodium concentration is elevated, may increase the Hct level.

Hct level is included in the complete blood count (CBC) and is generally tested together with hemoglobin (Hgb). These levels parallel each other and are the best determinant of the degree of anemia or polycythemia. Polycythemia is a term used in conjunction with conditions resulting from an abnormal increase in Hgb, Hct, and RBC count. Anemia is a term associated with conditions resulting from an abnormal decrease in Hgb, Hct, and RBC count. Results of the Hgb, Hct, and RBC count should be evaluated simultaneously because the same underlying conditions affect this triad of tests similarly. The RBC count multiplied by 3 should approximate the Hgb concentration. The Hct should be within three times the Hgb if the RBC population is normal in size and shape. The Hct plus 6 should approximate the first two figures of the RBC count within 3 (e.g., Hct is 40%; therefore 40 + 6 = 46, and the RBC count should be 4.6 or in the range of 4.3 to 4.9). There are some cultural variations in Hgb and Hct (H&H) values. After the first decade of life, the mean Hgb in African Americans is 0.5 to 1.0 g lower than in whites. Mexican Americans and Asian Americans have higher H&H values than whites.

INDICATIONS:
• Detect hematological disorder, neoplasm, or immunological abnormality
• Determine the presence of hereditary hematological abnormality
• Evaluate known or suspected anemia and related treatment, in combination with Hgb
• Monitor blood loss and response to blood replacement, in combination with Hgb
• Monitor the effects of physical or emotional stress on the patient
• Monitor fluid imbalances or their treatment
• Monitor hematological status during pregnancy, in combination with Hgb
• Monitor the progression of non-hematological disorders such as chronic obstructive pulmonary disease, malabsorption syndromes, cancer, and renal disease
• Monitor response to drugs or chemotherapy, and evaluate undesired reactions to drugs that may cause blood dyscrasias
• Provide screening as part of a CBC count in a general physical examination, especially upon admission to a health care facility or before surgery

RESULT:
Increased in:
• Burns (Related to dehydration; total blood volume is decreased but RBC count remains the same)
• Congestive heart failure (When the underlying cause is anemia,
the body will respond by increasing production of RBC; with a responding increase in Hct)

• COPD (Related to chronic hypoxia that stimulates production of RBC and a corresponding increase in Hct)

• Dehydration (Total blood volume is decreased but RBC count remains the same)

• Erythrocytosis (Total blood volume remains the same but RBC count is increased)

• Hemoconcentration (Same effect as seen in dehydration)

• High altitudes (Related to hypoxia that stimulates production of RBC and therefore increases Hct)

• Polycythemia (Abnormal bone marrow response resulting in overproduction of RBC)

• Shock

Decreased in:

• Anemia (Overall decrease in RBC and corresponding decrease in Hct)

• Blood loss (acute and chronic) (Overall decrease in RBC and corresponding decrease in Hct)

• Bone marrow hyperplasia (Bone marrow failure that results in decreased RBC production)

• Chronic disease (Anemia is often associated with chronic disease)

• Hemolytic disorders (Reduced RBC survival with corresponding decrease in Hct)

• Hemorrhage (acute and chronic) (Related to loss of RBC that exceeds rate of production)

• Fluid retention (Dilutional effect of increased blood volume while RBC count remains stable)

• Nutritional deficit (Anemia related to dietary deficiency in iron, vitamins, folate needed to produce sufficient RBC; decreased RBC count with corresponding decrease in Hct)

• Pregnancy (Related to anemia)

• Splenomegaly (Total blood volume remains the same but spleen retains RBCs and Hct reflects decreased RBC count)

CRITICAL VALUES:

Less than 18%
Greater than 54%

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms.

Low Hct leads to anemia. Anemia can be caused by blood loss, decreased blood cell production, increased blood cell destruction, and hemodilution. Causes of blood loss include menstrual excess or frequency, gastrointestinal bleeding, inflammatory bowel disease, and hematuria. Decreased blood cell production can be caused by folic acid deficiency, vitamin B₁₂ deficiency, iron deficiency, and chronic disease. Increased blood cell destruction can be caused by a hemolytic reaction, chemical reaction, medication reaction, and sickle cell disease. Hemodilution can be caused by congestive heart failure, renal failure, polydipsia, and overhydration. Symptoms of anemia (due to these causes) include anxiety, dyspnea, edema, hypertension, hypotension, hypoxia, jugular venous distention, fatigue, pallor, rales, restlessness, and weakness. Treatment of anemia depends on the cause.

High Hct leads to polycythemia. Polycythemia can be caused by dehydration, decreased oxygen levels in the body, and an overproduction of RBCs by the bone marrow. Dehydration from diuretic use, vomiting, diarrhea, excessive sweating, severe burns, or decreased fluid intake decreases the plasma component of whole blood, thereby
increasing the ratio of RBCs to plasma, and leads to a higher than normal Hct. Causes of decreased oxygen include smoking, exposure to carbon monoxide, high altitude, and chronic lung disease, which leads to a mild hemoconcentration of blood in the body to carry more oxygen to the body’s tissues. An overproduction of RBCs by the bone marrow leads to polycythemia vera, which is a rare chronic myeloproliferative disorder that leads to a severe hemoconcentration of blood. Severe hemoconcentration can lead to thrombosis (spontaneous blood clotting). Symptoms of hemoconcentration include decreased pulse pressure and volume, loss of skin turgor, dry mucous membranes, headaches, hepatomegaly, low central venous pressure, orthostatic hypotension, pruritis (especially after a hot bath), splenomegaly, tachycardia, thirst, tinnitus, vertigo, and weakness. Treatment of polycythemia depends on the cause. Possible interventions for hemoconcentration due to dehydration include intravenous fluids and discontinuance of diuretics if they are believed to be contributing to critically elevated Hct. Polycythemia due to decreased oxygen states can be treated by removal of the offending substance, such as smoke or carbon monoxide. Treatment includes oxygen therapy in cases of smoke inhalation, carbon monoxide poisoning, and desaturating chronic lung disease. Symptoms of polycythemic overload crisis include signs of thrombosis, pain and redness in the extremities, facial flushing, and irritability. Possible interventions for hemoconcentration due to polycythemia include therapeutic phlebotomy and intravenous fluids.

INTERFERING FACTORS:
- Drugs and substances that may cause a decrease in Hct include those that induce hemolysis due to drug sensitivity or enzyme deficiency, such as acetaminophen, aminopyrine, aminosalicylic acid, amphetamine, anticonvulsants, antimalarials, antipyretics, antipyrene, arsenicals, benzene, busulfan, carbenicillin, cephalothin, chemotherapy drugs, chlorate, chloroquine, chlorothiazide, chlorpromazine, colchicine, corticosteroids, dapsone, dimercaprol, diphenhydramine, dipyrone, glucosulfone, glycerin, gold, hydroflumethiazide, indomethacin, mephenytoin, methyldopa, nalidixic acid, neomycin, niridazole, nitrobenzene, nitrofurantoin, novobiocin, penicillin, phenacetin, phenazopyridine, phenothiazines, and pipobroman (intended effect for polycythemia); and those that result in anemia, such as miconazole, penicillamine, phenylhydrazine, primidone, probenecid, pyrazolones, pyrimethamine, quinines, streptomycin, sulfamethizole, sulfamethoxypyridazine, sulfisoxazole, suramin, thioridazine, tolbutamide, trimethadione, and tripelennamine.
- Some drugs may also affect Hct values by increasing or decreasing the RBC count (see monograph titled “Complete Blood Count, RBC Count”).
- The results of RBC counts may vary depending on the patient’s position: Hct can decrease when the patient is recumbent as a result of hemodilution and can increase when the patient rises as a result of hemoconcentration.
- Leaving the tourniquet in place for longer than 60 sec can falsely increase Hct levels by 2% to 5%.
- Traumatic venipuncture and hemolysis may result in falsely decreased Hct values.
- Failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may yield inadequate sample volume for automated analyzers.
and may be a reason for specimen rejection.

- Clotted or hemolized specimens must be rejected for analysis.
- Care should be taken in evaluating the Hct during the first few hours after transfusion or acute blood loss because the value may appear to be normal and may not be a reliable indicator of anemia.
- Abnormalities in the RBC size (macrocytes, microcytes) or shape (spherocytes, sickle cells) may alter Hct values, as in diseases and conditions including sickle cell anemia, hereditary spherocytosis, and iron deficiency.
- Elevated blood glucose or serum sodium levels may produce elevated Hct levels because of swelling of the erythrocytes.

**NURSING IMPLICATIONS AND PROCEDURE**

### PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate anemia, polycythemia, and hydration status and to monitor therapy.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular, gastrointestinal, hematopoietic, hepatobiliary, immune, musculoskeletal, and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

### INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL lavender-top (EDTA) tube. An EDTA Microtainer sample may be obtained from infants, children, and adults for whom venipuncture may not be feasible. The specimen should be mixed gently by inverting the tube 10 times. The specimen should be analyzed within 6 hr when stored at room temperature or within 24 hr if stored at refrigerated temperature. If it is anticipated the specimen will not be analyzed within 4 to 6 hr, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 6 hr will contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and spherocytes, as well as necrobiotic white blood cells.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

### POST-TEST:
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
Nutritional considerations: Nutritional therapy may be indicated for patients with decreased Hct. Iron deficiency is the most common nutrient deficiency in the United States. Patients at risk (e.g., children, pregnant women and women of childbearing age, low-income populations) should be instructed to include foods that are high in iron in their diet, such as meats (especially liver), eggs, grains, green leafy vegetables, and multivitamins with iron. Iron absorption is affected by numerous factors (see monograph titled “Iron”).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include biopsy bone marrow, complete blood count, complete blood count, hemoglobin, complete blood count, RBC indices, complete blood count, RBC morphology, erythropoietin, ferritin, iron/TIBC, and reticulocyte count.
- Refer to the Cardiovascular, Gastrointestinal, Hematopoietic, Hepatobiliary, Immune, Musculoskeletal, and Respiratory System tables at the back of the book for related tests by body system.

Complete Blood Count, Hemoglobin

SYNONYM/ACRONYM: Hgb.

SPECIMEN: Whole blood from one full lavender-top (EDTA) tube, Microtainer, or capillary. Whole blood from a green-top (lithium or sodium heparin) tube may also be submitted.

REFERENCE VALUE: (Method: Spectrophotometry)

**DESCRIPTION:** Hemoglobin (Hgb) is the main intracellular protein of erythrocytes. It carries oxygen (O₂) to and removes carbon dioxide (CO₂) from red blood cells (RBCs). It also serves as a buffer to maintain acid-base balance in the extracellular fluid. Each Hgb molecule consists of heme and globulin. Copper is a cofactor necessary for the enzymatic incorporation of iron molecules into heme. Heme contains iron and porphyrin molecules that have a high affinity for O₂. The affinity of Hgb molecules for O₂ is influenced by 2,3-diphosphoglycerate (2,3-DPG), a substance produced by anaerobic glycolysis to generate energy for the RBCs. When Hgb binds with 2,3-DPG, O₂ affinity decreases. The ability of Hgb to bind and release O₂ can be graphically represented by an oxyhemoglobin dissociation curve. The term *shift to the left* is used to describe an increase in the affinity of Hgb for O₂. Conditions that can cause this leftward shift include decreased body temperature, decreased 2,3-DPG, decreased CO₂ concentration, and increased pH. Conversely, a *shift to the right* represents a decrease in the affinity of Hgb for O₂. Conditions that can cause a rightward shift include increased body temperature, increased 2,3-DPG levels, increased CO₂ concentration, and decreased pH.

Hgb levels are a direct reflection of the O₂-combining capacity of the blood. It is the combination of heme and O₂ that gives blood its characteristic red color. RBC counts parallel the O₂-combining capacity of Hgb, but because some RBCs contain more Hgb than others, the relationship is not directly proportional. As CO₂ diffuses into RBCs, an enzyme called carbonic anhydrase converts the CO₂ into bicarbonate and hydrogen ions. Hgb that is not bound to O₂ combines with the free hydrogen ions, increasing pH. As this binding is occurring, bicarbonate is leaving the RBC in exchange for chloride ions. (For additional information about the relationship between the respiratory and renal components of this buffer system, see monograph titled “Blood Gases.”)

Hgb is included in the complete blood count (CBC) and generally performed with a hematocrit (Hct). These levels parallel each other and are frequently used to evaluate anemia. Polycythemia is a term used in conjunction with conditions resulting from an abnormal increase in Hgb, Hct, and RBC count. Anemia is a term associated with conditions resulting from an abnormal decrease in Hgb, Hct, and RBC count. Results of the Hgb, Hct, and RBC count should be evaluated simultaneously because the same underlying conditions affect this triad of tests similarly. The RBC count multiplied by 3 should approximate the Hgb concentration. The Hct should be within three times the Hgb if the RBC population is normal in size and shape. The Hct plus 6 should approximate the first two figures of the RBC count within 3 (e.g., Hct is 40%; therefore 40 + 6 = 46, and the RBC count should be 4.6 or in the range of 4.3 to 4.9). There are some cultural variations in Hgb and Hct (H&H) values. After the first decade of life, the mean Hgb in African Americans is 0.5 to 1.0 g lower than in whites. Mexican Americans and Asian Americans have higher Hgb and H&H values than whites.
**INDICATIONS:**

- Detect hematologic disorder, neoplasm, or immunologic abnormality
- Determine the presence of hereditary hematologic abnormality
- Evaluate known or suspected anemia and related treatment, in combination with Hct
- Monitor blood loss and response to blood replacement, in combination with Hct
- Monitor the effects of physical or emotional stress on the patient
- Monitor fluid imbalances or their treatment
- Monitor hematologic status during pregnancy, in combination with Hct
- Monitor the progression of non-hematologic disorders, such as chronic obstructive pulmonary disease (COPD), malabsorption syndromes, cancer, and renal disease
- Monitor response to drugs or chemotherapy, and evaluate undesired reactions to drugs that may cause blood dyscrasias
- Provide screening as part of a CBC in a general physical examination, especially upon admission to a health care facility or before surgery

**RESULT:**

**Increased in:**

- Burns (Related to dehydration; total blood volume is decreased but RBC count remains the same)
- Congestive heart failure (When the underlying cause is anemia, the body will respond by increasing production of RBCs; with a responding increase in Hct)
- COPD (Related to chronic hypoxia that stimulates production of RBCs and a corresponding increase in Hgb)
- Dehydration (Total blood volume is decreased but RBC count remains the same)
- Erythrocytosis (Total blood volume remains the same but RBC count is increased)

- Hemoconcentration (Same effect as seen in dehydration)
- High altitudes (Related to hypoxia that stimulates production of RBCs and therefore increases Hgb)
- Polycythemia vera (Abnormal bone marrow response resulting in overproduction of RBCs)

**Decreased in:**

- Anemias (Overall decrease in RBCs and corresponding decrease in Hgb)
- Carcinoma (Anemia is often associated with chronic disease)
- Fluid retention (Dilutional effect of increased blood volume while RBC count remains stable)
- Hemoglobinopathies (Reduced RBC survival with corresponding decrease in Hgb)
- Hemolytic disorders (Reduced RBC survival with corresponding decrease in Hgb)
- Hemorrhage (acute and chronic) (Overall decrease in RBCs and corresponding decrease in Hgb)
- Hodgkin’s disease (Bone marrow failure that results in decreased RBC production)
- Incompatible blood transfusion (Reduced RBC survival with corresponding decrease in Hgb)
- Intravenous overload (Dilutional effect)
- Leukemia (Bone marrow failure that results in decreased RBC production)
- Lymphomas (Bone marrow failure that results in decreased RBC production)
- Nutritional deficit (Anemia related to dietary deficiency in iron, vitamins, folate needed to produce sufficient RBCs; decreased RBC count with corresponding decrease in Hgb)
- Pregnancy (Related to anemia)
- Splenomegaly (Total blood volume remains the same but spleen retains RBCs and Hgb reflects decreased RBC count)
**CRITICAL VALUES:**

Less than 6.0 g/dL
Greater than 18.0 g/dL

Note and immediately report to the health care practitioner any critically increased or decreased values and related symptoms.

- Low Hgb leads to anemia. Anemia can be caused by blood loss, decreased blood cell production, increased blood cell destruction, and hemodilution. Causes of blood loss include menstrual excess or frequency, gastrointestinal bleeding, inflammatory bowel disease, and hematuria. Decreased blood cell production can be caused by folic acid deficiency, vitamin B₁₂ deficiency, iron deficiency, and chronic disease. Increased blood cell destruction can be caused by a hemolytic reaction, chemical reaction, medication reaction, and sickle cell disease. Hemodilution can be caused by congestive heart failure, renal failure, polydipsia, and overhydration. Symptoms of anemia (due to these causes) include anxiety, dyspnea, edema, hypertension, hypotension, hypoxia, jugular venous distention, fatigue, pallor, rales, restlessness, and weakness. Treatment of anemia depends on the cause.

- High Hgb leads to polycythemia. Polycythemia can be caused by dehydration, decreased oxygen levels in the body, and an overproduction of RBCs by the bone marrow. Dehydration from diuretic use, vomiting, diarrhea, excessive sweating, severe burns, or decreased fluid intake decreases the plasma component of whole blood, thereby increasing the ratio of RBCs to plasma and leads to a higher than normal Hgb. Causes of decreased oxygen include smoking, exposure to carbon monoxide, high altitude, and chronic lung disease, which leads to a mild hemoconcentration of blood in the body to carry more oxygen to the body’s tissues. An overproduction of RBCs by the bone marrow leads to polycythemia vera, which is a rare chronic myeloproliferative disorder that leads to a severe hemoconcentration of blood. Severe hemoconcentration can lead to thrombosis (spontaneous blood clotting). Symptoms of hemoconcentration include decreased pulse pressure and volume, loss of skin turgor, dry mucous membranes, headaches, hepatomegaly, low central venous pressure, orthostatic hypotension, pruritis (especially after a hot bath), splenomegaly, tachycardia, thirst, tinnitus, vertigo, and weakness. Treatment of polycythemia depends on the cause. Possible interventions for hemoconcentration due to dehydration include intravenous fluids and discontinuance of diuretics if they are believed to be contributing to critically elevated Hgb. Polycythemia due to decreased oxygen states can be treated by removal of the offending substance, such as smoke or carbon monoxide. Treatment includes oxygen therapy in cases of smoke inhalation, carbon monoxide poisoning, and desaturating chronic lung disease. Symptoms of polycythemic overload crisis include signs of thrombosis, pain and redness in extremities, facial flushing, and irritability. Possible interventions for hemoconcentration due to polycythemia include therapeutic phlebotomy and intravenous fluids.

**INTERFERING FACTORS:**

- Drugs and substances that may cause a decrease in Hgb levels include those that induce hemolysis due to drug sensitivity or enzyme deficiency, such as acetaminophen, aminopyrine, aminosalicylic acid, amphetamine, anticonvulsants,
antimalarials, antipyretics, antipyrine, arsenicals, benzene, busulfan, carbenicillin, cephalothin, chemotherapy drugs, chlorate, chloroquine, chlorothiazide, chlorpromazine, colchicine, corticosteroids, dapsone, dimercaprol, diphenhydramine, dipyrone, glucosulfone, glycerin, gold, hydroflumethiazide, indomethacin, mephenytoin, methyldopa, nalidixic acid, neomycin, niridazole, nitrobenzene, nitrofurantoin, novobiocin, penicillin, phenacemide, phenazopyridine, and phenothiazines; and those that result in anemia, such as miconazole, penicillamine, phenylhydrazine, primaquine, probenecid, pyrazolones, pyrimethamine, quinines, streptomycin, sulfamethizole, sulfamethoxypyridazine, sulfisoxazole, suramin, thioridazine, tolbutamide, trimethadione, and tripelemamine.

- Some drugs may also affect Hgb values by increasing or decreasing the RBC count (see monograph titled “Complete Blood Count, RBC Count”).

- The results of RBC counts may vary depending on the patient’s position: Hgb can decrease when the patient is recumbent as a result of hemodilution and can increase when the patient rises as a result of hemoconcentration.

- Use of the nutraceutical liver extract is strongly contraindicated in iron-storage disorders, such as hemochromatosis, because it is rich in heme (the iron-containing pigment in Hgb).

- A severe copper deficiency may result in decreased Hgb levels.

- Cold agglutinins may falsely increase the mean corpuscular Hgb concentration (MCHC) and decrease the RBC count, affecting Hgb values. This can be corrected by warming the blood or replacing the plasma with warmed saline and repeating the analysis.

- Leaving the tourniquet in place for longer than 60 sec can falsely increase Hgb levels by 2% to 5%.

- Failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.

- Clotted or hemolized specimens must be rejected for analysis.

- Care should be taken in evaluating the Hgb during the first few hours after transfusion or acute blood loss because the value may appear to be normal.

- Abnormalities in the RBC size (macrocytes, microcytes) or shape (spherocytes, sickle cells) may alter Hgb values, as in diseases and conditions including sickle cell anemia, hereditary spherocytosis, and iron deficiency.

- Lipemia will falsely increase the Hgb measurement, also affecting the mean corpuscular volume (MCV) and MCHC. This can be corrected by replacing the plasma with saline, repeating the measurement, and manually correcting the Hgb, MCH, and MCHC using specific mathematical formulas.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- Inform the patient that the test is used to evaluate anemia, polycythemia, and hydration status and to monitor therapy.

- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

- Obtain a history of the patient’s cardiovascular, gastrointestinal, hematopoietic, hepatobiliary, immune, musculoskeletal, and respiratory systems, symptoms, and results of previously performed laboratory
tests and diagnostic and surgical procedures.
Note any recent procedures that can interfere with test results.
Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL lavender-top (EDTA) tube. An EDTA Microtainer sample may be obtained from infants, children, and adults for whom venipuncture may not be feasible. The specimen should be mixed gently by inverting the tube 10 times. The specimen should be analyzed within 6 hr when stored at room temperature or within 24 hr if stored at refrigerated temperature. If it is anticipated the specimen will not be analyzed within 4 to 6 hr, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 6 hr will contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and spherocytes, as well as necrobiotic white blood cells.
Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
**Nutritional considerations:** Nutritional therapy may be indicated for patients with decreased Hgb. Iron deficiency is the most common nutrient deficiency in the United States. Patients at risk (e.g., children, pregnant women and women of childbearing age, low-income populations) should be instructed to include foods that are high in iron in their diet, such as meats (especially liver), eggs, grains, green leafy vegetables, and multivitamins with iron. Iron absorption is affected by numerous factors (see monograph titled “Iron”).
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPH:**
Related tests include biopsy bone marrow, biopsy lymph node, biopsy kidney, blood groups and antibodies, complete blood count, Coomb’s antiglobulin, CT thoracic, erythropoietin, fecal analysis (occult blood), ferritin, gallium scan, haptoglobin, complete blood count hematocrit, hemoglobin electrophoresis, iron/TIBC, lymphangiogram, Meckel’s diverticulum scan, reticulocyte count, and sickle cell screen.
Refer to the Cardiovascular, Gastrointestinal, Hematopoietic, Hepatobiliary, Immune, Musculoskeletal, and Respiratory System tables at the back of the book for related tests by body system.

*Conventional units.

Note: Platelet counts decrease with age.

DESCRIPTION: Platelets are non-nucleated, cytoplasmic, round or oval disks formed by budding off of large, multinucleated cells (megakaryocytes). Platelets have an essential function in coagulation, hemostasis, and blood thrombus formation. Thrombocytosis is an increase in platelet count. In reactive thrombocytosis, the increase is transient and short-lived, and it usually does not pose a health risk. One exception may be reactive thrombocytosis occurring after coronary bypass surgery. This circumstance has been identified as an important risk factor for postoperative infarction and thrombosis. The term thrombocytopenia is used to describe platelet increases associated with chronic myeloproliferative disorders; thrombocytopenia is used to describe platelet counts of less than $140 \times 10^3/microL$.

Decreased platelet counts occur whenever the body’s need for platelets exceeds the rate of platelet production; this circumstance will arise if production rate decreases or platelet loss increases. The severity of bleeding is related to platelet count as well as platelet function. Platelet counts can be within normal limits, but the patient may exhibit signs of internal bleeding; this circumstance usually indicates an anomaly in platelet function. Abnormal scatterplot findings by automated cell counters may indicate the need to review a smear of peripheral blood for platelet estimate. Abnormally large or giant platelets may result in underestimation of automated counts by 30% to 50%. A large discrepancy between the automated count and the estimate requires that a manual count be performed.
The significance of platelet sizing is becoming more widely known, as modern cell counters are capable of reporting platelet indexes that are analogous to red blood cell (RBC) indices. Platelet size, reflected by mean platelet volume (MPV), and cellular age are inversely related; that is, younger platelets tend to be larger. An increase in MPV indicates an increase in platelet turnover. Therefore, in a normal patient the platelet count and MPV have an inverse relationship. Abnormal platelet size may also indicate the presence of a disorder. MPV and platelet distribution width (PDW) are both increased in idiopathic thrombocytopenic purpura. MPV is also increased in May-Hegglin anomaly, Bernard-Soulier syndrome, myeloproliferative disorders, hyperthyroidism, and pre-eclampsia. MPV is decreased in Wiskott-Aldrich syndrome, septic thrombocytopenia, and hypersplenism.

Medications like clopidogrel (Plavix®) and aspirin have antiplatelet effects and are prescribed to prevent heart attack, stroke, and blockage of coronary stents. Studies have confirmed that up to 30% of patients receiving these medications may be nonresponsive. Tests to assess platelet function can provide information that confirms platelet response. Platelet response testing helps ensure alternative or additional platelet therapy is instituted, if necessary. The test results can also be used preoperatively to determine whether antiplatelet medications have been sufficiently cleared from the patient’s circulation such that surgery can safely be performed without risk of excessive bleeding.

**INDICATIONS:**
- Confirm an elevated platelet count (thrombocytosis), which can cause increased clotting
- Confirm a low platelet count (thrombocytopenia), which can be associated with bleeding
- Identify the possible cause of abnormal bleeding, such as epistaxis, hematoma, gingival bleeding, hematuria, and menorrhagia
- Provide screening as part of a complete blood count (CBC) in a general physical examination, especially upon admission to a health care facility or before surgery

**RESULT:**

**Increased in:**
**Conditions that involve inflammation activate and increase the number of circulating platelets:**
- Acute infections
- After exercise (transient)
- Anemias (posthemorrhagic, hemolytic, iron-deficiency) *(Bone marrow response to anemia; platelet formation is unaffected by iron deficiency)*
- Chronic heart disease
- Cirrhosis
- Essential thrombocythemia
- Leukemias (chronic)
- Malignancies (carcinoma, Hodgkin’s, lymphomas)
- Pancreatitis (chronic)
- Polycythemia vera *(Hyperplastic bone marrow response in all cell lines)*
- Rebound recovery from thrombocytopenia *(Initial response)*
- Rheumatic fever (acute)
- Rheumatoid arthritis
- Splenectomy (2 mo postprocedure) *(Normal function of the spleen is to cull aging cells from the blood; without the spleen the count increases)*
- Surgery (2 wk postprocedure)
• Trauma
• Tuberculosis
• Ulcerative colitis

**Decreased in:**

**Decreased in (as a result of Megakaryocytic Hypoproliferation):**
- Alcohol toxicity
- Aplastic anemia
- Congenital states (Fanconi’s syndrome, May-Hegglin anomaly, Bernard-Soulier syndrome, Wiskott-Aldrich syndrome, Gaucher’s disease, Chédiak-Higashi syndrome)
- Drug toxicity
- Prolonged hypoxia

**Decreased in (as a result of ineffective thrombopoiesis):**
- Ethanol abuse without malnutrition
- Iron-deficiency anemia
- Megaloblastic anemia (B₁₂/folate deficiency)
- Paroxysmal nocturnal hemoglobinuria
- Thrombopoietin deficiency
- Viral infection

**Decreased in (as a result of bone marrow replacement):**
- Lymphoma
- Granulomatous infections
- Metastatic carcinoma
- Myelofibrosis

**Increased in:**

**Increased destruction in (as a result of increased loss/consumption):**
- Contact with foreign surfaces (dialysis membranes, artificial organs, grafts, prosthetic devices)
- Disseminated intravascular coagulation
- Extensive transfusion
- Severe hemorrhage
- Thrombotic thrombocytopenic purpura
- Uremia

**Increased destruction in (as a result of immune reaction):**
- Antibody/human leukocyte antigen reactions
- Hemolytic disease of the newborn (target is platelets instead of RBCs)
- Idiopathic thrombocytopenic purpura
- Refractory reaction to platelet transfusion

**Increased destruction in (as a result of immune reaction secondary to infection):**
- Bacterial infections
- Burns
- Congenital infections (cytomegalovirus, herpes, syphilis, toxoplasmosis)
- Histoplasmosis
- Malaria
- Rocky Mountain spotted fever

**Increased destruction in (as a result of other causes):**
- Radiation
- Splenomegaly caused by liver disease

**CRITICAL VALUES:**
- Less than 50,000 × 10³/microL (or 50 × 10³/mm³ or 50,000/mm³)
- Greater than 1,000 × 10³/microL (or 1,000,000/mm³)

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms. Possible interventions for decreased platelet count may include transfusion of platelets.

**INTERFERING FACTORS:**
- Drugs that may decrease platelet counts include acetohexamide, acetophenazine, amphotericin B, antazoline, anticonvulsants, antimony compounds, apronalide, arsenicals, azathioprine, barbiturates, benzene, busulfan, butaperazine, chlordane,
chlorophenothane, chlortetracycline, 
dactinomycin, dextromethorphan, 
diethylstilbestrol, ethinamate, 
etoxozolamide, fluoridine, 
hexachlorobenzene, hydantoin 
derivatives, hydroflumethiazide, 
hydroxychloroquine, iproniazid, 
mechlorethamine, mefenamic 
acid, mepazine, miconazole, 
methotrexate, nitrofurantoin, 
novobiocin, nystatin, phenolph-
thalein, phenothiazine, 
pipamazine, plicamycin, 
procainamide, pyrazolones, 
streptomycin, sulfonamides, tetracycline, 
thiabendazole, thiouracil, 
tolazamide, tolazoline, 
tolbutamide, trifluoperazine, and 
urethane.

• Drugs that may increase platelet 
counts include glucocorticoids.
• X-ray therapy may also decrease 
platelet counts.
• The results of blood counts may 
vary depending on the patient’s 
position. Platelet counts can 
decrease when the patient is 
recumbent, as a result of hemodi-
lution, and can increase when the 
patient rises, as a result of hemo-
concentration.
• Platelet counts normally increase 
under a variety of stressors, such 
as high altitudes or strenuous 
exercise.
• Platelet counts are normally 
decreased before menstruation and 
during pregnancy.
• Leaving the tourniquet in place for 
longer than 60 sec can affect the 
results.
• Traumatic venipunctures may lead 
to erroneous results as a result of 
activation of the coagulation 
sequence.
• Failure to fill the tube sufficiently 
(i.e., tube less than three-quarters 
full) may yield inadequate sample 
volume for automated analyzers 
and may be a reason for specimen 
rejection.

• Hemolysis or clotted specimens 
are reasons for rejection.
• CBC should be carefully evaluated 
after transfusion or acute blood 
loss because the value may appear 
to be normal.
• A white blood cell count greater 
than $100 \times 10^3$/mm$^3$, severe RBC fragmentation, and 
extraneous particles in the fluid 
used to dilute the sample can 
alter test results.
Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. The specimen should be mixed gently by inverting the tube 10 times. The specimen should be analyzed within 6 hr when stored at room temperature or within 24 hr if stored at refrigerated temperature. If it is anticipated the specimen will not be analyzed within 4 to 6 hr, two blood smears should be made immediately after the venipuncture and submitted with the blood sample.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to report bleeding from any areas of the skin or mucous membranes.
- Inform the patient with a decreased platelet count of the importance of taking precautions against bruising and bleeding, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of acetylsalicylic acid and similar products, and avoidance of intramuscular injections.
- Inform the patient of the importance of periodic laboratory testing if he or she is taking an anticoagulant.

**Nutritional considerations:** Instruct patients to consume a variety of foods within the basic food groups, maintain a healthy weight, be physically active, limit salt intake, limit alcohol intake, and avoid the use of tobacco.

- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include antiarrhythmic drugs (quinidine), biopsy bone marrow, bleeding time, blood groups and antibodies, clot retraction, coagulation factors, complete blood count, CT angiography, CT brain, FDP, fibrinogen, PTT, platelet antibodies, PT/INR, complete blood count RBC morphology and inclusions, US pelvis, and complete blood count WBC count and differential.
- Refer to the Hematopoietic and Immune System tables at the back of the book for related tests by body system.

DESCRIPTION: A component of the complete blood count (CBC), the red blood cell (RBC) count determines the number of RBCs per cubic millimeters (expressed as the number of RBCs per liter of blood according to the international system of units [SI]). Because RBCs contain hemoglobin (Hgb), which is responsible for the transport and exchange of oxygen, the number of circulating RBCs is important. Although the life span of the normal RBC is 120 days, other factors besides cell age and decreased production can cause decreased values; examples are abnormal destruction due to intravascular trauma caused by atherosclerosis or to an enlarged spleen caused by leukemia. The main sites of RBC production in healthy adults include the bone marrow of the vertebrae, pelvis, ribs, sternum, skull, and proximal ends of the femur and humerus. The main sites of RBC destruction are the spleen and liver. Erythropoietin, a hormone produced by the kidneys, regulates RBC production. Normal RBC development and function are also dependent on adequate levels of vitamin B₁₂, folate, and iron. A deficiency in vitamin E (α-tocopherol), which is needed to protect the RBC membrane from oxidizers, can result in increased cellular destruction. Polycythemia is a term used in conjunction with conditions resulting from an abnormal increase in Hgb, hematocrit (Hct), and RBC count. Anemia is a term associated with conditions resulting from an abnormal decrease in Hgb, Hct, and RBC count. Results of the Hgb, Hct, and RBC count should be evaluated simultaneously because the same underlying
conditions affect this triad of tests similarly. The RBC count multiplied by 3 should approximate the Hgb concentration. The Hct should be within three times the Hgb if the RBC population is normal in size and shape. The Hct plus 6 should approximate the first two figures of the RBC count within 3 (e.g., Hct is 40%; therefore 40 + 6 = 46, and the RBC count should be 4.6 or in the range 4.3 to 4.9). (See monographs titled “Complete Blood Count, Hematocrit,” “Complete Blood Count, Hemoglobin,” and “Complete Blood Count, RBC Indices.”)

**INDICATIONS:**
- Detect a hematological disorder involving RBC destruction (e.g., hemolytic anemia)
- Determine the presence of hereditary hematological abnormality
- Monitor the effects of acute or chronic blood loss
- Monitor the effects of physical or emotional stress on the patient
- Monitor patients with disorders associated with elevated erythrocyte counts (e.g., polycythemia vera, chronic obstructive pulmonary disease [COPD])
- Monitor the progression of nonhematological disorders associated with elevated erythrocyte counts, such as COPD, liver disease, hypothyroidism, adrenal dysfunction, bone marrow failure, malabsorption syndromes, cancer, and renal disease
- Monitor the response to drugs or chemotherapy and evaluate undesired reactions to drugs that may cause blood dyscrasias
- Provide screening as part of a CBC in a general physical examination, especially upon admission to a health care facility or before surgery

**RESULT:**

**Increased in:**
- Anxiety or stress (Related to physiological response)
- Bone marrow failure (Initial response is stimulation of RBC production)
- COPD with hypoxia and secondary polycythemia (Related to chronic hypoxia that stimulates production of RBCs and a corresponding increase in RBCs)
- Dehydration with hemocentration (Total blood volume decreases but RBC count remains the same)
- Erythremic erythrocytosis (Total blood volume remains the same but RBC count is increased)
- High altitude (Related to hypoxia that stimulates production of RBCs)
- Polycythemia vera (Abnormal bone marrow response resulting in overproduction of RBCs)

**Decreased in:**
- Chemotherapy (Reduced RBC survival)
- Chronic inflammatory diseases (Anemia is often associated with chronic disease)
- Hemoglobinopathy (Reduced RBC survival)
- Hemolytic anemia (Reduced RBC survival)
- Hemorrhage (Overall decrease in RBC count)
- Hodgkin’s disease (Bone marrow failure that results in decreased RBC production)
- Leukemia (Bone marrow failure that results in decreased RBC production)
- Multiple myeloma (Bone marrow failure that results in decreased RBC production)
- Nutritional deficit (Deficiency of iron or vitamins required for RBC production and/or maturation)
- Overhydration (Blood volume increases but RBC count remains the same)
• Pregnancy (Related to anemia; normal dilutional effect)
• Renal disease (Related to decreased production of erythropoietin)
• Subacute endocarditis

**CRITICAL VALUES:**
The presence of abnormal cells, other morphological characteristics, or cellular inclusions may signify a potentially life-threatening or serious health condition and should be investigated. Examples are the presence of sickle cells, moderate numbers of spherocytes, marked schistocytosis, oval macrocytes, basophilic stippling, nucleated RBCs (if the patient is not an infant), or malarial organisms.

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms.

• Low RBC count leads to anemia. Anemia can be caused by blood loss, decreased blood cell production, increased blood cell destruction, or hemodilution. Causes of blood loss include menstrual excess or frequency, gastrointestinal bleeding, inflammatory bowel disease, or hematuria. Decreased blood cell production can be caused by folic acid deficiency, vitamin B₁₂ deficiency, iron deficiency, or chronic disease. Increased blood cell destruction can be caused by a hemolytic reaction, chemical reaction, medication reaction, or sickle cell disease. Hemodilution can be caused by congestive heart failure, renal failure, polydipsia, or overhydration. Symptoms of anemia (due to these causes) include anxiety, dyspnea, edema, hypertension, hypotension, hypoxia, jugular venous distention, fatigue, pallor, rales, restlessness, and weakness. Treatment of anemia depends on the cause.

• High RBC count leads to polycythemia. Polycythemia can be caused by dehydration, decreased oxygen levels in the body, and an overproduction of RBCs by the bone marrow. Dehydration by diuretic use, vomiting, diarrhea, excessive sweating, severe burns, or decreased fluid intake decreases the plasma component of whole blood, thereby increasing the ratio of RBCs to plasma, and leads to a higher than normal Hct. Causes of decreased oxygen include smoking, exposure to carbon monoxide, high altitude, and chronic lung disease, which leads to a mild hemococoncentration of blood in the body to carry more oxygen to the body’s tissues. An overproduction of RBCs by the bone marrow leads to polycythemia vera, which is a rare chronic myeloproliferative disorder that leads to a severe hemococoncentration of blood. Severe hemococoncentration can lead to thrombosis (spontaneous blood clotting).

Symptoms of hemococoncentration include decreased pulse pressure and volume, loss of skin turgor, dry mucous membranes, headaches, hepatomegaly, low central venous pressure, orthostatic hypotension, pruritis (especially after a hot bath), splenomegaly, tachycardia, thirst, tinnitus, vertigo, and weakness. Treatment of polycythemia depends on the cause. Possible interventions for hemococoncentration due to dehydration include intravenous fluids and discontinuance of diuretics if they are believed to be contributing to critically elevated Hct. Polycythemia due to decreased oxygen states can be treated by removal of the offending substance, such as smoke or carbon monoxide. Treatment includes oxygen therapy in cases of smoke inhalation, carbon monoxide poisoning, and desaturating chronic lung disease. Symptoms of polycythemic overload crisis include signs of thrombosis, pain and redness in
extremities, facial flushing, and irritability. Possible interventions for hemoconcentration due to polycythemia include therapeutic phlebotomy and intravenous fluids.

**INTERFERING FACTORS:**

- Drugs and substances that may decrease RBC count by causing hemolysis resulting from drug sensitivity or enzyme deficiency include acetaminophen, aminopyrine, aminosalicylic acid, amphetamine, anticonvulsants, antipyrine, arsenicals, benzene, busulfan, carbenicillin, cephalothin, chemotherapy drugs, chlorate, chloroquine, chlorothiazide, chlorpromazine, colchicine, diphenhydramine, dipyrone, glucosulfone, gold, hydroflumethiazide, indomethacin, mefenoxamine, nalidixic acid, neomycin, nitrofurantoin, penicillin, phenacemide, phenazopyridine, and phenothiazine.

- Drugs that may decrease RBC count by causing anemia include miconazole, penicillamine, phenylhydrazine, primaquine, probenecid, pyrazolones, pyrimethamine, quinines, streptomycin, sulfamethizole, sulfamethoxypyridazine, sulfisoxazole, suramin, thioridazine, tolbutamide, trimethadione, and tripentelamine.

- Drugs that may decrease RBC count by causing bone marrow suppression include amphotericin B, floxuridine, and phenylbutazone.

- Drugs and vitamins that may increase the RBC count include glucocorticosteroids, pilocarpine, and vitamin B₁₂.

- Use of the neutraceutical liver extract is strongly contraindicated in patients with iron-storage disorders such as hemochromatosis because it is rich in heme (the iron-containing pigment in Hgb).

RBCs may lead to false decreases in RBC count.

- Cold agglutinins may falsely increase the mean corpuscular volume (MCV) and decrease the RBC count. This can be corrected by warming the blood or diluting the sample with warmed saline and repeating the analysis.

- Excessive exercise, anxiety, pain, and dehydration may cause false elevations in RBC count.

- A grossly elevated white blood cell (WBC) count (greater than 500 × 10⁹/mm³) will cause a falsely elevated RBC count. This can be corrected by diluting the sample with saline to obtain an accurate WBC count and then correcting the RBC mathematically.

- Care should be taken in evaluating the CBC after transfusion.

- RBC counts can vary depending on the patient’s position, decreasing when the patient is recumbent as a result of hemodilution and increasing when the patient rises as a result of hemoconcentration.

- Venous stasis can falsely elevate RBC counts; therefore, the tourniquet should not be left on the arm for longer than 60 sec.

- Failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.

- Hemolyzed or clotted specimens must be rejected for analysis.

---

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate anemia and disorders affecting the number of circulating RBCs.
Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient’s cardiovascular, gastrointestinal, genitourinary, hematopoietic, hepatobiliary, immune, musculoskeletal, and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Note any recent procedures that can interfere with test results.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient.

Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. An EDTA Microtainer sample may be obtained from infants, children, and adults for whom venipuncture may not be feasible. The specimen should be mixed gently by inverting the tube 10 times. The specimen should be analyzed within 6 hr when stored at room temperature or within 24 hr if stored at refrigerated temperature. If it is anticipated the specimen will not be analyzed within 4 to 6 hr, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 6 hr will contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and spherocytes, as well as necrobiotic WBCs.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

*Nutritional considerations:* Nutritional therapy may be indicated for patients with decreased RBC count. Iron deficiency is the most common nutrient deficiency in the United States. Patients at risk (e.g., children, pregnant women and women of childbearing age, low-income populations) should be instructed to include foods that are high in iron in their diet, such as meats (especially liver), eggs, grains, green leafy vegetables, and multivitamins with iron. Iron absorption is affected by numerous factors (see monograph titled “Iron”).

*Nutritional considerations:* Patients at risk for vitamin B$_{12}$ or folate deficiency include those with the following conditions: malnourishment (inadequate intake), pregnancy (increased need), infancy, malabsorption syndromes (inadequate absorption/increased metabolic rate), infections, cancer, hyperthyroidism, serious burns, excessive blood loss, and gastrointestinal damage. These patients should be instructed, as appropriate, to ingest food sources rich in vitamin B$_{12}$, such as meats, milk, cheese, eggs, and fortified soy milk products. Sources of folate are meats (especially liver), kidney beans, beets, vegetables in the cabbage family, oranges, cantaloupe, and green leafy vegetables such as spinach, asparagus, and broccoli.

*Nutritional considerations:* A diet deficient in vitamin E puts the patient at risk for increased RBC destruction, which...
could lead to anemia. Nutritional therapy may be indicated for these patients. Vitamin E is found in many of the previously mentioned foods, as well as in vegetable oils and wheat germ. Supplemental vitamin E may also be taken, but the danger of toxicity should be explained to the patient. Very large supplemental doses, in excess of 600 mg of vitamin E over a period of 1 yr, may result in excess bleeding. Vitamin E is heat stable but is very negatively affected by light.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include biopsy bone marrow, biopsy kidney, blood groups and antibodies, complete blood count, complete blood count hematocrit, complete blood count hemoglobin, complete blood count, RBC morphology and inclusions, Coomb’s antiglobulin, erythropoietin, fecal analysis, ferritin, folate, gallium scan, haptoglobin, iron/TIBC, lymphangiogram, Meckel’s diverticulum scan, reticulocyte count, and vitamin B₁₂.
- Refer to the Cardiovascular, Gastrointestinal, Genitourinary, Hematopoietic, Hepatobiliary, Immune, Musculoskeletal, and Respiratory System tables at the back of the book for related tests by body system.

**SYNONYM/ACRONYM:**
Mean corpuscular hemoglobin (MCH), mean corpuscular volume (MCV), mean corpuscular hemoglobin concentration (MCHC), red blood cell distribution width (RDW).

**SPECIMEN:** Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

**REFERENCE VALUE:** (Method: Automated, computerized, multichannel analyzers that sort and size cells on the basis of changes in either electrical impedance or light pulses as the cells pass in front of a laser)

*MCV = mean corpuscular volume; MCH = mean corpuscular hemoglobin; MCHC = mean corpuscular hemoglobin concentration; RDW = red blood cell distribution width.
**DESCRIPTION:** Red blood cell (RBC) indices provide information about the mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), and RBC distribution width (RDW). The hematocrit, RBC count, and total hemoglobin tests are used to determine the RBC indices. MCV is determined by dividing the hematocrit by the total RBC count and is helpful in classifying anemias. MCH is determined by dividing the total hemoglobin concentration by the RBC count. MCHC is determined by dividing total hemoglobin by hematocrit. Hemoglobin content is indicated as normochromic, hypochromic, and hyperchromic. The RDW is a measurement of cell size distribution over the entire RBC population measured. It can indicate anisocytosis, or excessive variations in cell size. Cell size is indicated as normocytic, microcytic, and macrocytic. (See monographs titled “Complete Blood Count, Hemoglobin,” “Complete Blood Count, Hematocrit,” “Complete Blood Count, RBC Count,” and “Complete Blood Count, RBC Morphology and Inclusions.”)

**INDICATIONS:**
- Assist in the diagnosis of anemia
- Detect a hematological disorder, neoplasm, or immunological abnormality
- Determine the presence of a hereditary hematological abnormality
- Monitor the effects of physical or emotional stress
- Monitor the progression of nonhematological disorders such as chronic obstructive pulmonary disease, malabsorption syndromes, cancer, and renal disease

**RESULT:**

**Increased in:**
- **MCV** Increased in:
  - Alcoholism (*Vitamin deficiency related to malnutrition*)
  - Antimetabolite therapy (*The therapy inhibits vitamin B₁₂ and folate*)
  - Liver disease (*Complex effect on RBCs that includes malnutrition, alterations in RBC shape and size, effects of chronic disease*)
  - Pernicious anemia (*Vitamin B₁₂/folate anemia*)
- **MCH** Increased in:
  - Macrocytic anemias (*Related to increased hemoglobin or cell size*)
- **MCHC** Increased in:
  - Spherocytosis (*Artifact in measurement caused by abnormal cell shape*)
- **RDW** Increased in:
  - Anemias with heterogeneous cell size as a result of hemoglobinopathy, hemolytic anemia, anemia following acute blood loss, iron-deficiency anemia, vitamin- and folate-deficiency anemia (*Related to a mixture of cell sizes as the bone marrow responds to the anemia and/or to a mixture of cell shapes due to cell fragmentation as a result of the disease*)

**Decreased in:**
- **MCV** Decreased in:
  - Iron-deficiency anemia (*Low hemoglobin*)
  - Thalassemias (*Low hemoglobin*)

Access additional resources at davisplus.fadavis.com
MCH Decreased in:
- Hypochromic anemias (Low hemoglobin)
- Microcytic anemias (Low hemoglobin)

MCHC Decreased in:
- Iron-deficiency anemia (The amount of hemoglobin in the RBC is small relative to RBC size)

RDW Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs and substances that may decrease the MCHC include styrene (occupational exposure).
- Drugs that may decrease the MCV include nitrofurantoin.
- Drugs that may increase the MCV include colchicine, pentamidine, pyrimethamine, and triamterene.
- Drugs that may increase the MCH and MCHC include oral contraceptives (long-term use).
- Diseases that cause agglutination of RBCs will alter test results.
- Cold agglutinins may falsely increase the MCV and decrease the RBC count. This can be corrected by warming the blood or diluting the sample with warmed saline and then correcting the RBC count mathematically.
- RBC counts can vary depending on the patient’s position, decreasing when the patient is recumbent as a result of hemodilution and increasing when the patient rises as a result of hemoconcentration.
- Care should be taken in evaluating the CBC after transfusion.
- Venous stasis can falsely elevate RBC counts; therefore, the tourniquet should not be left on the arm for longer than 60 sec.
- Failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.
- Hemolyzed or clotted specimens should be rejected.
- Lipemia and elevated white blood cell (WBC) count (greater than 50 \( \text{WBC} \times 10^3/\text{mm}^3 \) or 50,000/mm\(^3\)) will falsely increase the hemoglobin measurement, also affecting the MCV and MCH.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is primarily used to assess RBC shape and size.
- Obtain a history of the patient’s complaints, including a list of known allergens especially allergies or sensitivities to latex.
- Obtain a history of the patient’s gastrointestinal, hematopoietic, immune, and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement. Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. An EDTA Microtainer sample may be obtained from infants, children, and adults for whom venipuncture may not be feasible. The specimen should be mixed gently by inverting the tube 10 times. It is stable when stored for up to 6 hr at room temperature or 24 hr if stored refrigerated. In addition, if it is anticipated that the specimen will not be analyzed within 4 to 6 hr, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 6 hr will contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and spherocytes, as well as necrobiotic WBCs.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage. Promptly transport the specimen to the laboratory for processing and analysis.

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient. Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

Related tests include biopsy bone marrow, complete blood count, complete blood count hematocrit, complete blood count hemoglobin, complete blood count RBC count, complete blood count RBC morphology and inclusions, complete blood count WBC count and differential, erythropoietin, ferritin, folate, Hgb electrophoresis, iron/TIBC, lead, reticulocyte count, sickle cell screen, and vitamin B12.

Refer to the Gastrointestinal, Hematopoietic, Immune, and Respiratory System tables at the back of the book for related tests by body system.

**Complete Blood Count, RBC Morphology and Inclusions**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Whole blood from one full lavender-top (EDTA) tube or Wright’s-stained, thin-film peripheral blood smear. The laboratory should be consulted as to the necessity of thick-film smears for the evaluation of malarial inclusions.

**REFERENCE VALUE:** (Method: Microscopic, manual review of stained blood smear)

</table>
DESCRIPTION: The decision to manually review a peripheral blood smear for abnormalities in red blood cell (RBC) shape or size is made based on criteria established by the reporting laboratory. Cues in the results of the complete blood count (CBC) will point to specific abnormalities that can be confirmed visually by microscopic review of the sample on a stained blood smear.

INDICATIONS:
- Assist in the diagnosis of anemia
- Detect a hematological disorder, neoplasm, or immunological abnormality
- Determine the presence of a hereditary hematological abnormality
- Monitor the effects of physical or emotional stress on the patient
- Monitor the progression of non-hematological disorders, such as chronic obstructive pulmonary disease, malabsorption syndromes, cancer, and renal disease
- Monitor the response to drugs or chemotherapy, and evaluate undesired reactions to drugs that may cause blood dyscrasias
- Provide screening as part of a CBC in a general physical examination, especially upon admission to a health care facility or before surgery

RESULT:
Red Blood Cell Size

*Increased in:*
- Alcoholism
- Aplastic anemia
- Chemotherapy
- Chronic hemolytic anemia
- Grossly elevated glucose (hyperosmotic)
- Hemolytic disease of the newborn
- Hypothyroidism
- Leukemia
- Lymphoma
- Metastatic carcinoma
- Myelofibrosis
- Myeloma
- Refractory anemia
- Sideroblastic anemia
- Vitamin B₁₂/folate deficiency

*Decreased in:*
- Hemoglobin C disease
- Hemolytic anemias
- Hereditary spherocytosis
- Inflammation
- Iron-deficiency anemia
- Thalassemias

**Red Blood Cell Shape**

Variations in cell shape are the result of hereditary conditions such as elliptocytosis, sickle cell anemia, spherocytosis, thalassemias, or hemoglobinopathies (e.g., hemoglobin C disease). Irregularities in cell shape can also result from acquired conditions, such as physical/mechanical cellular trauma, exposure to chemicals, or reactions to medications.

- Acquired spherocytosis can result from Heinz body hemolytic anemia, microangiopathic hemolytic anemia, secondary isoimmunohemolytic anemia, and transfusion of old banked blood.
- Acanthocytes are associated with acquired conditions such as alcoholic cirrhosis with hemolytic anemia, disorders of lipid metabolism, hepatitis of newborns, malabsorptive diseases, metastatic liver disease, the post-splenectomy period, and pyruvate kinase deficiency.
- Burr cells are commonly seen in acquired renal insufficiency, burns, cardiac valve disease, disseminated intravascular coagulation (DIC), hypertension, intravenous fibrin deposition, metastatic malignancy, normal neonatal period, and uremia.
• Codocytes are seen in hemoglobinopathies, iron-deficiency anemia, obstructive liver disease, and the postsplenectomy period.

• Dacryocytes are most commonly associated with metastases to the bone marrow, myelofibrosis, myeloid metaplasia, pernicious anemia, and tuberculosis.

• Schistocytes are seen in burns, cardiac valve disease, DIC, glomerulonephritis, hemolytic anemia, microangiopathic hemolytic anemia, renal graft rejection, thrombotic thrombocytopenic purpura, uremia, and vasculitis.

**Red Blood Cell Hemoglobin Content**

RBCs with a normal hemoglobin (Hgb) level have a clear central pallor and are referred to as normochromic.

- Cells with low Hgb and lacking in central pallor are referred to as hypochromic. Hypochromia is associated with iron-deficiency anemia, thalassemias, and sideroblastic anemia.

- Cells with excessive Hgb levels are referred to as hyperchromic, even though they technically lack a central pallor. Hyperchromia is usually associated with an elevated mean corpuscular Hgb concentration as well as hemolytic anemias.

- Cells referred to as polychromic are young erythrocytes that still contain ribonucleic acid (RNA). The RNA is picked up by the Wright’s stain. Polychromasia is indicative of premature release of RBCs from bone marrow secondary to increased erythropoietin stimulation.

**Red Blood Cell Inclusions**

* RBC inclusions can result from certain types of anemia, abnormal Hgb precipitation, or parasitic infection.

- Cabot rings may be seen in megaloblastic and other anemias, lead poisoning, and conditions in which RBCs are destroyed before they are released from bone marrow.

- Basophilic stippling is seen whenever there is altered Hgb synthesis, as in thalassemias, megaloblastic anemias, alcoholism, and lead or arsenic intoxication.

- Howell-Jolly bodies are seen in sickle cell anemia, other hemolytic anemias, megaloblastic anemia, congenital absence of the spleen, and the postsplenectomy period.

- Pappenheimer bodies may be seen in cases of sideroblastic anemia, thalassemias, refractory anemia, dyserythropoietic anemias, hemosiderosis, and hemochromatosis.

- Heinz bodies are most often seen in the blood of patients who have ingested drugs known to induce the formation of these inclusion bodies. They are also seen in patients with hereditary glucose-6-phosphate dehydrogenase (G6PD) deficiency.

- Hgb C crystals can often be identified in stained peripheral smears of patients with hereditary hemoglobin C disease.

- Parasites such as *Plasmodium* (transmitted by mosquitoes and causing malaria) and *Babesia* (transmitted by ticks), known to invade human RBCs, can be visualized with Wright’s stain and other special stains of the peripheral blood.

**CRITICAL VALUES:** The presence of sickle cells or parasitic inclusions should be brought to the immediate attention of the requesting health care provider (HCP).

**INTERFERING FACTORS:**

- Drugs and substances that may increase Heinz body formation as an initial precursor to significant hemolysis include acetaminol,
acetylsalicylic acid, aminopyrine, antimalarials, antipyretics, furadalone, furazolidone, methylene blue, naphthalene, and nitrofurans.

- Care should be taken in evaluating the CBC after transfusion.
- Leaving the tourniquet in place for longer than 60 sec can falsely affect the results.
- Morphology can be evaluated to some extent via indices; therefore, failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.
- Hemolyzed or clotted specimens should be rejected.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess red blood cell appearance.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular, gastrointestinal, hematopoietic, hepatobiliary, immune, musculoskeletal, and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. An EDTA Microtainer sample may be obtained from infants, children, and adults for whom venipuncture may not be feasible. The specimen should be mixed gently by inverting the tube 10 times. The specimen should be analyzed within 6 hr when stored at room temperature or within 24 hr if stored at refrigerated temperature. If it is anticipated the specimen will not be analyzed within 4 to 6 hr, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 6 hr will contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and spherocytes, as well as necrobiotic white blood cells.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Nutritional considerations: Instruct patients to consume a variety of foods Access additional resources at davisplus.fadavis.com
within the basic food groups, maintain a healthy weight, be physically active, limit salt intake, limit alcohol intake, and avoid the use of tobacco.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include complete blood count, d-aminolevulinic acid, biopsy bone marrow, erythropoietin, ferritin, G6PD, complete blood count hemoglobin, hemoglobin electrophoresis, iron/TIBC, lead, complete blood count platelet count, complete blood count RBC count, complete blood count RBC indices, reticulocyte count, and complete blood count WBC count with differential.
- Refer to the Cardiovascular, Gastrointestinal, Hematopoietic, Hepatobiliary, Immune, Musculoskeletal, and Respiratory System tables at the back of the book for related tests by body system.

---

**Complete Blood Count, WBC Count and Differential**

**SYNONYM/ACRONYM:** WBC with diff, leukocyte count, white cell count.

**SPECIMEN:** Whole blood from one full lavender-top (EDTA) tube.

**REFERENCE VALUE:** (Method: Automated, computerized, multichannel analyzers that sort and size cells on the basis of changes in either electrical impedance or light pulses as the cells pass in front of a laser. Many of these analyzers are capable of determining a five-part WBC differential.) The WBC count and differential enumerates and identifies granulocytes, lymphocytes, monocytes, eosinophils, and basophils.

*SI Units (Conventional Units × 1 × 10^9/L or WBC × 1000/mm^3)
DESCRIPTION: White blood cells (WBCs) constitute the body’s primary defense system against foreign organisms, tissues, and other substances. The life span of a normal WBC is 13 to 20 days. Old WBCs are destroyed by the lymphatic system and excreted in the feces. Reference values for WBC counts vary significantly with age. WBC counts vary diurnally, with counts being lowest in the morning and highest in the late afternoon. Other variables such as stress and high levels of activity or physical exercise can trigger transient increases of 2000 to 5000 mm$^3$. The main WBC types are neutrophils (band and segmented neutrophils), eosinophils, basophils, monocytes, and lymphocytes. WBCs are produced in the bone marrow. B cell lymphocytes remain in the bone marrow to mature. T cell lymphocytes migrate to and mature in the thymus. The WBC count can be performed alone with the differential cell count or as part of the complete blood count (CBC). The WBC differential can be performed by an automated instrument or manually on a slide prepared from a stained peripheral blood sample. Automated instruments provide excellent, reliable information but the accuracy of the WBC count can be affected by the presence of circulating nucleated red blood cells, clumped platelets, fibrin strands, cold agglutinins, cryoglubulins, intracellular parasitic organisms, or other significant blood cell inclusions and may not be identified in the interpretation of an automated blood count. The decision to report a manual or automated differential is based on specific criteria established by the laboratory. The criteria are designed to identify findings that warrant further investigation or confirmation by manual review. An increased WBC count is termed leukocytosis, and a decreased WBC count is termed leukopenia. A total WBC count indicates the degree of response to a pathological process, but a more complete evaluation for specific diagnoses for any one disorder is provided by the differential count. The WBCs in the count and differential are reported as an absolute value and as a percentage. The relative percentages of cell types are arrived at by basing the enumeration of each cell type on a 100-cell count. The absolute value is obtained by multiplying the relative percentage value of each cell type by the total WBC count. For example, on a CBC report, with a total WBC of 9 × 10$^9$ and WBC differential with 92% segmented neutrophils, 1% band neutrophils, 5% lymphocytes, and 1% monocytes the absolute values are calculated as follows: 92/100 × 9 = 8.3 segs, 1/100 × 9 = 0.1 bands, 5/100 × 9 = 0.45 lymphs.
1/100 × 9 = 0.1 monos for a total of 9.0 WBC count.

Acute leukocytosis is initially accompanied by changes in the WBC count population, followed by changes within the individual WBCs. Leukocytosis usually occurs by way of increase in a single WBC family rather than a proportional increase in all cell types. Toxic granulation and vacuolation are commonly seen in leukocytosis accompanied by a shift to the left, or increase in the percentage of immature band neutrophils to mature segmented neutrophils. Bandemia is defined by the presence of greater than 6% band neutrophils in the total neutrophil cell population. These changes in the white cell population are most commonly associated with an infectious process, usually bacterial, but they can occur in healthy individuals who are under stress (in response to epinephrine production), such as women in childbirth and very young infants. The WBC count and differential of a woman in labor or of an actively crying infant may show an overall increase in WBCs with a shift to the left. Before initiating any kind of intervention, it is important to determine whether an increased WBC count is the result of a normal condition involving physiological stress or a pathological process. The use of multiple specimen types may confuse the interpretation of results in infants. Multiple samples from the same collection site (i.e., capillary versus venous) may be necessary to obtain an accurate assessment of the WBC picture in these young patients.

Neutrophils are normally found as the predominant WBC type in the circulating blood. Also called polymorphonuclear cells, they are the body’s first line of defense through the process of phagocytosis. They also contain enzymes and pyogens, which combat foreign invaders.

Lymphocytes are agranular, mono-nuclear blood cells that are smaller than granulocytes. They are found in the next highest percentage in normal circulation. Lymphocytes are classified as B cells and T cells. Both types are formed in the bone marrow, but B cells mature in the bone marrow and T cells mature in the thymus. Lymphocytes play a major role in the body’s natural defense system. B cells differentiate into immunoglobulin-synthesizing plasma cells. T cells function as cellular mediators of immunity and comprise helper/inducer (CD4) lymphocytes, delayed hypersensitivity lymphocytes, cytotoxic (CD8 or CD4) lymphocytes, and suppressor (CD8) lymphocytes.

Monocytes are mononuclear cells similar to lymphocytes, but they are related more closely to granulocytes in terms of their function. They are formed in the bone marrow from the same cells as those that produce neutrophils. The major function of monocytes is phagocytosis. Monocytes stay in the peripheral blood for about 70 hr, after which they migrate into the tissues and become macrophages.

The function of eosinophils is phagocytosis of antigen-antibody complexes. They become active in the later stages of inflammation. Eosinophils respond to allergic and parasitic diseases: They have granules that contain histamine used to kill foreign cells in the body and proteolytic enzymes that damage parasitic worms (see monograph titled “Eosinophil Count”).

Basophils are found in small numbers in the circulating blood. They have a phagocytic function and, similar to eosinophils, contain numerous specific granules. Basophilic granules contain heparin, histamines, and serotonin. Basophils may also be found in tissue and as such are classified as mast cells. Basophilia is noted in conditions such as leukemia, Hodgkin's disease, polycythemia vera, ulcerative colitis, nephrosis, and chronic hypersensitivity states.

**INDICATIONS:**
- Assist in confirming suspected bone marrow depression
- Assist in determining the cause of an elevated WBC count (e.g., infection, inflammatory process)
- Detect hematological disorder, neoplasm, or immunological abnormality
- Determine the presence of a hereditary hematological abnormality
- Monitor the effects of physical or emotional stress
- Monitor the progression of non-hematological disorders, such as chronic obstructive pulmonary disease, malabsorption syndromes, cancer, and renal disease
- Monitor the response to drugs or chemotherapy, and evaluate undesired reactions to drugs that may cause blood dyscrasias
- Provide screening as part of a CBC in a general physical examination, especially on admission to a health care facility or before surgery
- Provide screening as part of a CBC in a general physical examination, especially on admission to a health care facility or before surgery

**RESULT:**

**Increased in:**

**Increased in (leukocytosis):**
- Normal physiological and environmental conditions:
  - Early infancy *(Increases are believed to be related to the physiological stress of birth and metabolic demands of rapid development)*
- Emotional stress *(Due to secretion of epinephrine)*
- Exposure to extreme heat or cold *(Physiological stress)*
- Pregnancy and labor *(WBC counts may be modestly elevated, due to increased neutrophils, into the third trimester and during labor; returning to normal within a week postpartum)*
- Strenuous exercise *(Due to epinephrine secretion; increases are short in duration, minutes to hours)*
- Ultraviolet light *(Physiological stress and possible inflammatory response)*

**Decreased in:**

**Decreased in (leukopenia):**
- Normal physiological conditions:
  - Diurnal rhythms (lowest in the morning)
- Pathological conditions:
  - Alcoholism *(WBC changes associated with nutritional deficiencies of vitamin B₁₂ or folate)*
  - Anemias *(WBC changes associated with nutritional deficiencies of*
vitamin B₁₂ or folate, especially in megaloblastic anemias)
Bone marrow depression (Due to decreased production)
Malaria (Due to hypersplenism)
Malnutrition (WBC changes associated with nutritional deficiencies of vitamin B₁₂ or folate)
Radiation (Physical destruction due to toxic effects of radiation)
Rheumatoid arthritis (Side effect of medications used to treat the condition)
Systemic lupus erythematosus (SLE) and other autoimmune disorders (Side effect of medications used to treat the condition)
Toxic and antineoplastic drugs (Bone marrow suppression)
Very low birth weight neonates (Bone marrow activity is diverted to develop RBCs in response to hypoxia)
Viral infections (Leukopenia, lymphocytopenia, and abnormal lymphocytes may be present in the early stages of viral infections)

Neutrophils increased (neutrophilia):
- Acute hemolysis
- Acute hemorrhage
- Extremes in temperature
- Infectious diseases
- Inflammatory conditions (rheumatic fever, gout, rheumatoid arthritis, vasculitis, myositis)
- Malignancies
- Metabolic disorders (uremia, eclampsia, diabetic ketoacidosis, thyroid storm, Cushing's syndrome)
- Myelocytic leukemia
- Physiological stress (e.g., allergies, asthma, exercise, childbirth, surgery)
- Tissue necrosis (burns, crushing injuries, abscesses, myocardial infarction)
- Tissue poisoning with toxins and venoms

Neutrophils decreased (neutropenia):
- Acromegaly
- Addison's disease
- Anaphylaxis
- Anorexia nervosa, starvation, malnutrition
- Bone marrow depression (viruses, toxic chemicals, overwhelming infection, radiation, Gaucher's disease)
- Disseminated SLE
- Thyrotoxicosis
- Viral infection (mononucleosis, hepatitis, influenza)
- Vitamin B₁₂ or folate deficiency

Lymphocytes increased (lymphocytosis):
- Addison's disease
- Felty's syndrome
- Infections
- Lymphocytic leukemia
- Lymphomas
- Lymphosarcoma
- Myeloma
- Ricketts
- Thyrotoxicosis
- Ulcerative colitis
- Waldenström's macroglobulinemia

Lymphocytes decreased (lymphopenia):
- Antineoplastic drugs
- Aplastic anemia
- Bone marrow failure
- Burns
- Gaucher's disease
- Hemolytic disease of the newborn
- High doses of adrenocorticosteroids
- Hodgkin's disease
- Hypersplenism
- Immunodeficiency diseases
- Malnutrition
- Pernicious anemia
- Pneumonia
- Radiation
- Rheumatic fever
- Septicemia
- Thrombocytopenic purpura
- Toxic chemical exposure
- Transfusion reaction

Monocytes increased (monocytosis):
- Carcinomas
- Cirrhosis
• Collagen diseases
• Gaucher’s disease
• Hemolytic anemias
• Hodgkin’s disease
• Infections
• Lymphomas
• Monocytic leukemia
• Polycythemia vera
• Radiation
• Sarcoidosis
• SLE
• Thrombocytopenic purpura
• Ulcerative colitis

**CRITICAL VALUES:**

Less than 2.5 WBC $\times 10^3$/mm$^3$ or 2500 WBC/mm$^3$

Greater than 30.0 WBC $\times 10^3$/mm$^3$ or 30,000 WBC/mm$^3$

Note and immediately report to the requesting health care provider (HCP) any critically increased or decreased values and related symptoms. The presence of abnormal cells, other morphological characteristics, or cellular inclusions may signify a potentially life-threatening or serious health condition and should be investigated. Examples are hypersegmented neutrophils, agranular neutrophils, blasts or other immature cells, Auer rods, Döhle bodies, marked toxic granulation, or plasma cells.

**INTERFERING FACTORS:**

• Drugs that may decrease the overall WBC count include acetyldigitoxin, acetylsalicylic acid, aminoglutethimide, aminopyrine, aminosalicylic acid, ampicillin, amsacrine, antazoline, anticonvulsants, antineoplastic agents (therapeutic intent), antipyrine, barbiturates, busulfan, carbamamide, carmustine, chlorambucil, chloramphenicol, chlortiane, chloroform, chlorothalidone, cisplatin, colchicine, colistimethate, cycloheximide, cyclophosphamide, cytarbine, dacarbazine, dactinomycin, diaprim, diazepam, diethylpropion, digitalis, dipyriramole, dipyrone, fumagillin, glaucarubin, glucosulfone, hexachlorobenzene, hydroflumethiazide, hydroxychloroquine, iohiouracil, iproniazid, lincomycin, local anesthetics, mafenamic acid, mepazine, meprobamate, mercaptopurine, methotrextate, methylpromazine, mitomycin, paramethadione, parathion, penicillin, phenacemide, phenindione, phenothiazine, pipamazine, prednison (by Coulter S method), primaquine, procarbazine, prochlorperazine, promazine, promethazine, pyrazolones, quinacrine, quinines, radioactive compounds, razoxane, ristocetin, sulf drugs, tamoxifen, tetracycline, thalidomide, thioridazine, tolazamide, tolazoline, tolbutamide, trimethadione, and urethane.

• A significant decrease in basophil count occurs rapidly after intravenous injection of propanidid and thiopental.

• A significant decrease in lymphocyte count occurs rapidly after administration of corticotropin, mechlorethamine, methylsergide, and x-ray therapy; and after mega doses of niacin, pyridoxine, and thiamine.

• Drugs that may increase the overall WBC count include amphetamine, amphotericin B, chloramphenicol, chloroform (normal response to anesthesia), colchicine (leukocytosis follows leukopenia), corticotropin, erythromycin, ether (normal response to anesthesia), fluoxene (normal response to anesthesia), isoflurane (normal response to anesthesia), niacinamide, phenylbutazone, prednison, and quinine.

• Drug allergies may have a significant effect on eosinophil count and may affect the overall WBC count. “Refer to the monograph
titled “Eosinophil Count” for a detailed listing of interfering drugs.

- The WBC count may vary depending on the patient’s position,
  decreasing when the patient is recumbent owing to hemodilution
  and increasing when the patient rises owing to hemoconcentration.
- Venous stasis can falsely elevate results; the tourniquet should
  not be left on the arm for longer than 60 sec.
- Failure to fill the tube sufficiently (i.e., tube less than three-quarters
  full) may yield inadequate sample volume for automated analyzers
  and may be reason for specimen rejection.
- Hemolyzed or clotted specimens should be rejected for analysis.
- The presence of nucleated red blood cells or giant or clumped
  platelets affects the automated WBC, requiring a manual correc-
  tion of the WBC count.
- Care should be taken in evaluating the CBC during the first few hours
  after transfusion.
- Patients with cold agglutinins or monoclonal gammopathies may
  have a falsely decreased WBC count as a result of cell clumping.

Obtain a list of the patient’s current medications, including herbs, nutrition-
al supplements, and nutraceuticals.
Review the procedure with the patient.
Inform the patient that specimen
 collection takes approximately 5 to
 10 min. Address concerns about pain
  and explain that there may be some
discomfort during the venipuncture.

NURSING IMPLICATIONS
AND PROCEDURE

PRETEST:

- Inform the patient that the test is
  primarily used to evaluate viral and
  bacterial infections and to diagnose
  and monitor leukemic disorders.
- Obtain a history of the patient’s
  complaints, including a list of known
  allergens, especially allergies or
  sensitivities to latex.
- Obtain a history of the patient’s
  hematopoietic, immune, and respiratory
  systems, symptoms, and results of pre-
  viously performed laboratory tests and
diagnostic and surgical procedures.
- Note any recent procedures that
  can interfere with test results.

INTRATEST:

- If the patient has a history of allergic
  reaction to latex, avoid the use of
equipment containing latex.
- Instruct the patient to cooperate fully
  and to follow directions. Direct the
  patient to breathe normally and to
  avoid unnecessary movement.
- Observe standard precautions, and
  follow the general guidelines in Appendix
  A. Positively identify the patient, and
  label the appropriate tubes with the cor-
  responding patient demographics, date,
  and time of collection. Perform a
  venipuncture. The specimen should be
  mixed gently by inverting the tube 10
  times. It is stable when stored for up to
  6 hr at room temperature or 24 hr if
  stored refrigerated. In addition, if it is
  anticipated that the specimen will not be
  analyzed within 4 to 6 hr, two blood
  smears should be made immediately
  after the venipuncture and submitted
  with the blood sample.
- Remove the needle and apply direct
  pressure with dry gauze to stop bleed-
ing. Observe venipuncture site for
  bleeding or hematoma formation and
  secure gauze with adhesive bandage.
- Promptly transport the specimen to the
  laboratory for processing and analysis.

POST-TEST:

- A report of the results will be sent to
  the requesting HCP, who will discuss
  the results with the patient.

Nutritional considerations: Infection, fever, sepsis, and trauma can result in an
impaired nutritional status. Malnutrition can occur for many reasons, including
fatigue, lack of appetite, and gastrointestinal distress.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include albumin, antibody, anti-neutrophilic cytoplasmic biopsy bone marrow, biopsy lymph node, complete blood count, culture bacterial (see individually listed culture monographs), culture fungal, culture viral, eosinophil count, ESR, fecal analysis, gram stain, infectious mononucleosis, LAP, complete blood count RBC count, complete blood count RBC indices, complete blood count RBC morphology, UA, and WBC scan.
- Refer to the Hematopoietic, Immune, and Respiratory System tables at the back of the book for related tests by body system.

**Nutritional considerations:** Adequate intake of vitamins A and C are also important for regenerating body stores depleted by the effort exerted in fighting infections. Educate the patient or caregiver regarding the importance of following the prescribed diet.

Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the National Cancer Institute (www.nci.nih.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

---

**Computed Tomography, Abdomen**

**SYNONYM/ACRONYM:** Computed axial tomography (CAT), computed transaxial tomography (CTT), abdominal CT, helical/spiral CT.

**AREA OF APPLICATION:** Abdomen.

**CONTRAST:** With or without oral or IV iodinated contrast medium.

**DESCRIPTION:** Abdominal computed tomography (CT) is a noninvasive procedure used to enhance certain anatomic views of the abdominal structures. It becomes invasive when contrast medium is used. During the procedure the patient lies on a table and is moved in and out of a doughnut-like device called a **gantry**, which houses the x-ray tube and associated electronics. The scanner uses multiple x-ray beams and a series of detectors that rotate around the patient to produce cross-sectional views in a three-dimensional fashion. Differences in tissue density are detected and recorded, and are viewable as computerized digital images. Slices or thin sections of certain anatomic views of the liver, biliary tract, pancreas, kidneys,
spleen, intestines, and vascular system are reviewed to allow differentiations of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected hematomas and aneurysms. The procedure is repeated after intravenous injection of iodinated contrast medium for vascular evaluation or after oral ingestion of contrast medium for evaluation of bowel and adjacent structures. Images can be recorded on photographic or x-ray film or stored in digital format as digitized computer data. Cine scanning is used to produce a series of moving images of the area scanned. The CT scan can be used to guide biopsy needles into areas of abdominal tumors to obtain tissue for laboratory analysis and to guide placement of catheters for drainage of intra-abdominal abscesses. Tumors, before and after therapy, may be monitored with CT scanning.

**INDICATIONS:**
- Assist in differentiating between benign and malignant tumors
- Detect aortic aneurysms
- Detect tumor extension of masses and metastasis into the abdominal area
- Differentiate aortic aneurysms from tumors near the aorta
- Differentiate between infectious and inflammatory processes
- Evaluate cysts, masses, abscesses, renal calculi, gastrointestinal (GI) bleeding and obstruction, and trauma
- Evaluate retroperitoneal lymph nodes
- Monitor and evaluate the effectiveness of medical, radiation, or surgical therapies

**RESULT:**

**Normal findings in:**
- Normal size, position, and shape of abdominal organs and vascular system

**Abnormal findings in:**
- Abdominal abscess
- Abdominal aortic aneurysm
- Adrenal tumor or hyperplasia
- Appendicitis
- Dilatation of the common hepatic duct, common bile duct, or gallbladder
- Hematomas, diverticulitis, gallstones
- Hemoperitoneum
- Hepatic cysts or abscesses
- Pancreatic pseudocyst
- Primary and metastatic neoplasms
- Renal calculi, bowel perforation, and GI bleeding and obstruction
- Splenic laceration, tumor, infiltration, and trauma

**CRITICAL VALUES:**
- Abcess
- Acute GI bleed
- Aortic aneurysm
- Appendicitis
- Aortic dissection
- Bowel perforation
- Bowel obstruction
- Mesenteric torsion
- Tumor with significant mass effect
- Visceral injury; significant solid organ laceration

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

**INTERFERING FACTORS:**

**This procedure is contraindicated for:**
- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the medium
may benefit from premedication with corticosteroids or the use of nonionic contrast medium.

- Patients who are claustrophobic.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.
- Young patients (17 y.o. and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.

Factors that may impair clear imaging:

- Gas or feces in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiologic procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and cause unclear images
- Patients with extreme claustrophobia unless sedation is given before the study
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:

- Complications of the procedure may include hemorrhage, infection at the IV needle insertion site, and cardiac arrhythmias.
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the scanning room with the patient should wear a protective lead apron or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
Ensure that barium studies were performed more than 4 days before the CT scan.
Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.
If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.
Review the procedure with the patient. Explain the purpose of the test and how the procedure is performed. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is performed in a radiology suite usually by a HCP and takes approximately 30 to 60 min.
Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, or sedatives.
Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium, if given.
The patient may be requested to drink approximately 450 mL of a dilute barium solution (approximately 1% barium) beginning 1 hr before the examination. This is administered to distinguish GI organs from the other abdominal organs.
Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

The patient should fast and restrict fluids for 8 hr prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility. Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure the patient has complied with dietary, fluids, and medication restrictions for 8 hr prior to the procedure.
- Ensure the patient has removed all external metallic objects from the area to be examined.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Establish an IV fluid line for the injection of contrast, emergency drugs, and sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in the supine position on an exam table.
- If IV contrast media is used, during and after injection a rapid series of images is taken.
Instruct the patient to inhale deeply and hold his or her breathe while the x-ray images are taken, and then to exhale after the images are taken.
Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.
The needle is removed, and a pressure dressing is applied over the puncture site.
Observe the needle site for bleeding, inflammation, or hematoma formation.

**POST-TEST:**

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- If contrast was used, advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the insertion site as needed, to reduce discomfort or edema.
- Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
- Inform the patient that diarrhea may occur after ingestion of oral contrast medium.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ACTH and challenge tests, amylase, angiography abdomen, biopsy intestinal, BUN, calculus kidney stone panel, cortisol and challenge tests, creatinine, cystoscopy, hepatobiliary scan, IVP, KUB studies, MRI abdomen, peritoneal fluid analysis, renogram, and US pelvis.
- Refer to the Gastrointestinal, Hepatobiliary and Genitourinary System tables at the back of the book for related tests by body system.

Computed Tomography, Angiography

**SYNONYM/ACRONYM:** Computed axial tomography (CAT) angiography, CTA.

**AREA OF APPLICATION:** Vessels.

**CONTRAST:** IV iodinated contrast medium.

**DESCRIPTION:** Computed tomography angiography (CTA) is a non-invasive procedure that enhances certain anatomic views of vascular structures. This procedure complements traditional angiography and allows reconstruction of the images in different planes and removal of surrounding structures, leaving only the vessels to be studied. While lying on a table, the patient moves in and out of a doughnut-like device called a gantry, which houses the x-ray tube and associated electronics. The scanner uses multiple x-ray beams and a series of detectors that rotate around the patient to produce cross-sectional views in a three-dimensional fashion by detecting and recording differences in tissue density after having an x-ray beam passed through the tissues. CTA uses spiral CT technology and collects large amounts of data with each scan. Retrospectively, the data can be manipulated to produce the desired image without exposure to additional radiation or contrast medium. Multiplanar reconstruction images are reviewed by the health care provider (HCP) at a computerized workstation. These images are helpful when there are heavily calcified vessels. The axial images give the most precise information regarding the true extent of stenosis, and they can also evaluate intracerebral aneurysms. Small ulcerations and plaque irregularity are readily seen with CTA; the degree of stenosis can be estimated better with CTA because of the increased number of imaging planes. Density measurements are sent to a computer that produces a digital image of the anatomy, enabling the HCP to look at slices or thin sections of certain anatomic views of the vessels. Iodinated contrast medium is given IV for vascular evaluation. Images can be recorded on photographic or x-ray film or stored in digital format as digitized computer data.

**INDICATIONS:**
- Detect aneurysms
- Detect embolism or other occlusions
- Detect fistula
- Detect stenosis
- Detect vascular disease
- Differentiate aortic aneurysms from tumors near the aorta
- Differentiate between vascular and nonvascular tumors
- Evaluate atherosclerosis
- Evaluate hemorrhage or trauma
- Monitor and evaluate the effectiveness of medical or surgical therapies

**RESULT:**

_Normal findings in:_
- Normal size, position, and shape of vascular structures
Abnormal findings in:
- Aortic aneurysm
- Cysts or abscesses
- Emboli
- Hemorrhage
- Neoplasm
- Occlusion
- Shunting
- Stenosis

CRITICAL VALUES:
- Brain or spinal cord ischemia
- Emboli
- Hemorrhage
- Leaking aortic aneurysm
- Occlusion
- Tumor with significant mass effect

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients who are claustrophobic.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.
- Young patients (17 y.o. and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.

Factors that may impair clear imaging:
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and cause unclear images
- Patients who are very obese, or who may exceed the weight limit for the equipment
- Patients with extreme claustrophobia unless sedation is given before the study
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
- Complications of the procedure include hemorrhage, infection at the IV needle insertion site, and cardiac arrhythmias.
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with the HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the scanning room with the patient should wear a protective lead apron or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
C

NURSING IMPLICATIONS

AND PROCEDURE

PRETEST:

Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
Inform the patient that the procedure assesses the cardiovascular system.
Obtain a history of the patient’s complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast mediums.
Obtain a history of patient’s cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.
Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a radiology suite by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, or sedatives.
Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.
Instruct the patient to remove all external metallic objects from the area to be examined.
The patient should fast and restrict fluids for 8 hr prior to the procedure.
Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility.
Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

Ensure that the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.
Ensure that the patient has removed all external metallic objects from the area to be examined.
If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
Have emergency equipment readily available.
Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Establish an IV fluid line for the injection of contrast, emergency drugs, and sedatives.

Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

Place the patient in the supine position on an exam table.

The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to examine the vessels after a time and to monitor the venous phase of the procedure.

Ask the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.

Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

The needle or vascular catheter is removed and a pressure dressing is applied over the puncture site.

Observe the needle site for bleeding, inflammation, or hematoma formation.

POST-TEST:

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume pretesting diet, as directed by the HCP.

Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods. Renal function should be assessed before metformin is resumed.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting. Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.

Instruct the patient in the care and assessment of the site and to observe for bleeding, hematoma formation, bile leakage, and inflammation. Any pleuritic pain, persistent right shoulder pain, or abdominal pain should be reported to the appropriate HCP.

Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.

Instruct the patient to maintain bed rest for 4 to 6 hr after the procedure or as ordered.

Instruct the patient to increase fluid intake to help eliminate the contrast medium.

**Nutritional considerations:** A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.

Inform the patient that diarrhea may occur after ingestion of oral contrast medium.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the...
Computed Tomography, Biliary Tract and Liver

SYNONYM/ACRONYM: Computed axial tomography (CAT), computed transaxial tomography (CTT), abdominal CT, helical/spiral CT.

AREA OF APPLICATION: Liver, biliary tract, and adjacent structures.

CONTRAST: With or without IV iodinated contrast medium.

DESCRIPTION: Computed tomography (CT) of the liver and biliary tract is a noninvasive procedure that enhances certain anatomic views of these structures. It becomes invasive with the use of contrast medium. During the procedure the patient lies on a table and is moved in and out of a doughnut-like device called a gantry, which houses the x-ray tube and associated electronics. The scanner uses multiple x-ray beams and a series of detectors that rotate around the patient to produce cross-sectional views in a three-dimensional fashion. Differences in tissue density are detected and recorded, and are viewable as computerized digital images. Slices or thin sections of certain anatomic views of the kidneys and associated vascular system are reviewed to allow differentiation of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected hematomas and aneurysms. The procedure is repeated after IV injection of iodinated contrast medium for vascular evaluation or after oral ingestion of contrast medium for evaluation of bowel and adjacent structures. Images can be recorded on photographic or x-ray film or stored in digital format as digitized computer data. Cine scanning produces a series of moving images of the scanned
area. The CT scan can be used to guide biopsy needles into areas of liver and biliary tract masses to obtain tissue for laboratory analysis and for placement of needles to aspirate cysts or abscesses. CT scanning can monitor mass, cyst, or tumor growth and post-therapy response.

**INDICATIONS:**
- Assist in differentiating between benign and malignant tumors
- Detect dilation or obstruction of the biliary ducts with or without calcification or gallstone
- Detect liver abnormalities, such as cirrhosis with ascites and fatty liver
- Detect tumor extension of masses and metastasis into the hepatic area
- Differentiate aortic aneurysms from tumors near the aorta
- Differentiate between obstructive and nonobstructive jaundice
- Differentiate infectious from inflammatory processes
- Evaluate hepatic cysts, masses, abscesses, and hematomas, or hepatic trauma
- Monitor and evaluate effectiveness of medical, radiation, or surgical therapies

**RESULT:**

**Normal findings in:**
- Normal size, position, and contour of the liver and biliary ducts

**Abnormal findings in:**
- Dilation of the common hepatic duct, common bile duct, or gallbladder
- Gallstones
- Hematomas
- Hepatic cysts or abscesses
- Jaundice (obstructive or nonobstructive)
- Primary and metastatic neoplasms

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

This procedure is contraindicated for:
- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients who are claustrophobic.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.
- Young patients (17 y.o. and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.

Factors that may impair clear imaging:
- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Patients who are very obese, or who may exceed the weight limit for the equipment
- Patients with extreme claustrophobia unless sedation is given before the study
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
• Complications of the procedure include hemorrhage, infection at the IV needle insertion site, and cardiac arrhythmias.
• The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
• Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the scanning room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➧ Inform the patient that the procedure assesses the liver, biliary tract, and adjacent structures.
➧ Obtain a history of the patient’s complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
➧ Obtain a history of results of the patient’s GI, hepatobiliary and genitourinary systems, symptoms, and previously performed laboratory tests and diagnostic and surgical procedures.
➧ Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
➧ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
➧ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
➧ Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.
➧ If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.
➧ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
➧ Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, or sedatives.
Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium, if given.

The patient may be requested to drink approximately 450 mL of a dilute barium solution (approximately 1% barium) beginning 1 hr before the examination. This is administered to distinguish GI organs from the other abdominal organs.

Instruct the patient to remove all external metallic objects from the area to be examined.

The patient should fast and restrict fluids for 8 hr prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

Ensure the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations for 8 hr prior to the procedure.

Ensure the patient has removed all external metallic objects from the area to be examined.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

**POST-TEST:**

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
If contrast was used, advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

Observe the needle insertion site for bleeding, inflammation, or hematoma formation.

Instruct the patient to apply cold compresses to the insertion site as needed, to reduce discomfort or edema.

Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.

Inform the patient that diarrhea may occur after ingestion of oral contrast media.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHIES:**

- Related tests include ALT, AST, bilirubin, biopsy liver, BUN, creatinine, GGT, hepatobiliary scan, KUB, liver and spleen scan, MRI abdomen, PT/INR, and US liver.
- Refer to the Gastrointestinal, Hepatobiliary, and Genitourinary System tables at the back of the book for related tests by body system.

**SYNONYM/ACRONYM:** Computed axial tomography (CAT) of the head, computed transaxial tomography (CTT) of the head, brain CT, helical/spiral CT.

**AREA OF APPLICATION:** Brain.

**CONTRAST:** With or without IV iodinated contrast medium.

**DESCRIPTION:** Computed tomography (CT) of the brain is a noninvasive procedure used to assist in diagnosing abnormalities of the head, brain tissue, cerebrospinal fluid, and blood circulation. It becomes invasive if contrast medium is used. The patient lies on a table and is moved in and out of a doughnut-like device called a gantry, which houses the x-ray tube and associated electronics. The scanner uses multiple x-ray beams and a series of detectors that rotate around the patient to produce cross-sectional views in a three-dimensional fashion.
Differences in tissue density are detected and recorded, and are viewable as computerized digital images for the health care provider (HCP) to look at. Slices or thin sections of certain anatomic views of the brain and associated vascular system are viewed to allow differentiations of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected hematomas or aneurysms. The procedure is repeated after intravenous injection of iodinated contrast medium for vascular evaluation. Images can be recorded on photographic or x-ray film or stored in digital format as digitized computer data. Cine scanning is used to produce a series of moving images of the area scanned. Tumor progression, before and after therapy, and effectiveness of medical interventions may be monitored by CT scanning.

**INDICATIONS:**
- Detect brain infection, abscess, or necrosis, as evidenced by decreased density on the image
- Detect ventricular enlargement or displacement by increased cerebrospinal fluid
- Determine benign and cancerous intracranial tumors and cyst formation, as evidenced by changes in tissue densities
- Determine cause of increased intracranial pressure
- Determine presence and type of hemorrhage in infants and children experiencing signs and symptoms of intracranial trauma, or congenital conditions such as hydrocephalus and arteriovenous malformations (AVMs)
- Determine presence of multiple sclerosis, as evidenced by sclerotic plaques
- Determine lesion size and location causing infarct or hemorrhage
- Differentiate hematoma location after trauma (e.g., subdural, epidural, cerebral), and determine extent of edema, as evidenced by higher blood densities
- Differentiate between cerebral infarction and hemorrhage
- Evaluate abnormalities of the middle ear ossicles, auditory nerve, and optic nerve
- Monitor and evaluate the effectiveness of medical, radiation, or surgical therapies

**RESULT:**

*Normal findings in:*
- Normal size, position, and shape of intracranial structures and vascular system

*Abnormal findings in:*
- Abscess
- Aneurysm
- AVMs
- Cerebral atrophy
- Cerebral edema
- Cerebral infarction
- Congenital abnormalities
- Craniopharyngioma
- Cysts
- Hematomas (e.g., epidural, subdural, intracerebral)
- Hemorrhage
- Hydrocephaly
- Increased intracranial pressure or trauma
- Infection
- Sclerotic plaques suggesting multiple sclerosis
- Tumor
- Ventricular or tissue displacement or enlargement
CRITICAL VALUES:
- Abcess
- Acute hemorrhage
- Aneurysm
- Infarction
- Infection
- Tumor with significant mass effect

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction.
- Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients who are claustrophobic.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.
- Young patients (17 y.o. and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.

Factors that may impair clear imaging:
- Metallic objects (e.g., jewelry, dentures, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Patients who are very obese, or who may exceed the weight limit for the equipment
- Patients with extreme claustrophobia unless sedation is given before the study
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
- Complications of the procedure may include hemorrhage, infection at the IV needle insertion site, and cardiac arrhythmias.
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with the HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the scanning room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the brain.
- Obtain a history of the patient’s complaints or clinical symptoms, including
a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.

Obtain a history of the patient’s musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.

Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.

If contrast media is scheduled to be used, patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.

Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by a HCP specializing in this procedure, with support staff, and takes approximately 15 to 30 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually contrast medium and normal saline are infused.

Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.

Instruct the patient to remove dentures and jewelry and other metallic objects from the area to be examined.

There are no food or fluid restrictions unless by medical direction. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

Ensure the patient has complied with medication restrictions and pretesting preparations.

Ensure the patient has removed dentures and all external metallic objects from the area to be examined prior to the procedure.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.

Have emergency equipment readily available.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Establish an IV fluid line for the injection of contrast medium, emergency drugs, and sedatives.
Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
Place the patient in the supine position on an exam table.
If contrast media is used, a rapid series of images is taken during and after injection.
Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.
The needle is removed, and a pressure dressing is applied over the puncture site.
Observe the needle insertion site for bleeding, inflammation, or hematoma formation.

**POST-TEST:**

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
Instruct the patient to resume medications and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

If contrast was used, advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
Observe the needle insertion site for bleeding, inflammation, or hematoma formation.
Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
Inform the patient that diarrhea may occur after ingestion of oral contrast medium.
Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include angiography carotids, BUN, CSF analysis, CT angiography, creatinine, EEG, EMG, MR angiography, and MRI brain, PET brain.
Refer to the Musculoskeletal System table at the back of the book for related tests by body system.
**Computed Tomography, Cardiac Scoring**

**SYNONYM/ACRONYM:** Computed axial tomography (CAT), computed transaxial tomography (CTT), heart vessel calcium CT, helical/spiral CT, cardiac plaque CT.

**AREA OF APPLICATION:** Heart.

**CONTRAST:** None.

**DESCRIPTION:** Cardiac scoring is a noninvasive test for quantifying coronary artery calcium content. Coronary artery disease (CAD) occurs when the arteries that carry blood and oxygen to the heart muscle become clogged or built up with plaque. Plaque buildup slows the flow of blood to the heart muscle, causing ischemia and increasing the risk of heart failure. The procedure begins with a computed tomography (CT) scan of the heart. The patient lies on a table and is moved in and out of a doughnut-like device called a gantry, which houses the x-ray tube and associated electronics. The scanner uses multiple x-ray beams and a series of detectors that rotate around the patient to produce cross-sectional views in a three-dimensional fashion by detecting and recording differences in plaque density after having an x-ray beam passed through the tissues. The scanner takes an image of the beating heart while the patient holds his or her breathe for approximately 20 sec. The procedure requires no contrast medium injections. These density measurements are sent to a computer that produces a digital analysis of the anatomy, enabling the health care provider (HCP) to look at the quantified amount of calcium (cardiac plaque score) in the coronary arteries. The data can be recorded on photographic or x-ray film or stored in digital format as digitized computer data.

**INDICATIONS:**
- Detect and quantify coronary artery calcium content
  - CAD is the leading cause of death in most industrialized nations
  - Cardiac scoring is a more powerful predictor of CAD than cholesterol screening
- Of all myocardial infarctions (MIs), 45% occur in people younger than age 65
- Of women who have had MIs, 44% will die within 1 yr after the attack
- Women are more likely to die of heart disease than of breast cancer
- Family history of heart disease
- Screening for coronary artery calcium in patients with:
  - Diabetes
  - High blood pressure
  - High cholesterol
  - High-stress lifestyle
  - Overweight by 20% or more
  - Personal history of smoking
  - Sedentary lifestyle
- Screening for coronary artery plaque in patients with chest pain of unknown cause
RESULT:

Normal findings in:
• If the score is 100 or less, the probability of having significant CAD is minimal or is unlikely to be causing a narrowing at the time of the examination.

Abnormal findings in:
• If the score is between 101 and 400, a significant amount of calcified plaque was found in the coronary arteries. There is an increased risk of a future MI, and a medical assessment of cardiac risk factors needs to be done. Additional testing may be needed.
• If the score is greater than 400, the procedure has detected extensive calcified plaque in the coronary arteries, which may have caused a critical narrowing of the vessels. A full medical assessment is needed as soon as possible. Further testing may be needed, and treatment may be needed to reduce the risk of MI.

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients who are claustrophobic.
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
• Young patients (17 y.o. and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.

Factors that may impair clear imaging:
• Retained barium or radiological contrast from a previous radiological procedure
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
• Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
• Patients with extreme claustrophobia unless sedation is given before the study
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
• The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
• Consultation with the HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the scanning room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses the coronary arteries.
Obtain a history of the patient’s complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.

Obtain a history of patient’s coronary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.

Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.

Ensure that barium studies were performed more than 4 days before the CT scan.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.

If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.

Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, or sedatives.

Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium, if given.

The patient should not fast or restrict fluids prior to the procedure. Protocols may vary from facility to facility.

Instruct the patient to remove all external metallic objects from the area to be examined.

**INTRATEST:**

Ensure the patient has complied with pretesting preparations.

Ensure that the patient has removed all external metallic objects from the area to be examined.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions.

Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

Observe standard precautions, and follow the general guidelines in Appendix A.

Establish an IV fluid line for the injection of contrast medium, emergency drugs, and sedatives.

Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative...
to a child or to an uncooperative adult, as ordered.

- Place the patient in the supine position on an exam table.
- A rapid series of images is taken of the vessels to be examined.
- Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.
- The needle is removed, and a pressure dressing is applied over the puncture site.
- Observe the needle site for bleeding, inflammation, or hematoma formation.

**POST-TEST:**

- A report of the examination will be sent to the requesting HCP who will discuss the results with the patient.
- Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypotension, palpitations, nausea, or vomiting.
- If contrast was used, advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle insertion site for bleeding, inflammation, or hematoma formation.

**RELATED MONOGRAPHS:**

- Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, atrial natriuretic peptide, BNP, BUN, calcium, chest x-ray, cholesterol (total, HDL, LDL), CRP, coronary angiography, CT thorax, CK and isoenzymes, creatinine echocardiography, echocardiography transesophageal ECG, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, lung scan, magnesium, MRI chest, MI scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, triglycerides, and troponin.

Refer to the Cardiovascular System table at the back of the book for related tests by body system.
**Computed Tomography, Colonoscopy**

**SYNONYM/ACRONYM:** Computed axial tomography (CAT), computed transaxial tomography (CTT), CT virtual colonoscopy, CT colonography.

**AREA OF APPLICATION:** Colon.

**CONTRAST:** Screening examinations are done without IV iodinated contrast medium. Examinations done to clarify questionable or abnormal areas may require IV iodinated contrast medium.

**DESCRIPTION:** Computed tomography (CT) colonoscopy is a non-invasive technique that involves examining the colon by taking multiple CT scans of the patient’s colon and rectum and using computer software to create three-dimensional images. The procedure is used to detect polyps, which are growths of tissue in the colon or rectum. Some types of polyps increase the risk of colon cancer, especially if they are large or if a patient has several polyps. Compared to conventional colonoscopy, CT colonoscopy is less effective in detecting polyps smaller than 5 mm, more effective when the polyps are between 5 and 9.9 mm, and most effective when the polyps are 10 mm or larger. This test may be valuable for patients who have diseases rendering them unable to undergo conventional colonoscopy (e.g., bleeding disorders, lung or heart disease) and for patients who are unable to undergo the sedation required for traditional colonoscopy. The procedure is less invasive than conventional colonoscopy, with little risk of complications and no recovery time. CT colonoscopy can be done as an outpatient procedure, and the patient may return to work or usual activities the same day.

CT colonoscopy and conventional colonoscopy require the bowel to be cleansed before the examination. The patient lies on a table and is moved in and out of a doughnut-like device called a gantry, which houses the x-ray tube and associated electronics. The scanner uses multiple x-ray beams and a series of detectors that rotate around the patient to produce cross-sectional views in a three-dimensional fashion by detecting and recording differences in densities in the colon after having an x-ray beam passed through it. The screening procedure requires no contrast medium injections, but if a suspicious area or abnormality is detected, a repeat series of images may be completed after IV contrast medium is given. These density measurements are sent to a computer that produces a digital analysis of the anatomy, enabling a health care provider (HCP) to look at slices or thin sections of certain anatomic views of the colon and vascular system. The data can be recorded on photographic or x-ray film or stored in digital format as digitized computer data.
A drawback of CT colonoscopy is that polyp removal and biopsies of tissue in the colon must be done using conventional colonoscopy. Therefore, if polyps are discovered during CT colonoscopy and biopsy becomes necessary, the patient must undergo bowel preparation a second time.

**INDICATIONS:**
- Detect polyps in the colon
- Evaluate the colon for metachronous lesions
- Evaluate the colon in patients with obstructing rectosigmoid disease
- Evaluate polyposis syndromes
- Evaluate the site of resection for local recurrence of lesions
- Examine the colon in patients with heart or lung disease, patients unable to be sedated, and patients unable to undergo colonoscopy
- Failure to visualize the entire colon during conventional colonoscopy
- Identify metastases
- Investigate cause of positive occult blood test
- Investigate further after an abnormal barium enema
- Investigate further when flexible sigmoidoscopy is positive for polyps

**RESULT:**

**Normal findings in:**
- Normal colon and rectum, with no evidence of polyps or growths

**Abnormal findings in:**
- Abnormal endoluminal wall of the colon
- Extraluminal extension of primary cancer
- Mesenteric and retroperitoneal lymphadenopathy
- Metachronous lesions
- Metastases of cancer
- Polyps or growths in colon or rectum
- Tumor recurrence after surgery

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

*This procedure is contraindicated for:*
- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium, if contrast is used.
- Patients who are claustrophobic.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure, if contrast is used.
- Patients who are in renal failure, if contrast is used.
- Young patients (17 y.o. and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.

*Factors that may impair clear imaging:*
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Patients who are very obese, or who may exceed the weight limit for the equipment
• Patients with extreme claustrophobia unless sedation is given before the study
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
• Complications of the procedure may include hemorrhage, infection at the IV needle insertion site, and cardiac arrhythmias.
• The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
• Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
• Consultation with the HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the scanning room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➧ Inform the patient that the procedure assesses the colon.
➧ Obtain a history of the patient’s complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast mediums.

Obtain a history of the patient’s gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.

Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.

If contrast is scheduled to be used, patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.

Review the procedure with the patient. Address concerns about pain and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a radiology department, usually by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives.

Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a
transient headache after injection of contrast medium.

- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- The patient should fast and restrict fluids for 6 to 8 hr prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure that the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations; assure that food and fluids have been restricted for at least 6 hr prior to the procedure.
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Establish an IV fluid line for the injection of contrast (if used), emergency drugs, and sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

- Place the patient in the supine position on an exam table.
- The colon is distended with room air or carbon dioxide by means of a rectal tube and balloon retention device. Maximal colonic distention is guided by patient tolerance.
- If IV contrast is used, a rapid series of images is taken during and after injection.
- Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- The sequence of images is repeated in the prone position.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.
- The needle is removed, and a pressure dressing is applied over the puncture site.
- Observe the needle site for bleeding, inflammation, or hematoma formation.

**POST-TEST:**

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- If contrast was used, advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.

Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.

Inform the patient that diarrhea may occur after ingestion of oral contrast media.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.

Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include barium enema, BUN, cancer antigens (CA 19–9), CEA, colonoscopy, CT abdomen, creatinine, fecal analysis, KUB studies, MRI abdomen, PET pelvis, proctosigmoidoscopy, and US pelvis.
- Refer to the Gastrointestinal System table at the back of the book for related tests by body system.

SYNONYM/ACRONYM: Computed axial tomography (CAT), computed transaxial tomography (CTT, abdominal CT, helical/spiral CT).

AREA OF APPLICATION: Pancreas.

CONTRAST: With or without oral or IV iodinated contrast medium.

DESCRIPTION: Computed tomography (CT) is a noninvasive procedure used to enhance certain anatomic views of the abdominal structures. It becomes an invasive procedure when contrast medium is used. CT of the pancreas aids in the diagnosis or evaluation of pancreatic cysts, pseudocysts, inflammation, tumors, masses, metastases, abscesses, and trauma. In all but the thinnest or most emaciated patients, the pancreas is surrounded by fat that clearly defines its margins. During the procedure the patient lies on a table and is moved in and out of a doughnut-like device called a gantry, which houses the x-ray tube and associated electronics. The scanner uses multiple x-ray beams and a series of detectors that rotate around the patient to produce cross-sectional views in a three-dimensional fashion. Differences in tissue density are detected and recorded, and are viewable as computerized digital images. Slices or thin sections of certain anatomic views of the
Kidneys and associated vascular system are reviewed to allow differentiation of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected hematomas and aneurysms. The procedure is repeated after intravenous injection of iodinated contrast medium for vascular evaluation or after oral ingestion of contrast medium for evaluation of bowel and adjacent structures. Images can be recorded on photographic or x-ray film or stored in digital format as digitized computer data. Cine scanning produces a series of moving images of the scanned area. The CT scan can be used to guide biopsy needles into areas of pancreatic masses to obtain tissue for laboratory analysis and for placement of needles to aspirate cysts or abscesses. CT scanning can monitor mass, cyst, or tumor growth and post-therapy response.

**INDICATIONS:**
- Detect dilation or obstruction of the pancreatic ducts
- Differentiate between pancreatic disorders and disorders of the retroperitoneum
- Evaluate benign or cancerous tumors or metastasis to the pancreas
- Evaluate pancreatic abnormalities (e.g., bleeding, pancreatitis, pseudocyst, abscesses)
- Evaluate unexplained weight loss, jaundice, and epigastric pain
- Monitor and evaluate effectiveness of medical or surgical therapies

**RESULT:**

**Normal findings in:**
- Normal size, position, and contour of the pancreas, which lies obliquely in the upper abdomen

**Abnormal findings in:**
- Acute or chronic pancreatitis
- Obstruction of the pancreatic ducts
- Pancreatic abscesses
- Pancreatic carcinoma
- Pancreatic pseudocyst
- Pancreatic tumor

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

- **This procedure is contraindicated for:**
  - Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
  - Patients who are claustrophobic.
  - Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
  - Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
  - Patients who are in renal failure.
  - Young patients (17 y.o. and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.

**Factors that may impair clear imaging:**
- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
• Patients who are very obese, or who may exceed the weight limit for the equipment
• Patients with extreme claustrophobia unless sedation is given before the study
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
• Complications of the procedure include hemorrhage, infection at the IV needle insertion site, and cardiac arrhythmias.
• The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
• Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the scanning room with the patient should wear a protective lead apron or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses the abdomen and pancreatic area.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics or other contrast medium.
• Obtain a history of the patient’s GI, hepatobiliary, and genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
• Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
• Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.
• If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.
• Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually contrast medium and normal saline are infused.
• Inform the patient that he or she may experience nausea, a feeling of...
warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.

The patient should fast and restrict fluids for 2 to 4 hr prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility.

The patient may be requested to drink approximately 450 mL of a dilute barium solution (approximately 1% barium) beginning 1 hr before the examination. This is administered to distinguish GI organs from the other abdominal organs.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations; assure that food and fluids have been restricted for at least 2 to 4 hr prior to the procedure.
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Establish an IV fluid line for the injection of contrast medium, emergency drugs, and sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in the supine position on an exam table.
- If IV contrast medium is used, a rapid series of images is taken during and after injection.
- Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.
- The needle is removed, and a pressure dressing is applied over the puncture site.
- Observe the needle site for bleeding, inflammation, or hematoma formation.

**POST-TEST:**

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- If contrast was used, advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
Inform the patient that diarrhea may occur after ingestion of oral contrast medium.
Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include amylase, angiography of the abdomen, biopsy intestinal, BUN, CA 125, CA 19–9, creatinine, ERCP, lipase, MRI abdomen, and US pancreas.
- Refer to the Gastrointestinal, Hepatobiliary, and Genitourinary System tables at the back of the book for related tests by body system.

**SYNONYM/ACRONYM:** Computed axial tomography (CAT), computed transaxial tomography (CTT), pelvic CT, helical/spiral CT.

**AREA OF APPLICATION:** Pelvis.

**CONTRAST:** With or without oral or IV iodinated contrast medium.

**DESCRIPTION:** Computed tomography (CT) of the pelvis is a noninvasive procedure used to enhance certain anatomic views of the pelvic structures. It becomes an invasive procedure when intravenous contrast medium is used. During the procedure the patient lies on a table and is moved in and out of a doughnut-like device called a *gantry*, which houses the x-ray tube and associated electronics. The scanner uses multiple x-ray beams and a series of detectors that rotate around the patient to produce cross-sectional views in a three-dimensional fashion. Differences in tissue density are detected and recorded, and are viewable as computerized digital images. Slices or thin sections of certain anatomic views of the pelvic structures and associated vascular system are reviewed to allow differentiation of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected hematomas and aneurysms. The procedure is repeated after intravenous injection of iodinated contrast medium for vascular evaluation or after oral ingestion of contrast.
medium for evaluation of bowel and adjacent structures. Images can be recorded on photographic or x-ray film or stored in digital format as digitized computer data. Cine scanning produces a series of moving images of the scanned area. The CT scan can be used to guide biopsy needles into areas of pelvic masses to obtain tissue for laboratory analysis and for placement of needles to aspirate cysts or abscesses. CT scanning can monitor mass, cyst, or tumor growth and post-therapy response.

**INDICATIONS:**
- Assist in differentiating between benign and malignant tumors
- Detect tumor extension of masses and metastasis into the pelvic area
- Differentiate infectious from inflammatory processes
- Evaluate pelvic lymph nodes
- Evaluate cysts, masses, abscesses, ureteral and bladder calculi, gastrointestinal (GI) bleeding and obstruction, and trauma
- Monitor and evaluate effectiveness of medical, radiation, or surgical therapies

**RESULT:**

**Normal findings in:**
- Normal size, position, and shape of pelvic organs and vascular system

**Abnormal findings in:**
- Bladder calculi
- Ectopic pregnancy
- Fibroid tumors
- Hydrosalpinx
- Ovarian cyst or abscess
- Primary and metastatic neoplasms

**CRITICAL VALUES:**
- Ectopic pregnancy
- Tumor with significant mass effect

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

**INTERFERING FACTORS:**

* This procedure is contraindicated for:
  - Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
  - Patients who are claustrophobic.
  - Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
  - Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
  - Patients who are in renal failure.
  - Young patients (17 y.o. and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.

* Factors that may impair clear imaging:
  - Gas or feces in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study
  - Retained barium from a previous radiological procedure
  - Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and can produce unclear images
  - Patients who are very obese, or who may exceed the weight limit for the equipment
  - Patients with extreme claustrophobia unless sedation is given before the study
Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
- Complications of the procedure include hemorrhage, infection at the IV needle insertion site, and cardiac arrhythmias.
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the scanning room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

Obtain a history of the patient’s GI, reproductive, and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.

Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.

Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually contrast medium and normal saline are infused.

Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the pelvis and pelvic organs.
- Obtain a history of the patient’s complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
The patient should fast and restrict fluids for 2 to 4 hr prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility.

The patient may be requested to drink approximately 450 mL of a dilute barium solution (approximately 1% barium) beginning 1 hr before the examination. This is administered to distinguish GI organs from the other abdominal organs.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

Ensure the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations; assure that food and fluids have been restricted for at least 2 to 4 hr prior to the procedure.

Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Establish an IV fluid line for the injection of contrast, emergency drugs, and sedatives.

Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

Place the patient in the supine position on an exam table.

If IV contrast medium is used, a rapid series of images is taken during and after injection.

Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.

Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.

The needle is removed, and a pressure dressing is applied over the puncture site.

Observe the needle site for bleeding, inflammation, or hematoma formation.

**POST-TEST:**

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

If contrast was used, advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

Observe the needle insertion site for bleeding, inflammation, or hematoma formation.

Instruct the patient to apply cold compresses to the insertion site as needed, to reduce discomfort or edema.
Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
Inform the patient that diarrhea may occur after ingestion of oral contrast medium.
Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include angiography pelvis, barium enema, BUN, calculus kidney stone panel, carcinoembrionic and cancer antigens, creatinine, HCG, IVP, KUB film, MRI abdomen, proctosigmoidoscopy, UA, and US pelvis.
- Refer to the Gastrointestinal, Reproductive, and Genitourinary System tables at the back of the book for related tests by body system.

**SYNONYM/ACRONYM:** Computed axial tomography (CAT), computed transaxial tomography (CTT), pituitary CT, helical/spiral CT.

**AREA OF APPLICATION:** Pituitary/brain.

**CONTRAST:** With or without IV iodinated contrast medium.

**DESCRIPTION:** Computed tomography (CT) of the pituitary is a noninvasive procedure that enhances certain anatomic views of the pituitary gland and perisel lar region. It becomes invasive when a contrast medium is used. This procedure aids in the evaluation of pituitary adenoma, craniohypophysealoma, meningioma, aneurysm, metastatic disease, exophthalmos, and cysts. Visualization of bony septa in the sphenoid sinus and evaluation for nonpneumatization of the sphenoid sinus are best performed with this procedure. During the procedure the patient lies on a table and moves in and out of a doughnut-like device called a *gantry*, which houses the x-ray tube and associated electronics. The scanner uses multiple x-ray beams and a series of detectors that rotate around the patient to produce cross-sectional views in a three-dimensional fashion. Differences in tissue density are detected and recorded, and are viewable as...
computerized digital images. Slices or thin sections of certain anatomic views of the pituitary and associated vascular system are reviewed to allow differentiations of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected hematomas and aneurysms. The procedure may be repeated after iodinated contrast medium is given IV for blood vessel and vascular evaluation. Images can be recorded on photographic or x-ray film or stored in digital format as digitized computer data. Cine scanning produces a series of moving images of the scanned area. Tumors, before and after therapy, may be monitored by CT scanning.

INDICATIONS:
- Assist in differentiating between benign and malignant tumors
- Detect aneurysms and vascular abnormalities
- Detect congenital anomalies, such as partially empty sella
- Detect tumor extension of masses and metastasis
- Determine pituitary size and location in relation to surrounding structures
- Evaluate cysts, masses, abscesses, and trauma
- Monitor and evaluate effectiveness of medical, radiation, or surgical therapies

RESULT:

**Normal findings in:**
- Normal size, position, and shape of the pituitary fossa, cavernous sinuses, and vascular system

**Abnormal findings in:**
- Abscess
- Adenoma
- Aneurysm

CRITICAL VALUES: N/A

INTERFERING FACTORS:
*This procedure is contraindicated for:*
- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients who are claustrophobic.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.
- Young patients (17 y.o. and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.

Factors that may impair clear imaging:
- Retained contrast from a previous radiological procedure
- Metallic objects (e.g., jewelry, dentures, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Patients who are very obese, or who may exceed the weight limit for the equipment
- Patients with extreme claustrophobia unless sedation is given before the study
Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
- Complications of the procedure may include hemorrhage, infection at the IV needle insertion site, and cardiac arrhythmias.
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the scanning room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.
- If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.
- Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually contrast medium and normal saline are infused.
- Inform the patient that he or she may experience nausea, a feeling of
warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.

- Instruct the patient to remove dentures and other metallic objects from the area to be examined.

- There are no food or fluid restrictions unless by medical direction. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility.

- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure the patient has complied with medication restrictions and pretesting preparations.
- Ensure the patient has removed dentures and all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Have emergency equipment readily available.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Establish an IV fluid line for the injection of contrast medium, emergency drugs, and sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in the supine position on an exam table.
- If IV contrast medium is used, a rapid series of images is taken during and after injection.

- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast medium is used.
- The needle is removed, and a pressure dressing is applied over the puncture site.
- Observe the needle site for bleeding, inflammation, or hematoma formation.

**POST-TEST:**

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual medications and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- If contrast was used, advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the insertion site as needed, to reduce discomfort or edema.
- Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
- Inform the patient that diarrhea may occur after ingestion of oral contrast medium.
- Recognize anxiety related to test results. Discuss the implications
of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ACTH and challenge tests, BUN, CT angiography, CT brain, cortisol and challenge tests, creatinine, PET brain, MRA, and MRI brain.
- Refer to the Endocrine System table at the back of the book for related tests by body system.

**Computed Tomography, Renal**

**SYNONYM/ACRONYM:** Computed axial tomography (CAT), computed transaxial tomography (CTT), kidney CT, helical/spiral CT.

**AREA OF APPLICATION:** Kidney.

**CONTRAST:** With or without oral or IV iodinated contrast medium.

**DESCRIPTION:** Renal computed tomography (CT) is a noninvasive procedure used to enhance certain anatomic views of the renal structures. It becomes an invasive procedure when contrast medium is used. CT scanning is a safe, rapid method for renal evaluation that is independent of renal function. It provides unique cross-sectional anatomic information and is unsurpassed in evaluating lesions containing fat or calcium. During the procedure the patient lies on a table and is moved in and out of a doughnut-like device called a gantry, which houses the x-ray tube and associated electronics. The scanner uses multiple x-ray beams and a series of detectors that rotate around the patient to produce cross-sectional views in a three-dimensional fashion. Differences in tissue density are detected and recorded, and are viewable as computerized digital images. Slices or thin sections of certain anatomic views of the kidneys and associated vascular system are reviewed to allow differentiation of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected hematomas and aneurysms. The procedure is repeated after IV injection of iodinated contrast medium for vascular evaluation or after oral ingestion of contrast medium for

Access additional resources at davisplus.fadavis.com
evaluation of bowel and adjacent structures. Images can be recorded on photographic or x-ray film or stored in digital format as digitized computer data. Cine scanning produces a series of moving images of the area scanned. The CT scan can be used to guide biopsy needles into areas of suspected tumors to obtain tissue for laboratory analysis and to guide placement of catheters for drainage of renal abscesses. Tumors, before and after therapy, may be monitored with CT scanning.

INDICATIONS:
- Aid in the diagnosis of congenital anomalies, such as polycystic kidney disease, horseshoe kidney, absence of one kidney, or kidney displacement
- Aid in the diagnosis of perirenal hematomas and abscesses and assist in localizing for drainage
- Assist in differentiating between benign and malignant tumors
- Assist in differentiating between an infectious and an inflammatory process
- Detect aneurysms and vascular abnormalities
- Detect bleeding or hyperplasia of the adrenal glands
- Detect tumor extension of masses and metastasis into the renal area
- Determine kidney size and location in relation to the bladder in post-transplant patients
- Determine presence and type of adrenal tumor, such as benign adenoma, cancer, or pheochromocytoma
- Evaluate abnormal fluid accumulation around the kidney
- Evaluate cysts, masses, abscesses, renal calculi, obstruction, and trauma
- Evaluate spread of a tumor or invasion of nearby retroperitoneal organs
- Monitor and evaluate effectiveness of medical, radiation, or surgical therapies

RESULT:

Normal findings in:
- Normal size, position, and shape of kidneys and vascular system

Abnormal findings in:
- Adrenal tumor or hyperplasia
- Congenital anomalies, such as polycystic kidney disease, horseshoe kidney, absence of one kidney, or kidney displacement
- Dilatation of the common hepatic duct, common bile duct, or gallbladder
- Renal artery aneurysm
- Renal calculi and ureteral obstruction
- Renal cell carcinoma
- Renal cysts or abscesses
- Renal laceration, fracture, tumor, and trauma
- Perirenal abscesses and hematomas
- Primary and metastatic neoplasms

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients who are claustrophobic.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.

Patients who are in renal failure.

Young patients (17 y.o. and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.

Factors that may impair clear imaging:

- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Patients who are very obese, or who may exceed the weight limit for the equipment
- Patients with extreme claustrophobia unless sedation is given before the study
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:

- Complications of the procedure include hemorrhage, infection at the IV needle insertion site, and cardiac arrhythmias.
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the scanning room with the patient should wear a protective lead apron or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the kidney.
- Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast mediums.
- Obtain a history of the patient’s GI and genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutriceuticals (see Appendix F). Note the last time and dose of medication taken.

Access additional resources at davisplus.fadavis.com
If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.

Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually contrast medium and normal saline are infused.

*Sensitivity to social and cultural issues*, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. The patient may be requested to drink approximately 450 mL of a dilute barium solution (approximately 1% barium) beginning 1 hr before the examination. This is administered to distinguish GI organs from the other abdominal organs.

Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

The patient should fast and restrict fluids for 2 to 4 hr prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRA.TEST:**

Ensure the patient has complied with dietary, fluids, and medication restrictions for 2 to 4 hr prior to the procedure.

Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Establish an IV fluid line for the injection of contrast, emergency drugs, and sedatives.

Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

Place the patient in the supine position on an exam table.

If IV contrast is used, a rapid series of images is taken during and after injection.

Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.

Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.

The needle is removed, and a pressure dressing is applied over the puncture site.

Observe the needle site for bleeding, inflammation, or hematoma formation.

**POST-TEST:**

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, medications, and activity,
as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.

◆ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

◆ If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

◆ If contrast was used, advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

◆ Observe the needle insertion site for bleeding, inflammation, or hematoma formation.

◆ Instruct the patient to apply cold compresses to the insertion site as needed, to reduce discomfort or edema.

◆ Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.

◆ Inform the patient that diarrhea may occur after ingestion of oral contrast medium.

◆ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

◆ Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

◆ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ACTH, angiography adrenal, renal biopsy, BUN, calculus/kidney stone panel, catecholamines, creatinine, CT abdomen, homovanillic acid, IVP, KUB, MRI abdomen, US renal, and VMA.
- Refer to the Gastrointestinal and Genitourinary System tables at the back of the book for related tests by body system.

---

**Computed Tomography, Spine**

**SYNONYM/ACRONYM:** Computed axial tomography (CAT), computed transaxial tomography (CTT), spine CT, CT myelogram.

**AREA OF APPLICATION:** Spine.

**CONTRAST:** With or without oral or IV iodinated contrast medium.

**DESCRIPTION:** Computed tomography (CT) of the spine is a noninvasive procedure that enhances certain anatomic views of the spinal structures. CT scanning is more versatile than conventional radiography and can easily detect and identify tumors and their types. During the procedure the patient lies on a table and is moved in and out of a doughnut-like device called a *gantry*, which houses the x-ray tube and associated elec-
tronics. The scanner uses multiple x-ray beams and a series of detectors that rotate around the patient to produce cross-sectional views in a three-dimensional fashion. Differences in tissue density are detected and recorded, and are viewable as computerized digital images. Slices or thin sections of certain anatomic views of the spine and associated vascular system are reviewed to allow differentiations of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected hematomas and aneurysms. The procedure may be repeated after intravenous injection of iodinated contrast medium for vascular evaluation. Images can be recorded on photographic or x-ray film or stored in digital format as digitized computer data. Cine scanning produces a series of moving images of the scanned area. CT scanning can be used to guide biopsy needles into areas of suspected tumor to obtain tissue for laboratory analysis and to guide placement of catheters for drainage of abscesses. Tumor size, progression, and pre- and post-therapy changes may be monitored with CT scanning.

**INDICATIONS:**
- Assist in differentiating between benign and malignant tumors
- Detect congenital spinal anomalies, such as spina bifida, meningocele, and myelocoele
- Detect herniated intervertebral disks
- Detect paraspinal cysts
- Detect vascular malformations
- Monitor and evaluate effectiveness of medical, radiation, or surgical therapies

**RESULT:**

*Normal findings in:*
- Normal density, size, position, and shape of spinal structures

*Abnormal findings in:*
- Congenital spinal malformations, such as meningocele, myelocoele, or spina bifida
- Herniated intervertebral disks
- Paraspinal cysts
- Spinal tumors
- Spondylosis (cervical or lumbar)
- Vascular malformations

**CRITICAL VALUES:**
- Cord compression
- Fracture
- Tumor with significant mass effect

Note and immediately report to the health care provider (HCP) positive results and related symptoms.

**INTERFERING FACTORS:**

*This procedure is contraindicated for:*
- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients who are claustrophobic.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.
- Young patients (17 y.o. and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.
Factors that may impair clear imaging:

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Patients who are very obese, or who may exceed the weight limit for the equipment
- Patients with extreme claustrophobia unless sedation is given before the study
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:

- Complications of the procedure may include hemorrhage, infection at the IV needle insertion site, and cardiac arrhythmias.
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the scanning room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the spine and spinal canal.
- Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
- Obtain a history of the patient's musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs and nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.
- If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.
- Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important.
in providing psychological support before, during, and after the procedure.

 navigate an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually contrast medium and normal saline are infused.

 Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.

 Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

 There are no food or fluid restrictions unless by medical direction. Instruct the patient to avoid taking anticoagulant medications or to reduce dosage as ordered prior to the procedure.

 Protocols may vary from facility to facility.

 Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

 **INTRATEST:**

 Ensure that the patient has complied with medication restrictions and pretesting preparations.

 Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.

 If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.

 Have emergency equipment readily available.

 Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

 Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

 Observe standard precautions, and follow the general guidelines in Appendix A.

 If ordered, establish an IV fluid line for the injection of contrast medium, emergency drugs, and sedatives.

 Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

 Place the patient in the supine position on an exam table.

 If IV contrast medium is used, a rapid series of images is taken during and after injection.

 Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.

 Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.

 Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.

 The needle is removed, and a pressure dressing is applied over the puncture site.

 Observe the needle insertion site for bleeding, inflammation, or hematoma formation.

 **POST-TEST:**

 A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

 Instruct the patient to resume usual medications and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.

 Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

 If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

 If contrast was used, advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

 Observe the needle insertion site for bleeding, inflammation, or hematoma formation.

 Instruct the patient to apply cold compresses to the insertion site as needed, to reduce discomfort or edema.

 Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ALP, BUN, creatinine, MRI bone, bone scan, radiography of the bones.
- Refer to the Musculoskeletal System table at the back of the book for related tests by body system.

---

**Computed Tomography, Spleen**

**SYNONYM/ACRONYM:** Computed axial tomography (CAT), computed transaxial tomography (CTT), splenic CT, helical/spiral CT.

**AREA OF APPLICATION:** Abdomen/spleen.

**CONTRAST:** With or without oral or IV iodinated contrast medium.

**DESCRIPTION:** Computed tomography (CT) of the spleen is a noninvasive procedure that enhances certain anatomic views of the splenic structures. It becomes an invasive procedure with the use of contrast medium. The spleen is not often the organ of interest when abdominal CT scans are obtained. However, a wide variety of splenic variations and abnormalities may be detected on abdominal scans designed to evaluate the liver, pancreas, or retroperitoneum. During the procedure the patient lies on a table and is moved in and out of a doughnut-like device called a gantry, which houses the x-ray tube and associated electronics. The scanner uses multiple x-ray beams and a series of detectors that rotate around the patient to produce cross-sectional views in a three-dimensional fashion. Differences in tissue density are detected and recorded, and are viewable as computerized digital images. Slices or thin sections of certain anatomic views of the spleen and associated vascular system are reviewed to allow differentiation of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected hematomas and aneurysms. The procedure is repeated after IV injection of iodinated contrast medium for vascular evaluation or after oral ingestion of contrast medium for evaluation of bowel and adjacent structures. Images can be recorded on photographic or x-ray film or stored in digital format as digitized computer data. Cine scanning produces a series of moving images of the scanned area. The CT scan can be used to guide biopsy needles into areas of splenic masses to obtain tissue for laboratory analysis and for...
placement of needles to aspirate cysts or abscesses. CT scanning can monitor mass, cyst, or tumor growth and post-therapy response.

**INDICATIONS:**
- Assist in differentiating between benign and malignant tumors
- Detect tumor extension of masses and metastasis
- Differentiate infectious from inflammatory processes
- Evaluate cysts, masses, abscesses, and trauma
- Evaluate the presence of an accessory spleen, polysplenia, or asplenia
- Evaluate splenic vein thrombosis
- Monitor and evaluate effectiveness of medical, radiation, or surgical therapies

**RESULT:**

**Normal findings in:**
- Normal size, position, and shape of the spleen and associated vascular system

**Abnormal findings in:**
- Abdominal aortic aneurysm
- Hematomas
- Hemoperitoneum
- Primary and metastatic neoplasms
- Splenic cysts or abscesses
- Splenic laceration, tumor, infiltration, and trauma

**CRITICAL VALUES:**
- Abcess
- Hemorrhage
- Laceration

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

**INTERFERING FACTORS:**

This procedure is **contraindicated for:**
- Patients with allergies to shellfish or iodinated dye.
- The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients who are claustrophobic.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.
- Young patients (17 y.o. and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.

**Factors that may impair clear imaging:**
- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Patients who are very obese, or who may exceed the weight limit for the equipment
- Patients with extreme claustrophobia unless sedation is given before the study
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

**Other considerations:**
- Complications of the procedure include hemorrhage, infection at the IV needle insertion site, and cardiac arrhythmias.
The procedure may be terminated if chest pain or severe cardiac arrhythmias occur. Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated. Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the scanning room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the abdomen and spleen.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
- Obtain a history of the patient’s GI, hepatobiliary and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.
- If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.
- Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually contrast medium and normal saline are infused.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- The patient may be requested to drink approximately 450 mL of a dilute barium solution (approximately 1% barium) beginning 1 hr before the examination. This is administered to distinguish GI organs from the other abdominal organs.
- Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- The patient should fast and restrict fluids for 2 to 4 hr prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from
facility to facility. Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**
- Ensure the patient has complied with dietary, fluids, and medication restrictions for 2 to 4 hr prior to the procedure.
- Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.

Computed Tomography, Thoracic

SYNONYM/ACRONYM: Computed axial tomography (CAT), computed transaxial tomography (CTT), chest CT, helical/spiral CT.

AREA OF APPLICATION: Thorax.

CONTRAST: With or without oral or IV iodinated contrast medium.

DESCRIPTION: Computed tomography (CT) of the thorax is more detailed than a chest x-ray. It is a noninvasive procedure used to enhance certain anatomic views of the lungs, heart, and mediastinal structures. It becomes invasive when a contrast medium is used. During the procedure, the patient lies on a table and is moved in and out of a doughnut-like device called a gantry, which houses the x-ray tube and associated electronics. The scanner uses multiple x-ray beams and a series of detectors that rotate around the patient to produce cross-sectional views in a three-dimensional fashion. Differences in tissue density are detected and recorded, and are viewable as computerized digital images. Slices or thin sections of certain anatomic views of the spine, spinal cord, and lung areas are reviewed to allow differentiations of solid, cystic, inflammatory, or vascular lesions. Images can be recorded on photographic or x-ray film or stored in digital format as digitized computer data. Cine scanning is used to produce moving images of the heart.

INDICATIONS:
- Detect aortic aneurysms
- Detect bronchial abnormalities, such as stenosis, dilation, or tumor
- Detect lymphomas, especially Hodgkin’s disease
- Detect mediastinal and hilar lymphadenopathy
- Detect primary and metastatic pulmonary, esophageal, or mediastinal tumors
- Detect tumor extension of neck mass to thoracic area
- Determine blood, fluid, or fat accumulation in tissues, pleuritic space, or vessels
- Differentiate aortic aneurysms from tumors near the aorta
- Differentiate between benign and malignant tumors
- Differentiate infectious from inflammatory processes

RELATED MONOGRAPHS:
- Related tests include angiography abdomen, BUN, creatinine, KUB film, MRI abdomen, and US liver.
- Refer to the Gastrointestinal, Hepatobiliary, and Genitourinary System tables at the back of the book for related tests by body system.
• Differentiate tumor from tuberculosis
• Evaluate cardiac chambers and pulmonary vessels
• Evaluate the presence of plaque in cardiac vessels
• Monitor and evaluate effectiveness of medical or surgical therapeutic regimen

RESULT:

Normal findings in:
• Normal size, position, and shape of thoracic organs, tissues, and structures

Abnormal findings in:
• Aortic aneurysm
• Chest, mediastinal, spine, or rib lesions
• Cysts or abscesses
• Enlarged lymph nodes
• Esophageal pathology, including tumors
• Hodgkin’s disease
• Pleural effusion
• Pneumonitis
• Pneumothorax
• Pulmonary embolism

CRITICAL VALUES:
• Aortic aneurysm
• Aortic dissection
• Pneumothorax
• Pulmonary embolism

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
• Patients who are claustrophobic.

This procedure may be terminated if chest pain or severe cardiac arrhythmias occur.

Factors that may impair clear imaging:
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
• Patients who are very obese, or who may exceed the weight limit for the equipment
• Patients with extreme claustrophobia unless sedation is given before the study
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
• Complications of the procedure may include hemorrhage, infection at the IV needle insertion site, and cardiac arrhythmias.
• Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the scanning room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the chest.
- Obtain a history of the patient’s complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
- Obtain a history of the patient’s respiratory system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.
- If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.
- Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually contrast medium and normal saline are infused.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- The patient should fast and restrict fluids for 2 to 4 hr prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility.
- **INTRATEST:**
- Ensure the patient has complied with dietary, fluid, and medication restrictions for 2 to 4 hr prior to the procedure.
- Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the...
procedure. Use nonionic contrast medium for the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Establish an IV fluid line for the injection of contrast medium, emergency drugs, and sedatives.

Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

Place the patient in the supine position on an exam table.

If IV contrast medium is used, a rapid series of images is taken during and after injection.

Ask the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.

Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.

The needle is removed, and a pressure dressing is applied over the puncture site.

Observe the needle insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual medications and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

If contrast was used, advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

Observe the needle site for bleeding, inflammation, or hematoma formation.

Instruct the patient to apply cold compresses to the insertion site as needed, to reduce discomfort or edema.

Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.

Inform the patient that diarrhea may occur after ingestion of oral contrast medium.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include biopsy bone marrow, BUN, chest x-ray, complete blood count, creatinine, echocardiogram, gallium scan, lung scan, MRI chest, mediastinoscopy, and pleural fluid analysis.

Refer to the Respiratory System table at the back of the book for related tests by body system.
Coombs’ Antiglobulin, Direct

SYNONYM/ACRONYM: Direct antiglobulin testing (DAT).

SPECIMEN: Serum (1 mL) collected in a red-top tube and whole blood (1 mL) collected in lavender-top (EDTA) tube.

REFERENCE VALUE: (Method: Agglutination) Negative (no agglutination).

DESCRIPTION: Direct antiglobulin testing (DAT) detects in-vivo antibody sensitization of red blood cells (RBCs). Immunoglobulin G (IgG) produced in certain disease states or in response to certain drugs can coat the surface of RBCs, resulting in cellular damage and hemolysis. When DAT is performed, RBCs are taken from the patient’s blood sample, washed with saline to remove residual globulins, and mixed with anti-human globulin reagent. If the anti-human globulin reagent causes agglutination of the patient’s RBCs, specific antiglobulin reagents can be used to determine whether the patient’s RBCs are coated with IgG, complement, or both. (See monograph titled “Blood Groups and Antibodies,” and Appendix D for more information regarding transfusion reactions.)

INDICATIONS:
- Detect autoimmune hemolytic anemia or hemolytic disease of the newborn
- Evaluate suspected drug-induced hemolytic anemia
- Evaluate transfusion reaction

RESULT:
Positive findings in:
- Antibodies formed during these circumstances or conditions

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs and substances that may cause a positive DAT include acetaminophen, aminopyrine, aminosalicylic acid, ampicillin, antihistamines, aztreonam, cephalosporins, chlorinated hydrocarbon insecticides, chlorpromazine, chlorpropamide, cisplatin, clonidine, dipyrene, ethosuximide, fenfluramine, hydralazine, hydrochlorothiazide, ibuprofen, insulin, isoniazid, levodopa, mefenamic acid, melphalan, methadone, methicillin, methylprednisolone, moxalactam, penicillin, phenytoin, probenecid,

access additional resources at davisplus.fadavis.com
procainamide, quinidine, quinine, rifampin, stibophen, streptomycin, sulfonamides, and tetracycline.
• Wharton’s jelly may cause a false-positive DAT.
• Cold agglutinins and large amounts of paraproteins in the specimen may cause false-positive results.
• Newborns’ cells may give negative results in ABO hemolytic disease.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to detect associated conditions or drug therapies that can result in cell hemolysis.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic system as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture. If a cord sample is to be taken from a newborn, inform parents that the sample will be obtained at the time of delivery and will not result in blood loss to the infant.
- **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Note positive test results in cord blood of neonate; also assess newborn’s bilirubin and hematocrit levels. Results may indicate the need for immediate exchange transfusion of fresh whole blood that has been typed and cross-matched with the mother’s serum.
- Inform the postpartum patient of the implications of positive test results in cord blood. Prepare the newborn for exchange transfusion, on medical direction.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.
**Indirect Antiglobulin Test (IAT), Antibody Screen**

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Agglutination) Negative (no agglutination).

**DESCRIPTION:** The indirect antiglobulin test (IAT) detects and identifies unexpected circulating complement molecules or antibodies in the patient’s serum. The first use of this test was for the detection and identification of anti-D using an indirect method. The test is now commonly used to screen a patient’s serum for the presence of antibodies that may react against transfused red blood cells (RBCs). During testing, the patient’s serum is allowed to incubate with reagent RBCs. The reagent RBCs used are from group O donors and have most of the clinically significant antigens present (D, C, E, c, e, K, M, N, S, s, Fy^a, Fy^b, Jk^a, and Jk^b). Antibodies present in the patient’s serum coat antigenic sites on the RBC membrane. The reagent cells are washed with saline to remove any unbound antibody. Antihuman globulin is added in the final step of the test. If the patient’s serum contains antibodies, the antihuman globulin will cause the antibody-coated RBCs to stick together or agglutinate. (See monograph titled “Blood Groups and Antibodies,” and Appendix D for more information regarding transfusion reactions.)

**INDICATIONS:**
- Detect other antibodies in maternal blood that can be potentially harmful to the fetus
- Determine antibody titers in Rh-negative women sensitized by an Rh-positive fetus
- Screen for antibodies before blood transfusions
- Test for the weak Rh-variant antigen D_u.

**RESULT:**

**Positive findings in:**
- Circulating antibodies or medications attach to the patient’s RBCs and hemolysis occurs.
- Hemolytic anemia (Drug-induced or autoimmune)
- Hemolytic disease of the newborn
- Incompatible crossmatch
- Maternal-fetal Rh incompatibility

**Negative findings in:**
- Samples in which the patient’s antibodies exhibit dosage effects (i.e., stronger reaction with homozygous than with heterozygous expression of an antigen) and reagent erythrocyte antigens contain single-dose expressions of the corresponding antigen (heterozygous)

Access additional resources at davisplus.fadavis.com
• Samples in which reagent erythrocyte antigens are unable to detect low-prevalence antibodies
• Samples in which sensitization of erythrocytes has not occurred (complete absence of antibodies)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may cause a positive IAT include penicillin, phenacetin, quinidine, and rifampin.
• Recent administration of dextran, whole blood or fractions, or IV contrast media can result in a false-positive reaction.

INTRATEST:
• If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
• Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
• Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
• Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
• Promptly transport the specimen to the laboratory for processing and analysis.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
Inform the patient that the test is used to check donor and recipient blood cells for antibodies prior to blood transfusion.
Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
Obtain a history of the patient’s hematopoietic system as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
Note any recent procedures that can interfere with test results.
Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
Review the procedure with the patient.
Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
There are no food, fluid, or medication restrictions unless by medical direction.

POST-TEST:
A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
Inform pregnant women that negative tests during the first 12 wk of gestation should be repeated at 28 wk to rule out the presence of an antibody.
Positive test results in pregnant women after 28 wk of gestation indicate the need for antibody identification testing.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
Related tests include bilirubin, blood groups and antibodies, Coombs’ direct antiglobulin (DAT), haptoglobin, complete blood count, hematocrit, and complete blood count, hemoglobin.
Refer to the Hematopoietic System table at the back of the book for related tests by body system.
Copper

**SYNONYM/ACRONYM:** Cu.

**SPECIMEN:** Serum (1 mL) collected in a royal blue-top, trace element–free tube.

**REFERENCE VALUE:** (Method: Atomic absorption spectrophotometry)

Values for African Americans are 8% to 12% higher.

**DESCRIPTION:** Copper is an important cofactor for the enzymes that participate in the formation of hemoglobin and collagen. Copper is also a component of coagulation factor V and assists in the oxidation of glucose. It is required for melanin pigment formation and maintenance of myelin sheaths and is used to synthesize ceruloplasmin. Copper levels vary with intake. Levels vary diurnally and peak during morning hours. This mineral is absorbed in the stomach and duodenum, stored in the liver, and excreted in urine and in feces with bile salts. Copper deficiency results in neutropenia and a hypochromic, microcytic anemia that is not responsive to iron therapy. Other signs and symptoms of copper deficiency include osteoporosis, depigmentation of skin and hair, impaired immune system response, and possible neurologic and cardiac abnormalities.

**INDICATIONS:**
- Assist in establishing a diagnosis of Menkes disease
- Assist in establishing a diagnosis of Wilson’s disease
- Monitor patients receiving long-term parenteral nutrition therapy

**RESULT:**

*Increased in:*

Ceruloplasmin is an acute phase reactant protein and the main protein binder of copper; therefore copper levels will be increased in many inflammatory conditions including cancer.

Access additional resources at davisplus.fadavis.com
Nursing Implications and Procedure

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to monitor exposure to copper.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic, hepatobiliary, and immune systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase copper levels include anticonvulsants and oral contraceptives.
- Drugs that may decrease copper levels include citrates, penicillamine, and valproic acid.
- Excessive therapeutic intake of zinc may interfere with intestinal absorption of copper.

**ANEMIAS (Response to increased RBC production)**
- Ankylosing rheumatoid spondylitis
- Biliary cirrhosis (Release from damaged liver tissue)
- Collagen diseases
- Complications of renal dialysis
- Hodgkin’s disease
- Infections
- Inflammation
- Leukemia
- Malignant neoplasms
- Myocardial infarction (Toxicity can cause heart problems)
- Pellagra
- Poisoning from copper-contaminated solutions or insecticides
- Pregnancy (Estrogen increases copper levels)
- Pulmonary tuberculosis
- Rheumatic fever
- Rheumatoid arthritis
- Systemic lupus erythematosus
- Thalassemias
- Thyroid disease (hypothyroid or hyperthyroid)
- Trauma
- Typhoid fever
- Use of copper intrauterine device

**DECREASED IN:**
- Burns (Related to loss of stores in tissue and possibly to competitive inhibition of zinc containing medications or vitamins administered as part of burn therapy)
- Cystic fibrosis
- Dysproteinemia (Affects transport to and from stores)
- Infants (especially premature infants) receiving milk deficient in copper
- Iron-deficiency anemias (some) (Copper promotes absorption of iron from the intestines and transfer from tissues to plasma; it is essential to hemoglobin formation)
- Long-term total parenteral nutrition (Inadequate intake)
- Malabsorption disorders (celiac disease, tropical sprue) (Inadequate absorption)
- Malnutrition (Inadequate intake)
- Menkes disease (Severe X-linked defect causing failed transport to the liver and tissues)
- Nephrotic syndrome (Loss of transport proteins)
- Occipital hom syndrome (OHS) (Inherited disorder of copper metabolism; similar to Menkes)
- Wilson’s disease (Genetic defect causing failed transport to the liver and tissues)
Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- **Nutritional considerations:** Instruct the patient with increased copper levels to avoid foods rich in copper and to increase intake of elements (zinc, iron, calcium, and manganese) that interfere with copper absorption, as appropriate. Copper deficiency does not normally occur in adults, but patients receiving long-term total parenteral nutrition should be evaluated if signs and symptoms of copper deficiency appear. These patients should be informed that organ meats, shellfish, nuts, and legumes are good sources of dietary copper.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include biopsy liver, ceruloplasmin, complete blood count, and zinc.
- Refer to the Hematopoietic, Hepatobiliary, and Immune System tables at the end of the book for related tests by body system.

**SYNONYM/ACRONYM:** Hydrocortisone, compound F.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable. Care must be taken to use the same type of collection container if serial measurements are to be taken.

Access additional resources at davisplus.fadavis.com
### ACTH Challenge Tests

**CRH stimulation**
- 2–4 fold increase over baseline ACTH or cortisol level

**Dexamethasone Suppressed**
- Cortisol less than 3 mcg/dL next day

**ACTH (Cosyntropin) Stimulated, Rapid Test**
- Cortisol greater than 20 mcg/dL

**Metyrapone Stimulated**
- ACTH greater than 75 pg/mL
- Cortisol less than 3 mcg/dL next day

### Reference Value

**Cortisol**

**ACTH Challenge Tests**
- 2–4 fold increase over baseline ACTH or cortisol level

**Dexamethasone Suppressed**
- Cortisol less than 3 mcg/dL next day

**ACTH (Cosyntropin) Stimulated, Rapid Test**
- Cortisol greater than 20 mcg/dL

**Metyrapone Stimulated**
- ACTH greater than 75 pg/mL
- Cortisol less than 3 mcg/dL next day

### ACTH = adrenocorticotropic hormone; CRH = corticotropin-releasing hormone.

### Description:
Cortisol (hydrocortisone) is the predominant glucocorticoid secreted in response to stimulation by the hypothalamus and pituitary adrenocorticotropic hormone (ACTH). Cortisol

---

**ACTH** = adrenocorticotropic hormone; **CRH** = corticotropin-releasing hormone; **IM** = intramuscular; **IV** = intravenous.

**REFERENCE VALUE:** (Method: Immunoassay)
The corticotropin-releasing hormone (CRH) stimulation test works as well as the dexamethasone suppression test in distinguishing Cushing’s disease from conditions in which ACTH is secreted ectopically. In this test, cortisol levels are measured after an injection of CRH. A fourfold increase in cortisol levels above baseline is seen in Cushing’s disease. No increase in cortisol is seen if ectopic ACTH secretion is the cause.

The ACTH (cosyntropin) stimulated, rapid test is used when adrenal insufficiency is suspected. Cosyntropin is a synthetic form of ACTH. A baseline cortisol level is collected before the injection of cosyntropin. Specimens are subsequently collected at 30- and 60-min intervals. If the adrenal glands are functioning normally, cortisol levels rise significantly after administration of cosyntropin.

The metyrapone stimulation test is used to distinguish corticotropin-dependent (pituitary Cushing’s disease and ectopic Cushing’s disease) from corticotropin-independent (carcinoma of the lung or thyroid) causes of increased cortisol levels. Metyrapone inhibits the conversion of 11-deoxycortisol to cortisol. Cortisol levels should decrease to less than 3 mcg/dL if normal pituitary stimulation by ACTH occurs after an oral dose of metyrapone. Specimen collection and administration of the medication are performed as with the overnight dexamethasone test.

Increased in:
Conditions that result in excessive production of cortisol.
- Adrenal adenoma
- Cushing’s syndrome
- Ectopic ACTH production
- Hyperglycemia
- Pregnancy
- Stress

INDICATIONS:
- Detect adrenal hyperfunction (Cushing’s syndrome)
- Detect adrenal hypofunction (Addison’s disease)

RESULT: The dexamethasone suppression test is useful in differentiating the causes for increased cortisol levels. Dexamethasone is a synthetic steroid that suppresses secretion of ACTH. With this test, a baseline morning cortisol level is collected, and the patient is given a 1-mg dose of dexamethasone at bedtime. A second specimen is collected the following morning. If cortisol levels have not been suppressed, adrenal adenoma may be suspected. The dexamethasone suppression test also produces abnormal results in patients with psychiatric illnesses.

stimulates gluconeogenesis, mobilizes fats and proteins, antagonizes insulin, and suppresses inflammation. Measuring levels of cortisol in blood is the best indicator of adrenal function. Cortisol secretion varies diurnally, with highest levels occurring on awakening and lowest levels occurring late in the day. Bursts of cortisol excretion can occur at night. Cortisol and ACTH test results are evaluated together because they each control the other’s concentrations (i.e., any change in one causes a change in the other). ACTH levels exhibit a diurnal variation, peaking between 6 and 8 a.m. and reaching the lowest point between 6 and 11 p.m. Evening levels are generally one-half to two-thirds lower than morning levels. (See monograph titled “Adrenocorticotropic Hormone [and Challenge Tests].”)
Decreased in:
Conditions that result in adrenal hypofunction and corresponding low levels of cortisol.

- Addison's disease
- Adrenogenital syndrome
- Hypopituitarism

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs and substances that may increase cortisol levels include amphetamines, anticonvulsants, clomipramine, corticotropin, cortisone, CRH, cyclic AMP, ether, fenfluramine, hydrocortisone, insulin, lithium, methadone, metoclopramide, naloxone, opiates, oral contraceptives, prednisolone, ranitidine, spironolactone, tetracosactrin, and vasopressin.
- Drugs and substances that may decrease cortisol levels include barbiturates, beclomethasone, betamethasone, clonidine, danazol, desoximetasone, desoxycorticosterone, dexamethasone, ephedrine, etomidate, fluocinolone, ketoconazole, levodopa, lithium, methylprednisolone, metyrapone, midazolam, morphine, nitrous oxide, oxazepam, phenytoin, ranitidine, and trimipramine.
- Test results are affected by the time this test is done because cortisol levels vary diurnally.
- Stress and excessive physical activity can produce elevated levels.
- Normal values can be obtained in the presence of partial pituitary deficiency.
- Recent radioactive scans within 1 wk of the test can interfere with test results.
- The metyrapone stimulation test is contraindicated in patients with suspected adrenal insufficiency.
- Metyrapone may cause gastrointestinal distress and/or confusion. Administer oral dose of metyrapone with milk and snack.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of adrenocortical insufficiency.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that multiple specimens may be required. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.
- Drugs that enhance steroid metabolism may be withheld by medical direction prior to metyrapone stimulation testing.
- Instruct the patient to minimize stress to avoid raising cortisol levels.

INTRATEST:
- Have emergency equipment readily available.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Collect specimen between 6 and 8 a.m., when cortisol levels are highest. Perform a venipuncture.

Adverse reactions to metyrapone include nausea and vomiting (N/V), abdominal pain, headache, dizziness, sedation, allergic rash, decreased white blood cell count, or bone marrow depression. Signs and symptoms of overdose or acute adrenocortical insufficiency include cardiac arrhythmias, hypotension, dehydration, anxiety, confusion, weakness, impairment of consciousness, N/V, epigastric pain, diarrhea, hyponatremia, and hyperkalemia.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage. Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume usual medications, as directed by the HCP.

**RELATED MONOGRAPHS:**
- Related tests include ACTH and challenge tests, angiography adrenal, chloride, CT abdomen, CT pituitary, DHEA, glucagon, glucose, glucose tolerance test, growth hormone, insulin, MRI abdomen, MRI pituitary, renin, sodium, and testosterone.
- Refer to the Endocrine System table at the back of the book for related tests by body system.

**C-Peptide**

**SYNONYM/ACRONYM:** Connecting peptide insulin, insulin C-peptide, proinsulin C-peptide.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Immunochemiluminometric assay, ICMA)

<table>
<thead>
<tr>
<th>Conventional Units</th>
<th>SI Units (Conventional Units × 0.333)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.78–1.8 ng/mL</td>
<td>0.26–0.63 nmol/L</td>
</tr>
</tbody>
</table>
DESCRIPTION: C-peptide is a biologically inactive peptide formed when beta cells of the pancreas convert proinsulin to insulin. Most of C-peptide is secreted by the kidneys. C-peptide levels usually correlate with insulin levels and provide a reliable indication of how well the beta cells secrete insulin. Release of C-peptide is not affected by exogenous insulin administration. C-peptide values double after stimulation with glucose or glucagon. An insulin/C-peptide ratio less than 1.0 indicates endogenous insulin secretion, whereas a ratio of greater than 1.0 indicates an excess of exogenous insulin.

INDICATIONS:
• Assist in the diagnosis of insulinoma: Serum levels of insulin and C-peptide are elevated.
• Detect suspected factitious cause of hypoglycemia (excessive insulin administration): an increase in blood insulin from injection does not increase C-peptide levels.
• Determine beta cell function when insulin antibodies preclude accurate measurement of serum insulin production.
• Distinguish between insulin-dependent (type 1) and non–insulin-dependent (type 2) diabetes (with C-peptide–stimulating test): Patients with diabetes whose C-peptide stimulation level is greater than 18 ng/mL can be managed without insulin treatment.
• Evaluate hypoglycemia.

RESULT:

Increased in:
• Islet cell tumor (Excessive endogenous insulin production)
• Non–insulin-dependent (type 2) diabetes (Related to increased insulin production)
• Pancreas or beta cell transplants (Related to increased insulin production)
• Renal failure (Increase in circulating levels of C-peptide related to decreased excretion)

Decreased in:
• Factitious hypoglycemia (Pancreas does not produce insulin in response to increased blood insulin levels from insulin injection)
• Insulin-dependent (type 1) diabetes (Pancreas is not producing insulin)
• Pancreatectomy (Pancreas is absent)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may increase C-peptide levels include betamethasone, chloroquine, danazol, deferoxamine, ethinyl estradiol, oral contraceptives, prednisone, and rifampin.
• Drugs that may decrease C-peptide levels include atenolol and calcitonin.
• C-peptide and endogenous insulin levels do not always correlate in obese patients.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is primarily used in the evaluation of hypoglycemia.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

The patient should fast for at least 10 hr before specimen collection. Protocols may vary from facility to facility.

There are no fluid or medication restrictions unless by medical direction.

**INTRATEST:**

- Ensure that the patient has complied with dietary restrictions and pretesting preparations; assure that food has been restricted for at least 10 hr prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume usual diet as directed by the HCP.
- **Nutritional considerations:** Abnormal C-peptide levels may be associated with diabetes. Instruct the diabetic patient, as appropriate, in nutritional management of the disease. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. There is no “diabetic diet”; however, there are many meal-planning approaches with nutritional goals endorsed by the American Dietetic Association. The nutritional requirements of each diabetic patient need to be determined individually with the appropriate health care professionals, particularly health care workers trained in nutrition.
- Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy). Emphasize, as appropriate, that good control of glucose levels delays the onset and slows the progression of diabetic retinopathy, nephropathy, and neuropathy.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Diabetes Association (www.diabetes.org).
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include CT cardiac scoring, cortisol, creatinine, creatinine clearance, EMG, ENG, fluorescein angiography, fructose, fundus photography, glucagon, glucose, glucose tolerance tests, glycated hemoglobin, insulin, insulin antibodies, microalbumin, plethysmography, and visual fields test.
- Refer to the Endocrine System table at the end of the book for related tests by body system.
C-Reactive Protein

SYNONYM/ACRONYM: CRP.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: High-sensitivity immunoassay, nephelometry)

> High-sensitivity immunoassay (cardiac applications) 1.0–3.0 mg/L

INDICATIONS:
- Assist in the differential diagnosis of appendicitis and acute pelvic inflammatory disease
- Assist in the differential diagnosis of Crohn’s disease and ulcerative colitis
- Assist in the differential diagnosis of rheumatoid arthritis and uncomplicated systemic lupus erythematosus (SLE)
- Assist in the evaluation of coronary artery disease
- Detect the presence or exacerbation of inflammatory processes
- Monitor response to therapy for autoimmune disorders such as rheumatoid arthritis

RESULT:
Increased in:
Conditions associated with an inflammatory response stimulate production of CRP.
- Acute bacterial infections
- Crohn’s disease
- Inflammatory bowel disease
- Myocardial infarction

(Inflammation of the coronary vessels is associated with increased CRP levels and increased risk for coronary vessel injury which may result in distal vessel plaque occlusions.)

DESCRIPTION: C-reactive protein (CRP) is a glycoprotein produced by the liver in response to acute inflammation. The CRP assay is a nonspecific test that determines the presence (not the cause) of inflammation; it is often ordered in conjunction with erythrocyte sedimentation rate (ESR). CRP assay is a more sensitive and rapid indicator of the presence of an inflammatory process than ESR. CRP disappears from the serum rapidly when inflammation has subsided. The inflammatory process and its association with atherosclerosis make the presence of CRP, as detected by highly sensitive CRP assays, a potential marker for coronary artery disease. It is believed that the inflammatory process may instigate the conversion of a stable plaque to a weaker one that can rupture and occlude an artery.
C-REACTIVE PROTEIN

- Pregnancy (second half)
- Rheumatic fever
- Rheumatoid arthritis
- SLE
- Syndrome X (metabolic syndrome) *(Inflammation of the coronary vessels is associated with increased CRP levels and increased risk for coronary vessel injury which may result in distal vessel plaque occlusions.)*

**Decreased in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may decrease CRP levels include aurothiomalate, methotrexate, NSAIDs, oral contraceptives (progestogen effect), penicillamine, pentopril, and sulfasalazine.
- NSAIDs, salicylates, and steroids may cause false-negative results because of suppression of inflammation.
- Falsely elevated levels may occur with the presence of an intrauterine device.
- Lipemic samples that are turbid in appearance may be rejected for analysis when nephelometry is the test method.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to indicate nonspecific inflammatory response; the highly sensitive CRP is used to assess risk for cardiovascular and peripheral vascular disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex. The patient may complain of pain related to the inflammatory process in connective or other tissues.
- Obtain a history of the patient’s cardiovascular and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Access additional resources at davisplus.fadavis.com
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include antiarrhythmic drugs, ANA, antibodies, anticyclic citrullinated apolipoprotein A and B, AST, arthroscopy, ANP, blood gases, BMD, bone scan, BNP, calcium (blood and ionized), cholesterol (total, HDL, and LDL), CRP, complete blood count, CT, cardiac scoring, CK and isoenzymes, echocardiography, ESR, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, MRI chest, MRI musculoskeletal, MI scan, myocardial perfusion scan, myoglobin, PET heart, potassium, radiography bone, RF, synovial fluid analysis, triglycerides, troponin, and complete blood count, WBC count and differential.
- Refer to the Cardiovascular and Immune System tables at the end of the book for related tests by body system.

---

**Creatine Kinase and Isoenzymes**

**SYNONYM/ACRONYM:** CK and isoenzymes.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Serial specimens are highly recommended. Care must be taken to use the same type of collection container if serial measurements are to be taken.

**REFERENCE VALUE:** (Method: Enzymatic for CK, electrophoresis for isoenzymes; enzyme immunoassay techniques are in common use for CK-MB)

CK = creatine kinase; CK-BB = CK isoenzyme in brain; CK-MB = CK isoenzyme in heart; CK-MM = CK isoenzyme in skeletal muscle. The CK-MB Index is the CK-MB (by immunoassay) divided by the total CK, and then multiplied by 100. For example a CK-MB by immunoassay of 25 ng/mL with a total CK of 230 units/L would have a CK-MB index of 10.9.
**DESCRIPTION:** Creatine kinase (CK) is an enzyme that exists almost exclusively in skeletal muscle, heart muscle, and, in smaller amounts, in the brain and lungs. This enzyme is important in intracellular storage and energy release. Three isoenzymes, based on primary location, have been identified by electrophoresis: brain and lungs CK-BB, cardiac CK-MB, and skeletal muscle CK-MM. When injury to these tissues occurs, the enzymes are released into the bloodstream. Levels increase and decrease in a predictable time frame. Measuring the serum levels can help determine the extent and timing of the damage. Noting the presence of the specific isoenzyme helps determine the location of the tissue damage. Atypical forms of CK can be identified. Macro-CK, an immunoglobulin complex of normal CK isoenzymes, has no clinical significance. Mitochondrial-CK is sometimes identified in the sera of seriously ill patients, especially those with metastatic carcinoma.

Acute myocardial infarction (MI) releases CK into the serum within the first 48 hr; values return to normal in about 3 days.

The isoenzyme CK-MB appears in the first 4 to 6 hr, peaks in 24 hr, and usually returns to normal in 72 hr. Recurrent elevation of CK suggests reinfarction or extension of ischemic damage. Significant elevations of CK are expected in early phases of muscular dystrophy, even before the clinical signs and symptoms appear. CK elevation diminishes as the disease progresses and muscle mass decreases. Differences in total CK with age and gender relate to the fact that the predominant isoenzyme is muscular in origin. Body builders have higher values, whereas older individuals have lower values because of deterioration of muscle mass.

Serial use of the mass assay for CK-MB with serial cardiac troponin I, myoglobin, and serial electrocardiograms in the assessment of MI has largely replaced the use of CK isoenzyme assay by electrophoresis. CK-MB mass assays are more sensitive and rapid than electrophoresis. Studies have demonstrated a high positive predictive value for acute MI when the CK-MB (by immunoassay) is greater than 10 ng/mL with a relative CK-MB index greater than 3.0.

INDICATIONS:
- Assist in the diagnosis of acute MI and evaluate cardiac ischemia (CK-MB)
- Detect musculoskeletal disorders that do not have a neurological basis, such as dermatomyositis or Duchenne’s muscular dystrophy (CK-MM)
- Determine the success of coronary artery reperfusion after streptokinase infusion or percutaneous transluminal angioplasty, as evidenced by a decrease in CK-MB

RESULT:
Increased in:
CK is released from any damaged cell in which it is stored so conditions that affect the brain, heart, or skeletal muscle and cause cellular destruction demonstrate elevated CK levels and correlating isoenzyme source CK-BB, CK-MB, CK-MM.
- Alcoholism (CK-MM)
- Brain infarction (extensive) (CK-BB)
- Congestive heart failure (CK-MB)
- Delirium tremens (CK-MM)
- Dermatomyositis (CK-MM)
- Head injury (CK-BB)
- Hypothyroidism (CK-MM related to metabolic effect on skeletal muscle tissue)
- Hypoxic shock (CK-MM related to muscle damage from lack of oxygen)
- Gastrointestinal (GI) tract infarction (CK-MM)
- Loss of blood supply to any muscle (CK-MM)
- Malignant hyperthermia (CK-MM related to skeletal muscle injury)
- MI (CK-MB)
- Muscular dystrophies (CK-MM)
- Myocarditis (CK-MM)
- Neoplasms of the prostate, bladder, and GI tract (CK-MM)
- Polymyositis (CK-MM)
- Pregnancy; during labor (CK-MM)
- Prolonged hypothermia (CK-MM)
- Pulmonary edema (CK-MM)
- Pulmonary embolism (CK-MM)
- Reye’s syndrome (CK-BB)
- Rhabdomyolysis (CK-MM)
- Surgery (CK-MM)
- Tachycardia (CK-MB)
- Tetanus (CK-MM related to muscle injury from injection)
- Trauma (CK-MM)

Decreased in:
- Small stature (Related to lower muscle mass than average stature)
- Sedentary lifestyle (Related to decreased muscle mass)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs that may increase total CK levels include any intramuscularly injected preparations because of tissue trauma caused by injection.
- Drugs that may decrease total CK levels include dantrolene and statins.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is primarily used to assist in monitoring MI and some disorders of the musculoskeletal system.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs.
CREATINE KINASE AND ISOENZYMES

Access additional resources at davisplus.fadavis.com

nutritional supplements, and nutraceuticals.
 Review the procedure with the patient. Inform the patient that a series of samples will be required. (Samples at time of admission and 2 to 4 hr, 6 to 8 hr, and 12 hr after admission are the minimal recommendations. Protocols may vary from facility to facility. Additional samples may be requested.) Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:
 If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
 Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
 Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
 Remove the needle, and apply a pressure dressing over the puncture site.
 Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
 A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
 Nutritional considerations: Increased CK levels may be associated with coronary artery disease (CAD). Nutritional therapy is recommended for individuals identified to be at high risk for developing CAD. If overweight, the patient should be encouraged to achieve a normal weight. The American Heart Association Step 1 and Step 2 diets may be helpful in achieving a goal of lowering total cholesterol and triglyceride levels. The Step 1 diet emphasizes a reduction in foods high in saturated fats and cholesterol. Red meats, eggs, and dairy products are the major sources of saturated fats and cholesterol. If triglycerides are also elevated, the patient should be advised to eliminate or reduce alcohol and simple carbohydrates from the diet. The Step 2 diet recommends stricter reductions.
 Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org).
 Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
 Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
 Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, ANP, blood gases, BNP, calcium (blood and ionized), cholesterol (total, HDL and LDL), CRP, CT cardiac scoring, echocardiography, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI chest, MI scan, myocardial perfusion scan, myoglobin, pericardial fluid, PET heart, potassium, triglycerides, and troponin.
 Refer to the Cardiovascular and Musculoskeletal System tables at the end of the book for related tests by body system.
Creatinine, Blood

National Kidney Foundation recommends the use of 2 decimal places in reporting serum creatinine for use in calculating eGFR.

DESCRIPTION: Creatinine is the end product of creatine metabolism. Creatine resides almost exclusively in skeletal muscle, where it participates in energy-requiring metabolic reactions. In these processes, a small amount of creatine is irreversibly converted to creatinine, which then circulates to the kidneys and is excreted. The amount of creatinine generated in an individual is proportional to the mass of skeletal muscle present and remains fairly constant, unless there is massive muscle damage resulting from crushing injury or degenerative muscle disease. Creatinine values also decrease with age owing to diminishing muscle mass. Blood urea nitrogen (BUN) is often ordered with creatinine for comparison. The BUN/creatinine ratio is also a useful indicator of disease. The ratio should be between 10:1 and 20:1. Creatinine is the ideal substance for determining renal clearance because a fairly constant quantity is produced within the body. The creatinine clearance test measures a blood sample and a urine sample to determine the rate at which the kidneys are clearing creatinine from the blood; this reflects the glomerular filtration rate (see monograph titled “Creatinine, Urine, and Creatinine Clearance, Urine”).

Chronic kidney disease (CKD) is a significant health concern worldwide. An international effort to standardize methods to identify and monitor CKD has been undertaken by the National Kidney Disease Education Program (NKDEP), the International Confederation of Clinical Chemistry and Laboratory Medicine, and the European Communities Confederation of Clinical Chemistry. International efforts...
have resulted in development of an Isotope Dilution Mass Spectrometry (IDMS) reference method for standardized measurement of creatinine. The National Kidney Foundation (NKF) has recommended use of an equation to estimate glomerular filtration rate (eGFR). The equation is based on factors identified in the NKF Modification of Diet in Renal Disease (MDRD) study. The equation includes four factors: serum or plasma creatinine value, age (in years), gender, and race. The equation is valid only for patients between the ages of 18 and 70. A correction factor is incorporated in the equation if the patient is African American as CKD is more prevalent in African Americans; results are approximately 20% higher. It is very important to know whether the creatinine has been measured using an IDMS traceable test method because the values will differ; results are lower. The equations have not been validated for pregnant women, patients younger than 18 or older than 70, patients with serious comorbidities, or patients with extremes in body size, muscle mass, or nutritional status. eGFR calculators can be found at the National Kidney Disease Education Program (www.nkdep.nih.gov/professionals/gfr_calculators/index.htm).

The equation used for creatinine methods that are NOT traceable to IDMS reference method is:

• If creatinine is reported in (SI) micromol/L

\[ eGFR \, (\text{mL/min/1.73}\, \text{m}^2) = 186 \times (\text{creat/88.4})^{-1.154} \times (\text{Age})^{0.203} \times (0.742 \text{ if female}) \times (1.210 \text{ if African American}) \]

The equation used for creatinine methods that ARE traceable to IDMS reference method is:

• If creatinine is reported in mg/dL

\[ eGFR \, (\text{mL/min/1.73}\, \text{m}^2) = 175 \times (\text{creat})^{-1.154} \times (\text{Age})^{0.203} \times (0.742 \text{ if female}) \times (1.210 \text{ if African American}) \]

INDICATIONS:

• Assess a known or suspected disorder involving muscles in the absence of renal disease

• Evaluate known or suspected impairment of renal function

RESULT:

Increased in:

• Acromegaly (Related to increased muscle mass)

• Congestive heart failure (Related to decreased renal blood flow)

• Dehydration (Hemoconcentration)

• Gigantism (Related to increased muscle mass)

• Poliomyelitis (Increased release from damaged muscle)

• Renal calculi (Related to decreased renal excretion due to obstruction)

• Renal disease, acute and chronic renal failure (Related to decreased urinary excretion)
• Rhabdomyolysis *(Increased release from damaged muscle)*
• Shock *(Increased release from damaged muscle)*

**Decreased in:**
• Decreased muscle mass *owing to debilitating disease or increasing age*
• Hyperthyroidism *(Related to increased GFR)*
• Inadequate protein intake *(Related to decreased muscle mass)*
• Liver disease (severe) *(Related to fluid retention)*
• Muscular dystrophy *(Related to decreased muscle mass)*
• Pregnancy
• Small stature *(Related to decreased muscle mass)*

**CRITICAL VALUES:**
Potential critical value is greater than 7.4 mg/dL (nondialysis patient).

Note and immediately report to the health care provider (HCP) any critically increased values and related symptoms. Chronic renal insufficiency is identified by creatinine levels between 1.5 and 3.0 mg/dL; chronic renal failure is present at levels greater than 3.0 mg/dL.

Possible interventions may include renal or peritoneal dialysis and organ transplant, but early discovery of the cause of elevated creatinine levels might avoid such drastic interventions.

**INTERFERING FACTORS:**
• Drugs and substances that may increase creatinine levels include acebutolol, acetaminophen (overdose), acetylsalicylic acid, aldatense, amikacin, amiodarone, amphotericin B, arginine, arsenicals, ascorbic acid, asparaginase, barbiturates, capreomycin, captopril, carbutamide, carvedilol, cephalothin, chlorothalidone, cimetidine, cisplatin, clofibrate, colistin, corn oil (Lipomul), cyclosporine, dextran, doxycycline, enalapril, ethylene glycol, gentamicin, indomethacin, ipodate, kanamycin, levodopa, mannitol, methicillin, methoxyflurane, mitomycin, neomycin, netilmycin, nitrofurantoin, NSAIDs, oxyphenbutazone, paromomycin, penicillin, pentamidine, phosphorus, plicamycin, radiographic agents, semustine, streptokinase, streptozocin, tetracycline, thiazides, tobramycin, triamterene, vancomycin, vasopressin, viomycin, and vitamin D.
• Drugs that may decrease creatinine levels include citrates, dopamine, ibuprofen, and lisinopril.
• High blood levels of bilirubin and glucose can cause false decreases in creatinine.
• A diet high in meat can cause increased creatinine levels.
• Ketosis can cause a significant increase in creatinine.
• Hemolyzed specimens are unsuitable for analysis.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to assess kidney function.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s genitourinary and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Obtain a list of the patient’s current medications, including herbs,
CREATININE, BLOOD

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions unless by medical direction.

Instruct the patient to refrain from excessive exercise for 8 hr before the test.

INTRATEST:
- Ensure that the patient has complied with activity restrictions; assure that activity has been restricted for at least 8 hr prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle, and apply a pressure dressing over the puncture site.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual activity as directed by the HCP.

Nutritional considerations: Increased creatinine levels may be associated with kidney disease. The nutritional needs of patients with kidney disease vary widely and are in constant flux. Anorexia, nausea, and vomiting commonly occur, prompting the need for continuous nutritional monitoring for malnutrition, especially among patients receiving long-term hemodialysis therapy.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the National Kidney Foundation (www.kidney.org) or the National Kidney Disease Education Program (www.nkdep.nih.gov).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include anion gap, antibiotic drugs, ANF, BNP, biopsy muscle, blood gases, BUN, calcium, calculus kidney stone panel, CT abdomen, CT renal, CK and isoenzymes, creatinine clearance, cystoscopy, echocardiography, echocardiography transesophageal, electrolytes, EMG, ENG, glucagon, glucose, glycolated hemoglobin, insulin, IVP, KUB studies, lung perfusion scan, microalbumin, osmolality, phosphorus, renogram, retrograde ureteropyelography, TSH, thyroxine, uric acid, and UA.
- Refer to the Genitourinary and Musculoskeletal System tables at the end of the book for related tests by body system.

DESCRIPTION: Creatinine is the end product of creatine metabolism. Creatine resides almost exclusively in skeletal muscle, where it participates in energy-requiring metabolic reactions. In these processes, a small amount of creatine is irreversibly converted to creatinine, which then circulates to the kidneys and is excreted. The amount of creatinine generated in an individual is proportional to the mass of skeletal muscle present and remains fairly constant, unless there is massive muscle damage resulting from crushing injury or degenerative muscle disease. Creatinine values decrease with advancing age owing to diminishing muscle mass. Although the measurement of urine creatinine is an effective indicator of renal function, the creatinine clearance test is more precise. The creatinine clearance test measures a blood sample and a urine sample to determine the rate at which the kidneys are clearing creatinine from the blood; this reflects the glomerular filtration rate and is based on an estimate of body surface.

Chronic kidney disease (CKD) is a significant health concern worldwide. An international effort to standardize methods to identify and monitor CKD has been undertaken by the National Kidney Disease Education Program (NKDEP), the International Confederation of Clinical Chemistry and Laboratory Medicine, and the European...
Communities Confederation of Clinical Chemistry. International efforts have resulted in development of an Isotope Dilution Mass Spectrometry (IDMS) reference method for standardized measurement of creatinine. The National Kidney Foundation (NKF) has recommended use of an equation to estimate glomerular filtration rate (eGFR). The equation is based on factors identified in the NKF Modification of Diet in Renal Disease (MDRD) study. The equation includes four factors: serum or plasma creatinine value, age in years, gender, and race. The equation is valid only for patients between the ages of 18 and 70. A correction factor is incorporated in the equation if the patient is African American as CKD is more prevalent in African Americans; results are approximately 20% higher. It is very important to know whether the creatinine has been measured using an IDMS traceable test method because the values will differ; results are lower. The equations have not been validated for pregnant women, patients younger than 18 or older than 70, patients with serious comorbidities, or patients with extremes in body size, muscle mass, or nutritional status. eGFR calculators can be found at the NKDEP (www.nkdep.nih.gov/professionals/gfr_calculators/index.htm).

The equation used for creatinine methods that are NOT traceable to IDMS reference method is:

- If creatinine is reported in (SI) micromol/L

\[
eGFR (\text{mL/min/1.73 m}^2) = \frac{186}{(\text{creat}/88.4)^{1.154} \times (\text{Age})^{0.203} \times (0.742 \text{ if female}) \times (1.210 \text{ if African American})}
\]

The equation used for creatinine methods that ARE traceable to IDMS reference method is:

- If creatinine is reported in mg/dL

\[
eGFR (\text{mL/min/1.73 m}^2) = \frac{175}{(\text{creat})^{1.154} \times (\text{Age})^{0.203} \times (0.742 \text{ if female}) \times (1.210 \text{ if African American})}
\]

- If creatinine is reported in (SI) micromol/L

\[
eGFR (\text{mL/min/1.73 m}^2) = \frac{175}{(\text{creat}/88.4)^{1.154} \times (\text{Age})^{0.203} \times (0.742 \text{ if female}) \times (1.210 \text{ if African American})}
\]

**INDICATIONS:**

- Determine the extent of nephron damage in known renal disease (at least 50% of functioning nephrons must be lost before values are decreased)
- Determine renal function before administering nephrotoxic drugs
- Evaluate accuracy of a 24-hr urine collection, based on the constant level of creatinine excretion
- Evaluate glomerular function
- Monitor effectiveness of treatment in renal disease

**RESULT:**

**Increased in:**

- Acromegaly (related to increased muscle mass)
- Carnivorous diets (increased intake of creatine, which is metabolized to creatinine and excreted by the kidneys)
- Exercise (related to muscle damage; increased renal blood flow)
• Gigantism (related to increased muscle mass)

Decreased in:
Conditions that decrease GFR, impair kidney function, or reduce renal blood flow will decrease renal excretion of creatinine
• Acute or chronic glomerulonephritis
• Chronic bilateral pyelonephritis
• Leukemia
• Muscle wasting diseases (related to abnormal creatinine production; decreased production reflected in decreased excretion)
• Paralysis (related to abnormal creatinine production; decreased production reflected in decreased excretion)
• Polycystic kidney disease
• Shock
• Urinary tract obstruction (e.g., from calculi)
• Vegetarian diets (diets that exclude intake of animal muscle, the creatine source metabolized to creatinine and excreted by the kidneys)

CRITICAL VALUES:
• Degree of impairment:
  Borderline: 62.5–80 mL/min/1.73 m²
  Slight: 52–62.5 mL/min/1.73 m²
  Mild: 42–52 mL/min/1.73 m²
  Moderate: 28–42 mL/min/1.73 m²
  Marked: Less than 28 mL/min/1.73 m²
Note and immediately report to the health care provider (HCP) any critically increased values and related symptoms.

INTERFERING FACTORS:
• Drugs that may increase urine creatinine levels include ascorbic acid, cefoxitin, cephalothin, corticosteroids, fluoroxymesterone, levodopa, methandrostanolone, methotrexate, methylprednisolone, nitrofurans (including nitrofurazone), oxymetholone, phenolphthalein, and prednisone.
• Drugs that may increase urine creatinine clearance include enalapril, oral contraceptives, prednisone, and ramipril.
• Drugs that may decrease urine creatinine levels include anabolic steroids, androgens, captopril, and thiazides.
• Drugs that may decrease the urine creatinine clearance include acetylsalicylic acid, amphotericin B, carbenoxolone, chlorothalidone, cimetidine, cisplatin, cyclosporine, guanidine, ibuprofen, indomethacin, mitomycin, oxphenbutazone, paromycin, probenecid (coadministered with digoxin), and thiazides.
• Excessive ketones in urine may cause falsely decreased values.
• Failure to follow proper technique in collecting 24-hr specimen may invalidate test results.
• Failure to refrigerate specimen throughout urine collection period allows decomposition of creatinine, causing falsely decreased values.
• Consumption of large amounts of meat, excessive exercise, and stress should be avoided for 24 hr before the test. Protocols may vary from facility to facility.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE
PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to assess renal function.
• Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient's genitourinary system, symptoms,
and results of previously performed laboratory tests and diagnostic and surgical procedures.

- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain to the patient that there should be no discomfort during the urine collection procedure. Inform the patient that a blood sample for creatinine will be required on the day urine collection begins or at some point during the 24 hr collection period. (see monograph titled “Creatinine, Blood” for additional information).

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- There are no fluid or medication restrictions unless by medical direction.
- Instruct the patient to refrain from eating meat during the test. Protocols may vary from facility to facility.

**INTEST:**

- Ensure that the patient has complied with dietary and activity restrictions for 24 hr prior to the procedure; assure that ingestion of meat has been restricted during the test.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

**Random specimen (Collect in Early Morning) Clean-Catch Specimen:**

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

**Pediatric Urine Collector:**

- Put on gloves. Appropriately cleanse the genital area and allow the area to dry. Remove the covering over the adhesive strips on the collector bag and apply over the genital area. Diaper the child. When specimen is obtained, place the entire collection bag in a sterile urine container.

**Indwelling Catheter:**

- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

**Urinary Catheterization:**

- Place female patient in lithotomy position or male patient in supine position. Using sterile technique, open the straight urinary catheterization kit and perform urinary catheterization. Place the retained urine in a sterile specimen container.

**Suprapubic Aspiration:**

- Place the patient in a supine position. Cleanse the area with antiseptic and drape with sterile drapes. A needle is inserted through the skin into the bladder. A syringe attached to the needle is used to aspirate the urine sample. The
needle is then removed and a sterile dressing is applied to the site. Place the sterile sample in a sterile specimen container. Do not collect urine from the pouch from the patient with a urinary diversion (e.g., ileal conduit). Instead, perform catheterization through the stoma.

**Timed Specimen:**
Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.

Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.

If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same time the collection was begun.

At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.

Include on the collection container’s label the amount of urine, test start and stop times, and any foods or medications that can affect test results.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
Instruct the patient to resume usual diet, medications, and activity, as directed by the HCP.
Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the NKF (www.kidney.org) or the NKDEP (www.nkdep.nih.gov).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
Related tests include anion gap, antibiotic drugs, antibodies antiglomerular basement membrane, ANF, biopsy kidney, biopsy muscle, blood gases, BNP, BUN, calcium, calculus kidney stone analysis, C4, CT abdomen, CT renal, CK and isoenzymes, creatinine, culture urine, cytology urine, cystoscopy, echocardiography, echocardiography transesophageal, electrolytes, EMG, ENG, EPO, gallium scan, glucagon, glucose, haptoglobin, insulin, IVP, KUB studies, lung perfusion scan, microalbumin, osmolality, phosphorus, renogram, retrograde ureteropyelography, TSH, thyroxine, US kidney, uric acid, and UA.

Refer to the Genitourinary System table at the end of the book for related tests by body system.
**CRYoglobulin**

**SYNONYM/ACRONYM:** Cryo.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Visual observation for changes in appearance) Negative.

**DESCRIPTION:** Cryoglobulins are abnormal serum proteins that cannot be detected by protein electrophoresis. Cryoglobulins cause vascular problems because they can precipitate in the blood vessels of the fingers when exposed to cold, causing Raynaud’s phenomenon. They are usually associated with immunological disease. The laboratory procedure to detect cryoglobulins is a two-step process. The serum sample is observed for cold precipitation after 72 hr of storage at 4°C. True cryoglobulins disappear on warming to room temperature, so in the second step of the procedure, the sample is rewarmed to confirm reversibility of the reaction.

**INDICATIONS:**
- Assist in diagnosis of neoplastic diseases, acute and chronic infections, and collagen diseases
- Detect cryoglobulinemia in patients with symptoms indicating or mimicking Raynaud’s disease
- Monitor course of collagen and rheumatic disorders

**RESULT:**
- **Increased in:**
  - Type I cryoglobulin (monoclonal) Chronic lymphocytic leukemia
  - Type II cryoglobulin (mixtures of monoclonal immunoglobulin [Ig] M and polyclonal IgG)
  - Autoimmune hepatitis
  - Rheumatoid arthritis
  - Sjögren’s syndrome
  - Waldenström’s macroglobulinemia
  - Type III cryoglobulin (mixtures of polyclonal IgM and IgG)
  - Acute poststreptococcal glomerulonephritis
  - Chronic infection (especially hepatitis C)
  - Cirrhosis
  - Endocarditis
  - Infectious mononucleosis
  - Polymyalgia rheumatica
  - Rheumatoid arthritis
  - Sarcoidosis
  - Systemic lupus erythematosus

- **Decreased in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Testing the sample prematurely (before total precipitation) may yield incorrect results.
- Failure to maintain sample at normal body temperature before centrifugation can affect results.
- A recent fatty meal can increase turbidity of the blood, decreasing visibility.
Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

Related monographs include ALT, ANA, arthroscopy, AST, bilirubin, biopsy liver, bone scan, ceruloplasmin, copper, CRP, ESR, GGT, infectious mono screen, hepatitis C antibody, IgA, IgG, IgM, IFE, liver and spleen scan, prolein, protein electrophoresis, RF, synovial fluid analysis, and US liver.

Refer to the Immune System table at the end of the book for related tests by body system.
SYNONYM/ACRONYM: Acid-fast bacilli (AFB) culture and smear, tuberculosis (TB) culture and smear, *Mycobacterium* culture and smear.

SPECIMEN: Sputum (5 to 10 mL), bronchopulmonary lavage, tissue, material from fine-needle aspiration, bone marrow, cerebrospinal fluid (CSF), gastric aspiration, urine, and stool.

REFERENCE VALUE: (Method: Culture on selected media, microscopic examination of sputum by acid-fast or auramine-rhodamine fluorochrome stain) Rapid methods include: chemiluminescent-labeled DNA probes that target ribosomal RNA of the *Mycobacterium* radiometric carbon dioxide detection from 14C-labeled media, polymerase chain reaction/amplification techniques.

**Culture:** No growth
**Smear:** Negative for AFB

**DESCRIPTION:** A culture and smear test is used primarily to detect *Mycobacterium tuberculosis*, which is a tubercular bacillus. The cell wall of this mycobacterium contains complex lipids and waxes that do not take up ordinary stains. Cells that resist decolorization by acid alcohol are termed acid-fast. There are only a few groups of acid-fast bacilli (AFB); this characteristic is helpful in rapid identification so that therapy can be initiated in a timely manner. Smears may be negative 50% of the time even though the culture develops positive growth 3 to 8 wk later. AFB cultures are used to confirm positive and negative AFB smears. *M. tuberculosis* grows in culture slowly. Automated liquid culture systems, such as the Bactec and MGIT (Becton Dickinson and Company, 1 Becton Drive, Franklin Lakes, NJ, 07417), have a turnaround time of approximately 10 days. Results of tests by polymerase chain reaction culture methods are available in 24 to 72 hr.

*M. tuberculosis* is transmitted via the airborne route to the lungs. It causes areas of granulomatous inflammation, cough, fever, and hemoptysis. It can remain dormant in the lungs for long periods. The incidence of tuberculosis has increased since the late 1980s in depressed inner-city areas, among prison populations, and among HIV-positive patients. Of great concern is the increase in antibiotic-resistant strains. HIV-positive patients often become ill from concomitant infections caused by *M. tuberculosis* and *Mycobacterium avium intracellulare*. *M. avium intracellulare* is acquired via the gastrointestinal tract through ingestion of contaminated food or water. The organism’s waxy cell wall protects it from acids in the human digestive tract. Isolation of mycobacteria in the
stool does not mean the patient has tuberculosis of the intestines because mycobacteria in stool are most often present in sputum that has been swallowed.

**INDICATIONS:**
- Assist in the diagnosis of suspected pulmonary tuberculosis secondary to AIDS
- Assist in the differentiation of tuberculosis from carcinoma or bronchiectasis
- Investigate suspected pulmonary tuberculosis
- Monitor the response to treatment for pulmonary tuberculosis

**RESULT:**

**CRITICAL VALUES:**
- *Smear:* Positive for AFB
- *Culture:* Growth of pathogenic bacteria

Note and immediately report to the health care provider (HCP) positive results and related symptoms.

**INTERFERING FACTORS:**
- Specimen collection after initiation of treatment with antituberculosis drug therapy may result in inhibited or no growth of organisms.
- Contamination of the sterile container with organisms from an exogenous source may produce misleading results.
- Specimens received on a dry swab should be rejected: A dry swab indicates that the sample is unlikely to have been collected properly or unlikely to contain a representative quantity of significant organisms for proper evaluation.
- Inadequate or improper (e.g., saliva) samples should be rejected.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
Inform the patient that the test is primarily used to assist in the diagnosis of tuberculosis.
Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex. Obtain a history of the patient’s exposure to tuberculosis.
Obtain a history of the patient’s immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
Note any recent procedures that can interfere with test results.
Review the procedure with the patient. Reassure the patient that he or she will be able to breathe during the procedure if sputum specimen collection is accomplished via suction method.
Ensure that oxygen has been administered 20 to 30 min before the procedure if the specimen is to be obtained by tracheal suction. Address concerns about pain related to the procedure.
Explain to the patient that the time it takes to collect a proper specimen varies according to the level of cooperation of the patient and the specimen collection site. Emphasize that sputum and saliva are not the same. Inform the patient that multiple specimens may be required at timed intervals. Inform the patient that the culture results will not be reported for 3 to 8 wk.
Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

**Bronchoscopy:**
Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

Other than antimicrobial drugs, there are no medication restrictions, unless by medical direction.
The patient should fast and refrain from drinking liquids beginning at midnight the night before the procedure. Protocols may vary from facility to facility.

**Expectorated Specimen:**
Additional liquids the night before may assist in liquefying secretions during expectoration the following morning.
Assist the patient with oral cleaning before sample collection to reduce the amount of sample contamination by organisms that normally inhabit the mouth.
Instruct the patient not to touch the edge or inside of the container with the hands or mouth.
Other than antimicrobial drugs, there are no medication restrictions, unless by medical direction.
There are no food or fluid restrictions, unless by medical direction.

**Tracheal Suctioning:**
Assist in providing extra fluids, unless contraindicated, and proper humidification to decrease tenacious secretions. Inform the patient that increasing fluid intake before retiring on the night before the test aids in liquefying secretions and may make it easier to expectorate in the morning. Also explain that humidifying inspired air also helps expectorate in the morning.
Other than antimicrobial drugs, there are no medication restrictions, unless by medical direction.
There are no food or fluid restrictions, unless by medical direction.

**INTRATEST:**
Ensure that the patient has complied with dietary and medication restrictions; assure that food and fluids have been restricted for at least 8 hr prior to the bronchoscopy procedure.
Have patient remove dentures, contact lenses, eyeglasses, and jewelry. Notify the HCP if the patient has permanent crowns on teeth. Have the patient remove clothing and change into a gown for the procedure.
Have emergency equipment readily available. Keep resuscitation equipment on hand in case of respiratory
Avoid using morphine sulfate in patients with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Assist the patient to a comfortable position, and direct the patient to breathe normally during the beginning of the local anesthesia. Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date and time of collection, and any medication the patient is taking that may interfere with test results (e.g., antibiotics).

**Bronchoscopy:**
Record baseline vital signs.
The patient is positioned in relation to the type of anesthesia being used. If local anesthesia is used, the patient is seated and the tongue and oropharynx are sprayed and swabbed with anesthetic before the bronchoscope is inserted. For general anesthesia, the patient is placed in a supine position with the neck hyperextended. After anesthesia, the patient is kept in supine or shifted to a side-lying position and the bronchoscope is inserted. After inspection, the samples are collected from suspicious sites by bronchial brush or biopsy forceps.

**Expectorated Specimen:**
Ask the patient to sit upright, with assistance and support (e.g., with an overbed table) as needed.
Ask the patient to take two or three deep breaths and cough deeply. Any sputum raised should be expectorated directly into a sterile sputum collection container.
If the patient is unable to produce the desired amount of sputum, several strategies may be attempted. One approach is to have the patient drink two glasses of water, and then assume the position for postural drainage of the upper and middle lung segments. Effective coughing may be assisted by placing either the hands or a pillow over the diaphragmatic area and applying slight pressure.

Another approach is to place a vaporizer or other humidifying device at the bedside. After sufficient exposure to adequate humidification, postural drainage of the upper and middle lung segments may be repeated before attempting to obtain the specimen.

Other methods may include obtaining an order for an expectorant to be administered with additional water approximately 2 hr before attempting to obtain the specimen. Chest percussion and postural drainage of all lung segments may also be employed. If the patient is still unable to raise sputum, the use of an ultrasonic nebulizer (“induced sputum”) may be necessary; this is usually done by a respiratory therapist.

**Tracheal Suctioning:**
Obtain the necessary equipment, including a suction device, suction kit, and Lukens tube or in-line trap.
Position the patient with head elevated as high as tolerated.
Put on sterile gloves. Maintain the dominant hand as sterile and the non-dominant hand as clean.
Using the sterile hand, attach the suction catheter to the rubber tubing of the Lukens tube or in-line trap. Then attach the suction tubing to the male adapter of the trap with the clean hand. Lubricate the suction catheter with sterile saline.
Tell nonintubated patients to protrude the tongue and to take a deep breathe as the suction catheter is passed through the nostril. When the catheter enters the trachea, a reflex cough is stimulated; immediately advance the catheter into the trachea and apply suction. Maintain suction for approximately 10 sec, but never longer than 15 sec. Withdraw the catheter without applying suction. Separate the suction
Observe the patient for hemoptysis, difficulty breathing, cough, air hunger, excessive coughing, pain, or absent breathing sounds over the affected area. Report any symptoms to the HCP.

Evaluate the patient for symptoms indicating the development of pneumothorax, such as dyspnea, tachypnea, anxiety, decreased breathing sounds, or restlessness. A chest x-ray may be ordered to check for the presence of this complication.

Evaluate the patient for symptoms of empyema, such as fever, tachycardia, malaise, or elevated white blood cell count.

Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.

Nutritional considerations: Malnutrition is commonly seen in patients with severe respiratory disease for numerous reasons, including fatigue, lack of appetite, and gastrointestinal distress. Adequate intake of vitamins A and C are also important to prevent pulmonary infection and to decrease the extent of lung tissue damage.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient to use lozenges or gargle for throat discomfort. Inform the patient of smoking cessation programs as appropriate. The importance of following the prescribed diet should be stressed to the patient/caregiver. Educate the patient regarding access to counseling services, as appropriate. Answer any questions or address any concerns voiced by the patient or family.

Instruct the patient in the use of any ordered medications. Explain the
importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Sterile fluid or swab from affected area placed in transport media tube provided by laboratory.

**REFERENCE VALUE:** (Method: Culture aerobic and/or anaerobic on selected media; DNA probe assays (e.g., Gen-Probe) are available for identification of *Neisseria gonorrhoeae* and *Chlamydia trachomatis*. Negative: no growth of pathogens.

**DESCRIPTION:** When indicated by patient history, anal and genital cultures may be performed to isolate the organism responsible for sexually transmitted disease. Group B Streptococcus (GBS) is a significant and serious neonatal infection. CDC recommends universal GBS screening for all pregnant women at 35 to 37 wk gestation. Rapid GBS test kits can provide results within minutes on vaginal or rectal fluid swab specimens submitted in a sterile red-top tube.

**RELATED MONOGRAPHS:**

- Related tests include antibodies, anti-glomerular basement membrane, arterial/alveolar oxygen ratio, blood gases, bronchoscopy, chest x-ray, complete blood count, CT thoracic, cultures (fungal, sputum, throat, viral), cytology sputum, gallium scan, gram stain, lung perfusion scan, lung ventilation scan, MRI chest, mediastinoscopy, pleural fluid analysis, pulmonary function tests, and TB tests.

- Refer to the Immune and Respiratory System tables at the end of the book for related tests by body system.

**Ear and eye cultures are performed to isolate the organism responsible for chronic or acute infectious disease of the ear and eye.**

**Skin and soft tissue samples from infected sites must be collected carefully to avoid contamination from the surrounding normal skin flora. Skin and tissue infections may be caused by both aerobic and anaerobic organisms. Therefore, a portion of the sample should be placed in aerobic and a portion in anaerobic transport media.**
Care must be taken to use transport media that are approved by the laboratory performing the testing.

Sterile fluids can be collected from the affected site. Refer to related body fluid monographs (i.e., amniotic fluid, cerebrospinal fluid, pericardial fluid, peritoneal fluid, pleural fluid, synovial fluid) for specimen collection.

A wound culture involves collecting a specimen of exudates, drainage, or tissue so that the causative organism can be isolated and pathogens identified. Specimens can be obtained from superficial and deep wounds.

Optimally, specimens should be obtained before antibiotic use. The method used to culture and grow the organism depends on the suspected infectious organism. There are transport media specifically for bacterial agents. The laboratory will select the appropriate media for suspect organisms. The laboratory will initiate antibiotic sensitivity testing if indicated by test results. Sensitivity testing identifies the antibiotics to which organisms are susceptible to ensure an effective treatment plan.

**INDICATIONS:**

**Anal/Genital:**
- Assist in the diagnosis of sexually transmitted diseases
- Determine the cause of genital itching or purulent drainage
- Determine effective antimicrobial therapy specific to the identified pathogen
- Routine prenatal screening for vaginal and rectal GBS colonization
- Isolate and identify organisms responsible for ear pain, drainage, or changes in hearing
- Isolate and identify organisms responsible for outer-, middle-, or inner-ear infection
- Determine effective antimicrobial therapy specific to the identified pathogen
- Isolate and identify pathogenic microorganisms responsible for infection of the eye
- Determine effective antimicrobial therapy specific to identified pathogen
- Isolate and identify organisms responsible for skin eruptions, drainage, or other evidence of infection
- Determine effective antimicrobial therapy specific to the identified pathogen
- Isolate and identify organisms before surrounding tissue becomes infected
- Determine effective antimicrobial therapy specific to the identified pathogen
- Detect abscess or deep-wound infectious process
- Determine if an infectious agent is the cause of wound redness, warmth, or edema with drainage at a site
- Determine presence of infectious agents in a stage 3 and stage 4 decubitus ulcer
- Isolate and identify organisms responsible for the presence of pus or other exudate in an open wound

Access additional resources at davisplus.fadavis.com
• Determine effective antimicrobial therapy specific to the identified pathogen

RESULT:

Positive findings in:

Anal/Endocervical/Genital:
Infections or carrier states are caused by the following organisms: *Chlamydia trachomatis*, *Gardnerella vaginalis*, *N. gonorrhoeae*, toxin-producing strains of *Staphylococcus aureus*, Group B *Streptococcus*, and *Treponema pallidum*.

Ear:
Commonly identified organisms include *Escherichia coli*, *Proteus* spp., *Pseudomonas aeruginosa*, *S. aureus*, and β-hemolytic streptococci.

Eye:
Commonly identified organisms include *Chlamydia trachomatis* (transmitted to newborns from infected mothers), *Haemophilus influenzae* (transmitted to newborns from infected mothers), *H. aegyptius*, *N. gonorrhoeae* (transmitted to newborns from infected mothers), *Pseudomonas aeruginosa*, *Staphylococcus aureus*, and *Streptococcus pneumoniae*.

Skin:
Commonly identified organisms include *Bacteroides*, *Clostridium*, *Corynebacterium*, *Pseudomonas*, staphylococci, and group A streptococci.

Sterile Fluids:
Commonly identified pathogens include *Bacteroides*, *Enterococcus* spp., *E. coli*, *Pseudomonas aeruginosa*, and *Peptostreptococcus* spp.

Wound:
Aerobic and anaerobic microorganisms can be identified in wound culture specimens. Commonly identified organisms include *Clostridium perfringens*, *Klebsiella*, *Proteus*, *Pseudomonas*, *Staphylococcus aureus*, and group A streptococci.

CRITICAL VALUES:
• *Listeria* in genital cultures
• Methicillin resistant *Staphylococcus aureus* (MRSA) in skin or wound cultures

Note and immediately report to the health care provider (HCP) positive results and related symptoms.

INTERFERING FACTORS:
• Failure to collect adequate specimen, improper collection or storage technique, and failure to transport specimen in a timely fashion are causes for specimen rejection.
• Pretest antimicrobial therapy will delay or inhibit the growth of pathogens.
• Testing specimens more than 1 hr after collection may result in decreased growth or no growth of organisms.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to identify pathogenic bacterial organisms.
• Obtain a history of the patient’s complaints, including a list of known allergens.
• Obtain a history of the patient’s immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain, as appropriate, a history of sexual activity.
Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Note any recent medications that can interfere with test results.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 min. Address concerns about pain and explain that there may be some discomfort during the specimen collection. Instruct female patients not to douche for 24 hr before a cervical or vaginal specimen is to be obtained.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food or fluid restrictions, unless by medical direction.

**INRATTEST:**

Ensure that the patient has complied with medication restrictions prior to the procedure.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, specimen source (left or right as appropriate), patient age and gender, date and time of collection, and any medication the patient is taking that may interfere with the test results (e.g., antibiotics). Do not freeze the specimen or allow it to dry.

**Anal:**

Place the patient in a lithotomy or side-lying position and drape for privacy. Insert the swab 1 in. into the anal canal and rotate, moving it from side to side to allow it to come into contact with the microorganisms. Remove the swab. Place the swab in the Culturette tube, and squeeze the bottom of the tube to release the transport medium. Ensure that the end of the swab is immersed in the medium. Repeat with a clean swab if the swab is pushed into feces.

**Genital: Female Patient:**

Position the patient on the gynecological examination table with the feet up in stirrups. Drape the patient’s legs to provide privacy and reduce chilling.

Cleanse the external genitalia and perineum from front to back with towelettes provided in culture kit. Using a Culturette swab, obtain a sample of the lesion or discharge from the urethra or vulva. Place the swab in the Culturette tube, and squeeze the bottom of the tube to release the transport medium. Ensure that the end of the swab is immersed in the medium.

To obtain a vaginal and endocervical culture, insert a water-lubricated vaginal speculum. Insert the swab into the cervical orifice and rotate the swab to collect the secretions containing the microorganisms. Remove and place in the appropriate culture medium or Gen-Probe transport tube. Material from the vagina can be collected by moving a swab along the sides of the vaginal mucosa. The swab is removed and then placed in a tube of saline medium.

**Male Patient:**

To obtain a urethral culture, cleanse the penis (retracting the foreskin), have the patient milk the penis to express discharge from the urethra. Insert a swab into the urethral orifice and rotate the swab to obtain a sample of the discharge. Place the swab in the Culturette or Gen-Probe transport tube, and squeeze the bottom of the tube to release the transport medium. Ensure that the end of the swab is immersed in the medium.

**Ear:**

Cleanse the area surrounding the site with a swab containing cleaning solution to remove any contaminating material or flora that have collected in the ear canal. If needed, assist the appropriate health care provider (HCP).
in removing any cerumen that has collected.

- Insert a Culturette swab approximately ¼ in. into the external ear canal. Rotate the swab in the area containing the exudate. Carefully remove the swab, ensuring that it does not touch the side or opening of the ear canal.
- Place the swab in the Culturette tube, and squeeze the bottom of the tube to release the transport medium. Ensure that the end of the swab is immersed in the medium.

**Eye:**
- Pass a moistened swab over the appropriate site, avoiding eyelid and eyelashes unless those areas are selected for study. Collect any visible pus or other exudate. Place the swab in the Culturette or Gen-Probe transport tube, and squeeze the bottom of the tube to release the transport medium. Ensure that the end of the swab is immersed in the medium.
- An appropriate HCP should perform procedures requiring eye scrapings.

**Skin:**
- Assist the appropriate HCP in obtaining a skin sample from several areas of the affected site. If indicated, the dark, moist areas of the folds of the skin and outer growing edges of the infection where microorganisms are most likely to flourish should be selected. Place the scrapings in a collection container or spread on a slide. Aspirate any fluid from a pustule or vesicle using a sterile needle and tuberculin syringe. The exudate will be flushed into a sterile collection tube. If the lesion is not fluid filled, open the lesion with a scalpel and swap the area with a sterile cotton-tipped swab.
- Place the swab in the Culturette tube, and squeeze the bottom of the tube to release the transport medium. Ensure that the end of the swab is immersed in the medium.

**Sterile Fluid:**
- Refer to related body fluid monographs (i.e., amniotic fluid, cerebrospinal fluid, pericardial fluid, peritoneal fluid, pleural fluid, synovial fluid) for specimen collection.

**Wound:**
- Place the patient in a comfortable position, and drape the site to be cultured. Cleanse the area around the wound to remove flora indigenous to the skin.
- Place a Culturette swab in a superficial wound where the exudate is the most excessive without touching the wound edges. Place the swab in the Culturette tube, and squeeze the bottom of the tube to release the transport medium. Ensure that the end of the swab is immersed in the medium. Use more than one swab and Culturette tube to obtain specimens from other areas of the wound.
- To obtain a deep wound specimen, insert a sterile syringe and needle into the wound and aspirate the drainage. Following aspiration, inject the material into a tube containing an anaerobic culture medium.

**General:**
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- Instruct the patient to resume usual medication as directed by the HCP.
- Instruct the patient to report symptoms such as pain related to tissue inflammation or irritation.
- Instruct the patient to begin antibiotic therapy, as prescribed. Instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.
- Inform the patient that a repeat culture may be needed in 1 wk after completion of the antimicrobial regimen.
- Advise the patient that final test results may take 24 to 72 hr depending on the organism suspected, but that antibiotic therapy may be started immediately.

**Anal/Endocervical/Genital:**
- Inform the patient that final results may take from 24 hr to 4 wk, depending on the test performed.
Advise the patient to avoid sexual contact until test results are available.

Instruct the patient in vaginal suppository and medicated cream installation and administration of topical medication to treat specific conditions, as indicated.

Inform infected patients that all sexual partners must be tested for the microorganism.

Inform the patient that positive culture findings for certain organisms must be reported to a local health department official, who will question him or her regarding sexual partners.

Social and cultural considerations: Offer support, as appropriate, to patients who may be the victims of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nontackling atmosphere for discussing the risks of sexually transmitted diseases. It is also important to address problems the patient may experience (e.g., guilt, depression, anger).

Wound:

Instruct the patient in wound care and nutritional requirements (e.g., protein, vitamin C) to promote wound healing.

General:

A written report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Emphasize the importance of reporting continued signs and symptoms of the infection. Provide information regarding vaccine-preventable diseases where indicated (e.g., hepatitis A and B, human papillomavirus). Answer any questions or address any concerns voiced by the patient or family.

Instruct the patient in the use of any ordered medications (oral, topical, drops). Instruct the patient in the proper use of sterile technique for cleansing the affected site and application of dressings, as directed. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.
Culture, Bacterial, Blood

SYNONYM/ACRONYM: N/A.

SPECIMEN: Whole blood collected in bottles containing standard aerobic and anaerobic culture media; 10 to 20 mL for adult patients or 1 to 5 mL for pediatric patients.

REFERENCE VALUE: (Method: Growth of organisms in standard culture media identified by radiometric or infrared automation, or by manual reading of subculture.) Negative: no growth of pathogens.

DESCRIPTION: Blood cultures are collected whenever bacteremia or septicemia is suspected. Although mild bacteremia is found in many infectious diseases, a persistent, continuous, or recurrent bacteremia indicates a more serious condition that may require immediate treatment. Early detection of pathogens in the blood may aid in making clinical and etiologic diagnoses.

Blood culture involves the introduction of a specimen of blood into artificial aerobic and anaerobic growth culture medium. The culture is incubated for a specific length of time, at a specific temperature, and under other conditions suitable for the growth of pathogenic microorganisms. Pathogens enter the bloodstream from soft-tissue infection sites, contaminated IV lines, or invasive procedures (e.g., surgery, tooth extraction, cystoscopy). A blood culture may also be done with an antimicrobial removal device (ARD). This involves transferring some of the blood sample into a special vial containing absorbent resins that remove antibiotics from the sample before the culture is performed. The laboratory will initiate antibiotic sensitivity testing if indicated by test results. Sensitivity testing identifies the antibiotics to which the organisms are susceptible to ensure an effective treatment plan.

INDICATIONS:
• Determine sepsis in the newborn as a result of prolonged labor, early rupture of membranes, maternal infection, or neonatal aspiration
• Evaluate chills and fever in patients with infected burns, urinary tract infections, rapidly progressing tissue infection, postoperative wound sepsis, and indwelling venous or arterial catheter
• Evaluate intermittent or continuous temperature elevation of unknown origin
• Evaluate persistent, intermittent fever associated with a heart murmur
• Evaluate a sudden change in pulse and temperature with or without chills and diaphoresis
• Evaluate suspected bacteremia after invasive procedures
• Identify the cause of shock in the postoperative period

RESULT:

Positive findings in:

• Bacteremia or septicemia: *Aerobacter, Bacteroides, Brucella, Clostridium perfringens, enterococci, Escherichia coli* and other coliform bacilli, *Haemophilus influenzae, Klebsiella, Listeria monocytogenes, Pseudomonas aeruginosa, Salmonella, Staphylococcus aureus, Staphylococcus epidermidis*, and β-hemolytic streptococci.
• Plague
• Malaria (by special request, a stained capillary smear would be examined)
• Typhoid fever

Note: *Candida albicans* is a yeast that can cause disease and can be isolated by blood culture.

CRITICAL VALUES: 🚫 Note and immediately report to the health care provider (HCP) positive results and related symptoms.

INTERFERING FACTORS:

• Pretest antimicrobial therapy will delay or inhibit growth of pathogens.
• Contamination of the specimen by the skin’s resident flora may invalidate interpretation of test results.
• An inadequate amount of blood or number of blood specimens drawn for examination may invalidate interpretation of results.
• Testing specimens more than 1 hr after collection may result in decreased growth or no growth of organisms.
• Negative findings do not ensure the absence of infection.
patient, and label the appropriate specimen containers with the corresponding patient demographics, date and time of collection, and any medication the patient is taking that may interfere with test results (e.g., antibiotics). Perform a venipuncture; collect the specimen in the appropriate blood culture collection container.

The high risk for infecting a patient by venipuncture can be decreased by using an aseptic technique during specimen collection.

The contamination of blood cultures by skin and other flora can also be dramatically reduced by careful preparation of the puncture site and collection containers before specimen collection. Cleanse the rubber stoppers of the collection containers with the appropriate disinfectant as recommended by the laboratory, allow to air-dry, and cleanse with 70% alcohol. Once the vein has been located by palpation, cleanse the site with 70% alcohol followed by swabbing with an iodine solution. The iodine should be swabbed in a circular concentric motion, moving outward or away from the puncture site. The iodine should be allowed to completely dry before the sample is collected. If the patient is sensitive to iodine, a double alcohol scrub or green soap may be substituted.

If collection is performed by directly drawing the sample into a culture tube, fill the aerobic culture tube first. If collection is performed using a syringe, transfer the blood sample directly into each culture bottle.

Remove the needle, and apply direct pressure with a dry gauze to stop bleeding. Observe venipuncture site for bleeding and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

More than three sets of cultures per day do not significantly add to the likelihood of pathogen capture. Capture rates are more likely affected by obtaining a sufficient volume of blood per culture.

The use of ARDs or resin bottles is costly and controversial with respect to their effectiveness versus standard culture techniques. They may be useful in selected cases, such as when septicemia or bacteremia is suspected after antimicrobial therapy has been initiated.

</table>
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient. Instruct the patient to resume usual medication as directed by the HCP. Cleanse the iodine from the collection site. Instruct the patient to report symptoms such as pain related to tissue inflammation or irritation. Instruct the patient to report fever, chills, and other signs and symptoms of acute infection to the HCP. Instruct the patient to begin antibiotic therapy, as prescribed. Instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present. Inform the patient that preliminary results should be available in 24 to 72 hr, but final results are not available for 5 to 7 days. Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Emphasize the importance of reporting, continued signs and symptoms of the infection. Provide information regarding vaccine-preventable diseases where indicated (e.g., influenza, meningococcal, pneumococcal). Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include bone scan, bronchoscopy, complete blood count, cultures (fungal, mycobacteria, throat, sputum, viral), CSF analysis, ESR, gallium scan, gram stain, HIV-1/2 antibodies, MRI musculoskeletal, PFT, radiography bone, and TB tests.
- Refer to the Immune System table at the end of the book for related tests by body system.

**SYNONYM/ACRONYM:** Routine culture of sputum.

**SPECIMEN:** Sputum (10 to 15 mL).

**REFERENCE VALUE:** (Method: Aerobic culture on selective and enriched media; microscopic examination of sputum by Gram stain.) The presence of normal upper respiratory tract flora should be expected. Tracheal aspirates and bronchoscopy samples can be contaminated with normal flora, but transtracheal aspiration specimens should show no growth. Normal respiratory flora include *Neisseria catarrhalis, Candida albicans*, diphtheroids, a-hemolytic streptococci, and some staphylococci. The presence of normal flora does not rule out infection. A normal Gram stain of sputum contains polymorphonuclear leukocytes, alveolar macrophages, and a few squamous epithelial cells.

Access additional resources at davisplus.fadavis.com
**DESCRIPTION:** This test involves collecting a sputum specimen so the pathogen can be isolated and identified. The test results will reflect the type and number of organisms present in the specimen, as well as the antibiotics to which the identified pathogenic organisms are susceptible. Sputum collected by expectoration or suctioning with catheters and by bronchoscopy cannot be cultured for anaerobic organisms; instead, transtracheal aspiration or lung biopsy must be used. The laboratory will initiate antibiotic sensitivity testing if indicated by test results. Sensitivity testing identifies antibiotics to which the organisms are susceptible to ensure an effective treatment plan.

**INDICATIONS:**

**Culture:**
- Assist in the diagnosis of respiratory infections, as indicated by the presence or absence of organisms in culture

**Gram stain:**
- Assist in the differentiation of gram-positive from gram-negative bacteria in respiratory infection
- Assist in the differentiation of sputum from upper respiratory tract secretions, the latter being indicated by excessive squamous cells or absence of polymorphonuclear leukocytes

**RESULT:**
- The major difficulty in evaluating results is in distinguishing organisms infecting the lower respiratory tract from organisms that have colonized but not infected the lower respiratory tract. Review of the Gram stain assists in this process. The presence of greater than 25 squamous epithelial cells per low-power field (lpf) indicates oral contamination, and the specimen should be rejected. The presence of many polymorphonuclear neutrophils and few squamous epithelial cells indicates that the specimen was collected from an area of infection and is satisfactory for further analysis.

  • Bacterial pneumonia can be caused by *Streptococcus pneumoniae*, *Haemophilus influenzae*, staphylococci, and some gram-negative bacteria. Other pathogens that can be identified by culture are *Corynebacterium diphtheriae*, *Klebsiella pneumoniae*, and *Pseudomonas aeruginosa*. Some infectious agents, such as *C. diphtheriae*, are more fastidious in their growth requirements and cannot be cultured and identified without special treatment. Suspicion of infection by less commonly identified and/or fastidious organisms must be communicated to the laboratory to ensure selection of the proper procedure required for identification.

**CRITICAL VALUES:**
- *Corynebacterium diphtheriae*
- *Legionella*

Note and immediately report to the health care provider (HCP) positive results and related symptoms.

**INTERFERING FACTORS:**
- Contamination with oral flora may invalidate results.
- Specimen collection after antibiotic therapy has been initiated may result in inhibited or no growth of organisms.
Bronchoscopy:

- Make sure a written and informed consent has been signed prior to the bronchoscopy/biopsy procedure and before administering any medications.
- Other than antimicrobial drugs, there are no medication restrictions, unless by medical direction.
- The patient should fast and refrain from drinking liquids beginning at midnight the night before the procedure. Protocols may vary from facility to facility.

Expectorated Specimen:

- Additional liquids the night before may assist in liquefying secretions during expectoration the following morning.
- Assist the patient with oral cleaning before sample collection to reduce the amount of sample contamination by organisms that normally inhabit the mouth.
- Instruct the patient not to touch the edge or inside of the container with the hands or mouth.
- Other than antimicrobial drugs, there are no medication restrictions, unless by medical direction.
- There are no food or fluid restrictions, unless by medical direction.

Tracheal Suctioning:

- Assist in providing extra fluids, unless contraindicated, and proper humidification to decrease tenacious secretions.
- Inform the patient that increasing fluid intake before retiring on the night before the test aids in liquefying secretions and may make it easier to expectorate in the morning. Also explain that humidifying inspired air also helps liquefy secretions.
- Other than antimicrobial drugs, there are no medication restrictions, unless by medical direction.
- There are no food or fluid restrictions, unless by medical direction.

INTRATEST:

- Ensure that the patient has complied with dietary and medication restrictions; assure that food and fluids have been restricted for at least 8 hr prior to the bronchoscopy procedure.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to identify pathogenic bacterial organisms.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Note any recent medications that can interfere with test results.
- Review the procedure with the patient. Reassure the patient that he or she will be able to breathe during the procedure if specimen collection is accomplished via suction method. Ensure that oxygen has been administered 20 to 30 min before the procedure if the specimen is to be obtained by tracheal suctioning. Address concerns about pain related to the procedure. Atropine is usually given before bronchoscopy examinations to reduce bronchial secretions and prevent vagally induced bradycardia. Meperidine (Demerol) or morphine may be given as a sedative. Lidocaine is sprayed in the patient’s throat to reduce discomfort caused by the presence of the tube.
- Explain to the patient that the time it takes to collect a proper specimen varies according to the level of cooperation of the patient and the specimen collection site. Emphasize that sputum and saliva are not the same. Inform the patient that multiple specimens may be required at timed intervals.
- **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
Have patient remove dentures, contact lenses, eyeglasses, and jewelry. Notify the health care provider (HCP) if the patient has permanent crowns on teeth. Have the patient remove clothing and change into a gown for the procedure.

Have emergency equipment readily available. Keep resuscitation equipment on hand in case of respiratory impairment or laryngospasm after the procedure.

Avoid using morphine sulfate in patients with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Assist the patient to a comfortable position and direct the patient to breathe normally during the beginning of the general anesthesia. Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.

Observe standard precautions and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date and time of collection, and any medication the patient is taking that may interfere with test results (e.g., antibiotics). Collect the specimen in the appropriate sterile collection container.

**Bronchoscopy:**
- Record baseline vital signs.
- The patient is positioned in relation to the type of anesthesia being used. If local anesthesia is used, the patient is seated and the tongue and oropharynx are sprayed and swabbed with anesthetic before the bronchoscope is inserted. For general anesthesia, the patient is placed in a supine position with the neck hyperextended. After anesthesia, the patient is kept in supine or shifted to a side-lying position and the bronchoscope is inserted. After inspection, the samples are collected from suspicious sites by bronchial brush or biopsy forceps.

**Tracheal Suctioning:**
- Obtain the necessary equipment, including a suction device, suction kit, and Lukens tube or in-line trap.
- Position the patient with head elevated as high as tolerated.
- Put on sterile gloves. Maintain the dominant hand as sterile and the nondominant hand as clean.
- Using the sterile hand, attach the suction catheter to the rubber tubing of the Lukens tube or in-line trap. Then attach the suction tubing to the male adapter of the trap with the clean hand. Lubricate the suction-catheter with sterile saline.

**Expectorated Specimen:**
- Ask the patient to sit upright, with assistance and support (e.g., with an overbed table) as needed.
- Ask the patient to take two or three deep breaths and cough deeply. Any sputum raised should be expectorated directly into a sterile sputum collection container.
- If the patient is unable to produce the desired amount of sputum, several strategies may be attempted. One approach is to have the patient drink two glasses of water, and then assume the position for postural drainage of the upper and middle lung segments. Effective coughing may be assisted by placing either the hands or a pillow over the diaphragmatic area and applying slight pressure.
- Another approach is to place a vaporizer or other humidifying device at the bedside. After sufficient exposure to adequate humidification, postural drainage of the upper and middle lung segments may be repeated before attempting to obtain the specimen.
- Other methods may include obtaining an order for an expectorant to be administered with additional water approximately 2 hr before attempting to obtain the specimen. Chest percussion and postural drainage of all lung segments may also be employed. If the patient is still unable to raise sputum, the use of an ultrasonic nebulizer (“induced sputum”) may be necessary; this is usually done by a respiratory therapist.
Tell nonintubated patients to protrude the tongue and to take a deep breathe as the suction catheter is passed through the nostril. When the catheter enters the trachea, a reflex cough is stimulated; immediately advance the catheter into the trachea and apply suction. Maintain suction for approximately 10 sec, but never longer than 15 sec. Withdraw the catheter without applying suction. Separate the suction catheter and suction tubing from the trap, and place the rubber tubing over the male adapter to seal the unit.

For intubated patients or patients with a tracheostomy, the previous procedure is followed except that the suction catheter is passed through the existing endotracheal or tracheostomy tube rather than through the nostril. The patient should be hyperoxygenated before and after the procedure in accordance with standard protocols for suctioning these patients.

Generally, a series of three to five early morning sputum samples are collected in sterile containers.

**General:**
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods.
- Inform the patient that he or she may experience some throat soreness and hoarseness. Instruct patient to treat throat discomfort with lozenges and warm gargles when the gag reflex returns.
- Monitor vital signs and compare with baseline values every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Emergency resuscitation equipment should be readily available if the vocal cords become spastic after intubation.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Observe the patient for hemoptysis, difficulty breathing, cough, air hunger, excessive coughing, pain, or absent breathing sounds over the affected area. Report any symptoms to the HCP.
- Evaluate the patient for symptoms indicating the development of pneumothorax, such as dyspnea, tachypnea, anxiety, decreased breathing sounds, or restlessness. A chest x-ray may be ordered to check for the presence of this complication.
- Evaluate the patient for symptoms of empyema, such as fever, tachycardia, malaise, or elevated white blood cell count.
- Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.

**Nutritional considerations:** Malnutrition is commonly seen in patients with severe respiratory disease for numerous reasons including fatigue, lack of appetite, and gastrointestinal distress. Adequate intake of vitamins A and C are also important to prevent pulmonary infection and to decrease the extent of lung tissue damage.

- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient to use lozenges or
gargle for throat discomfort. Inform the patient of smoking cessation programs as appropriate. The importance of following the prescribed diet should be stressed to the patient/caregiver. Educate the patient regarding access to counseling services, as appropriate. Provide information regarding vaccine preventable diseases where indicated (e.g., diphtheria, influenza, measles, mumps, pertussis, rubella, smallpox, varicella). Answer any questions or address any concerns voiced by the patient or family.

Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include antibodies, antiglomerular basement membrane, arterial/alveolar oxygen ratio, biopsy lung, blood gases, bronchoscopy, chest x-ray, complete blood count, CT thoracic, culture (fungal, mycobacterium, throat, viral), cytology sputum, gallium scan, gram stain/acid-fast stain, HIV-1/2 antibodies, lung perfusion scan, lung ventilation scan, MRI chest, mediastinoscopy, pleural fluid analysis, PFT, and TB tests.
- Refer to the Immune and Respiratory System tables at the end of the book for related tests by body system.

**Culture, Bacterial, Stool**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Fresh random stool collected in a clean plastic container.

**REFERENCE VALUE:** (Method: Culture on selective media for identification of pathogens usually to include *Salmonella, Shigella, Escherichia coli* O157:H7, *Yersinia enterocolitica*, and *Campylobacter;* latex agglutination or enzyme immunoassay for *Clostridium* A and B toxins) Negative: No growth of pathogens. Normal fecal flora is 96% to 99% anaerobes and 1% to 4% aerobes. Normal flora present may include *Bacteroides, Candida albicans, Clostridium, Enterococcus, E. coli, Proteus, Pseudomonas,* and *Staphylococcus aureus.*

**DESCRIPTION:** Stool culture involves collecting a sample of feces so that organisms present can be isolated and identified. Certain bacteria are normally found in feces. However, when overgrowth of these organisms occurs or pathological organisms are present, diarrhea or other signs and symptoms of systemic infection occur. These symptoms are the result of damage to the intestinal tissue by the pathogenic organisms.
Routine stool culture normally screens for a small number of common pathogens, such as *Campylobacter*, *Salmonella*, and *Shigella*. Identification of other bacteria is initiated by special request or upon consultation with a microbiologist when there is knowledge of special circumstances. The laboratory will initiate antibiotic sensitivity testing if indicated by test results. Sensitivity testing identifies the antibiotics to which organisms are susceptible to ensure an effective treatment plan. Life-threatening *Clostridium difficile* infection of the bowel may occur in patients who are immunocompromised or are receiving broad-spectrum antibiotic therapy (e.g., clindamycin, ampicillin, cephalosporins). The bacteria release a toxin that causes necrosis of the colon tissue. The toxin can be more rapidly identified from a stool sample using an immunochemical method than from a routine culture. Appropriate interventions can be quickly initiated and might include IV replacement of fluid and electrolytes, cessation of broad spectrum antibiotic administration, and institution of vancomycin or metronidazole antibiotic therapy.

**INDICATIONS:**
- Assist in establishing a diagnosis for diarrhea of unknown etiology
- Identify pathogenic organisms causing gastrointestinal disease and carrier states

**RESULT:**

**Positive findings in:**
- Bacterial infection: *Aeromonas* spp., *Bacillus cereus*, *Campylobacter*, *Clostridium difficile*, *E. coli*, including serotype O157: H7, *Plesiomonas shigelloides*, *Salmonella*, *Shigella*, *Yersinia*, and *Vibrio*. Isolation of *Staphylococcus aureus* may indicate infection or a carrier state.
- Botulism: *Clostridium botulinum* (the bacteria must also be isolated from the food or the presence of toxin confirmed in the stool specimen).

**CRITICAL VALUES:** Note and immediately report to the health care provider (HCP) positive results for bacterial pathogens *Campylobacter*, *Clostridium difficile*, *E. coli* O157:H7, *Listeria*, *Rotavirus*, *Salmonella*, *Shigella*, *Vibrio*, *Yersinia*, or parasites *Acanthamoeba*, *Cyclospora*, *Cryptosporidium*, *Entamoeba histolytica*, *Giardia*, parasitic ova, proglottid and larvae.

**INTERFERING FACTORS:**
- A rectal swab does not provide an adequate amount of specimen for evaluating the carrier state and should be avoided in favor of a standard stool specimen.
- A rectal swab should never be submitted for *Clostridium* toxin studies. Specimens for *Clostridium* toxins should be refrigerated if they are not immediately transported to the laboratory as toxins degrade rapidly.
- A rectal swab should never be submitted for *Campylobacter* culture. Excessive exposure of the sample to air or room temperature may damage this bacterium so that it will not grow in the culture.
- Therapy with antibiotics before specimen collection may decrease the type and the amount of bacteria.
- Failure to transport the culture within 1 hr of collection or urine contamination of the sample may affect results.
- Barium and laxatives used less than 1 wk before the test may reduce bacterial growth.
**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to identify pathogenic bacterial organisms.
- Obtain a history of the patient’s complaints, including a list of known allergens.
- Obtain a history of the patient’s gastrointestinal and immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a history of the patient’s travel to foreign countries.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Note any recent medications that can interfere with test results.
- Review the procedure with the patient. Address concerns about pain and explain that there may be some discomfort during the specimen collection. Inform the patient that specimen collection takes approximately 5 min.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food or fluid restrictions, unless by medical direction.

**INTRATEST:**
- Ensure that the patient has complied with medication restrictions prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and any medication the patient is taking that may interfere with test results (e.g., antibiotics).
- Collect a stool specimen directly into a clean container. If the patient requires a bedpan, make sure it is clean and dry, and use a tongue blade to transfer the specimen to the container. Make sure representative portions of the stool are sent for analysis. Note specimen appearance on collection container label.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual medication as directed by the HCP.
- Instruct the patient to report symptoms such as pain related to tissue inflammation or irritation.
- Advise the patient that final test results may take up to 72 hr but that antibiotic therapy may be started immediately. Instruct the patient about the importance of completing the entire course of antibiotic therapy even if no symptoms are present. Note: Antibiotic therapy is frequently contraindicated for *Salmonella* infection unless the infection has progressed to a systemic state.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Emphasize the importance of reporting continued signs and symptoms of the infection. Provide information regarding vaccine-preventable diseases where indicated (e.g., cholera, hepatitis A and B, human papillomavirus, typhoid, yellow fever). Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include capsule endoscopy, colonoscopy, fecal analysis, ova and parasites, and proctosigmoidoscopy.
- Refer to the Gastrointestinal and Immune System tables at the end of the book for related tests by body system.

**CULTURE, BACTERIAL, THROAT OR NASOPHARYNGEAL**

**SYNONYM/ACRONYM:** Routine throat culture.

**SPECIMEN:** Throat or nasopharyngeal swab.

**REFERENCE VALUE:** (Method: Aerobic culture) No growth.

**DESCRIPTION:** The routine throat culture is a commonly ordered test to screen for the presence of group A \( \beta \)-hemolytic streptococci. *Streptococcus pyogenes* is the organism that most commonly causes acute pharyngitis. The more dangerous sequelae of scarlet fever, rheumatic heart disease, and glomerulonephritis are less frequently seen because of the early treatment of infection at the pharyngitis stage. There are a number of other bacterial agents responsible for pharyngitis. Specific cultures can be set up to detect other pathogens such as *Bordetella*, *Corynebacteria*, *Haemophilus*, or *Neisseria* if they are suspected or by special request from the health care provider (HCP). *Corynebacterium diphtheriae* is the causative agent of diphtheria. *Neisseria gonorrhoeae* is a sexually transmitted pathogen. In children, a positive throat culture for *Neisseria* usually indicates sexual abuse. The laboratory will initiate antibiotic sensitivity testing if indicated by test results. Sensitivity testing identifies the antibiotics to which the organisms are susceptible to ensure an effective treatment plan.

**INDICATIONS:**
- Assist in the diagnosis of bacterial infections such as tonsillitis, diphtheria, gonorrhea, or pertussis
- Assist in the diagnosis of upper respiratory infections resulting in bronchitis, pharyngitis, croup, and influenza
- Isolate and identify group A \( \beta \)-hemolytic streptococci as the cause of strep throat, acute glomerulonephritis, scarlet fever, or rheumatic fever

**RESULT:** Reports on cultures that are positive for group A \( \beta \)-hemolytic streptococci are generally available within 24 to 48 hr. Cultures that report on normal respiratory flora are
issued after 48 hr. Culture results of no growth for *Corynebacterium* require 72 hr to report; 48 hr are required to report negative *Neisseria* cultures.

**CRITICAL VALUES:**
- Culture: Growth of *corynebacterium* or methicillin resistant *staphylococcus aureus* (MRSA)

Note and immediately report to the health care provider (HCP) positive results and related symptoms.

**INTERFERING FACTORS:**
- Contamination with oral flora may invalidate results.
- Specimen collection after antibiotic therapy has been initiated may result in inhibited or no growth of organisms.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to identify pathogenic bacterial organisms.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Note any recent medications that can interfere with test results.
- Review the procedure with the patient. In cases of acute epiglottitis, do not swab the throat! This can cause a laryngospasm resulting in a loss of airway. A patient with epiglottitis will be sitting up and leaning forward in the tripod position with the head and jaw thrusted forward to breathe. Address concerns about pain and explain that there may be some discomfort during the specimen collection. The time it takes to collect a proper specimen varies according to the level of cooperation of the patient. Inform the patient that specimen collection takes approximately 5 min.
- There are no food or fluid restrictions, unless by medical direction.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

**INTRATEST:**
- Ensure that the patient has complied with medication restrictions prior to the procedure.
- Have emergency equipment readily available. Keep resuscitation equipment on hand in case of respiratory impairment or laryngospasm after the procedure.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and any medication the patient is taking that may interfere with test results (e.g., antibiotics).
- To collect the throat culture, tilt the patient’s head back. Swab both tonsillar pillars and oropharynx with the sterile Culturette. A tongue depressor can be used to ensure that contact with the tongue and uvula is avoided.
- A nasopharyngeal specimen is collected through the use of a flexible probe inserted through the nose and directed toward the back of the throat.
- Place the swab in the Culturette tube and squeeze the bottom of the Culturette tube to release the liquid transport medium. Ensure that the end of the swab is immersed in the liquid transport medium.
- Promptly transport the specimen to the laboratory for processing and analysis.
POST-TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual medication as directed by the HCP.

Instruct the patient to notify the HCP immediately if difficulty in breathing or swallowing occurs or if bleeding occurs.

Instruct the patient to perform mouth care after the specimen has been obtained.

Provide comfort measures and treatment such as antiseptic gargles, inhalants, and warm, moist applications as needed. A cool beverage may aid in relieving throat irritation caused by coughing or suctioning.

Administer antibiotic therapy if ordered.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Instruct the patient to use lozenges or gargle for throat discomfort. Inform the patient of smoking cessation programs as appropriate. Emphasize the importance of reporting continued signs and symptoms of the infection. Provide information regarding vaccine-preventable diseases where indicated (e.g., diphtheria, hepatitis B, HPV, influenza, measles, mumps, pertussis, pneumococcal, rubella). Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

NUTRITIONAL CONSIDERATIONS: Dehydration can be seen in patients with a bacterial throat infection due to pain with swallowing. Pain medications reduce patient’s dysphagia and allow for adequate intake of fluids and foods.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Related tests include complete blood count and group A streptococcal screen.

Refer to the Immune and Respiratory System tables at the end of the book for related tests by body system.

RELATED MONOGRAPHS: Related tests include complete blood count and group A streptococcal screen.

Refer to the Immune and Respiratory System tables at the end of the book for related tests by body system.

SYNONYM/ACRONYM: Routine urine culture.

SPECIMEN: Urine (5 mL) collected in a sterile plastic collection container.

REFERENCE VALUE: (Method: Culture on selective and enriched media) Negative: no growth.

DESCRIPTION: A urine culture involves collecting a urine specimen so that the organism causing disease can be isolated and identified. Urine can be collected by clean catch, urinary catheterization, or suprapubic aspiration. The severity of the
infection or contamination of the specimen can be determined by knowing the type and number of organisms (colonies) present in the specimen. The laboratory will initiate sensitivity testing if indicated by test results. Sensitivity testing identifies the antibiotics to which the organisms are susceptible to ensure an effective treatment plan.

Commonly detected organisms are those normally found in the genitourinary tract, including enterococci, *Escherichia coli*, *Klebsiella*, *Proteus*, and *Pseudomonas*. A culture showing multiple organisms indicates a contaminated specimen.

Colony counts of 100,000/mL or more indicate urinary tract infection (UTI).

Colony counts of 1000/mL or less suggest contamination resulting from poor collection technique.

Colony counts between 1000 and 10,000/mL may be significant depending on a variety of factors, including patient’s age, gender, number of types of organisms present, method of specimen collection, and presence of antibiotics.

**CRITICAL VALUES:**
- Extended spectrum beta lactamases (ESBL) *E coli* or *Klebsiella*
- Legionella
- Vancomycin resistant *Enterococci* (VRE)
- Note and immediately report to the health care provider (HCP) positive results and related symptoms.

**INTERFERING FACTORS:**
- Antibiotic therapy initiated before specimen collection may produce false-negative results.
- Improper collection techniques may result in specimen contamination.
- Specimen storage for longer than 30 min at room temperature or 24 hr at refrigerated temperature may result in overgrowth of bacteria and false-positive results.
- Results of urine culture are often interpreted along with routine urinalysis findings.
- Discrepancies between culture and urinalysis may be reason to re-collect the specimen.

**INDICATIONS:**
- Assist in the diagnosis of suspected UTI
- Determine the sensitivity of significant organisms to antibiotics
- Monitor the response to UTI treatment

**RESULT:**

*Positive findings in:*
- UTIs

*Negative findings in: N/A*

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to identify pathogenic bacterial organisms.
- Obtain a history of the patient’s complaints, including a list of known allergens.
- Obtain a history of the patient’s genitourinary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
Note any recent medications that can interfere with test results. Review the procedure with the patient. Address concerns about pain and explain that there may be some discomfort during the specimen collection. Inform the patient that specimen collection depends on patient cooperation and usually takes approximately 5 to 10 min.

*Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food or fluid restrictions, unless by medical direction.

Instruct the patient on clean-catch procedure and provide necessary supplies.

**INTRATEST:**

Ensure that the patient has complied with medication restrictions prior to the procedure.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, method of specimen collection, and any medications the patient has taken that may interfere with test results (e.g., antibiotics).

**Clean-Catch Specimen:**

Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.

Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

**Pediatric Urine Collector:**

Put on gloves. Appropriately cleanse the genital area, and allow the area to dry. Remove the covering over the adhesive strips on the collector bag and apply over the genital area. Diaper the child. When specimen is obtained, place the entire collection bag in a sterile urine container.

**Indwelling Catheter:**

Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

**Urinary Catheterization:**

Place female patient in lithotomy position or male patient in supine position. Using sterile technique, open the straight urinary catheterization kit and perform urinary catheterization. Place the retained urine in a sterile specimen container.

**Suprapubic Aspiration:**

Place the patient in supine position. Cleanse the area with antiseptic, and drape with sterile drapes. A needle is inserted through the skin into the bladder. A syringe attached to the needle is used to aspirate the urine sample. The needle is then removed and a sterile dressing is applied to the site. Place the sterile sample in a sterile specimen container.

Do not collect urine from the pouch from a patient with a urinary diversion (e.g., ileal conduit). Instead, perform catheterization through the stoma.

**General:**

Promptly transport the specimen to the laboratory for processing and analysis. If a delay in transport is expected, add an equal volume of 50% alcohol to the specimen as a preservative.

**POST-TEST:**

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Instruct the patient to resume usual medication as directed by the HCP.

Instruct the patient to report symptoms such as pain related to tissue inflammation, pain or irritation during void,
bladder spasms, or alterations in urinary elimination.

- Observe for signs of inflammation if the specimen is obtained by suprapubic aspiration.
- Administer antibiotic therapy as ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.

**Nutritional considerations:** Instruct the patient to increase water consumption by drinking 8 to 12 glasses of water to assist in flushing the urinary tract. Instruct the patient to avoid alcohol, caffeine, and carbonated beverages, which can cause bladder irritation.

- Prevention of UTIs includes increasing daily water consumption, urinating when urge occurs, wiping the perineal area from front to back after urination/defecation, and urinating immediately after intercourse. Prevention also includes maintaining the normal flora of the body. Patients should avoid using spermicidal creams with diaphragms or condoms (when recommended by a HCP), becoming constipated, douching, taking bubble baths, wearing tight-fitting garments, and using deodorizing feminine hygiene products that alter the body’s normal flora and increase susceptibility to UTIs.

- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Emphasize the importance of reporting continued signs and symptoms of the infection. Instruct patient on the proper technique for wiping the perineal area (front to back) after a bowel movement. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include complete blood count, complete blood count, WBC count and differential, cystometry, cystoscopy, cystourethrography voiding, cytology urine, gram stain, renogram, and UA.
- Refer to the Genitourinary and Immune System tables at the end of the book for related tests by body system.

---

**Culture, Fungal**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Hair, skin, nail, pus, sterile fluids, blood, bone marrow, stool, bronchial washings, sputum, or tissue samples collected in a sterile plastic, tightly capped container.

**REFERENCE VALUE:** (Method: Culture on selective media; macroscopic and microscopic examination) No presence of fungi.
DESCRIPTION: Fungi, organisms that normally live in soil, can be introduced into humans through the accidental inhalation of spores or inoculation of spores into tissue through trauma. Individuals most susceptible to fungal infection usually are debilitated by chronic disease, are receiving prolonged antibiotic therapy, or have impaired immune systems. Fungal diseases may be classified according to the involved tissue type: dermatophytoses involve superficial and cutaneous tissue; there are also subcutaneous and systemic mycoses.

INDICATIONS:
- Determine antimicrobial sensitivity of the organism
- Isolate and identify organisms responsible for nail infections or abnormalities
- Isolate and identify organisms responsible for skin eruptions, drainage, or other evidence of infection

RESULT:
Positive findings in:
- Blood
  - Candida albicans
  - Histoplasma capsulatum
- Cerebrospinal fluid
  - Coccidioides immitis
  - Cryptococcus neoformans
  - Members of the order Mucorales
  - Paracoccidioides brasiliensis
  - Sporothrix schenckii
- Hair
  - Epidermophyton
  - Microsporum
  - Trichophyton
- Nails
  - Candida albicans
  - Cephalosporium
  - E. albicans
  - C. neoformans
  - A. brasiliensis
  - M. brasiliensis

CRITICAL VALUES: N/A.

INTERFERING FACTORS:
Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to identify pathogenic fungal organisms.
- Obtain a history of the patient’s complaints, including a list of known allergens.
- Obtain a history of the patient’s immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Note any recent medications that can interfere with test results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 min.
Address concerns about pain and explain that there may be some discomfort during the specimen collection.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food or fluid restrictions, unless by medical direction.

---

**INTRATEST:**

- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Instructions regarding the appropriate transport materials for blood, bone marrow, bronchial washings, sputum, sterile fluids, stool, and tissue samples should be obtained from the laboratory. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date, and time of collection.
- Promptly transport the specimen to the laboratory for processing and analysis.

**Skin:**

- Clean the collection site with 70% alcohol. Scrape the peripheral margin of the collection site with a sterile scalpel or wooden spatula. Place the scrapings in a sterile collection container.

**Hair:**

- Fungi usually grow at the base of the hair shaft. Infected hairs can be identified by using a Wood's lamp in a darkened room. A Wood's lamp provides rays of ultraviolet light at a wavelength of 366 nm, or 3660 Å. Infected hairs fluoresce a bright yellow-green when exposed to light from the Wood's lamp. Using tweezers, pluck hair from skin.

**Nails:**

- Ideally, softened material from the nail bed is sampled from beneath the nail plate. Alternatively, shavings from the deeper portions of the nail itself can be collected.

---

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct patient to begin antifungal therapy, as prescribed. Instruct the patient in the importance of completing the entire course of antifungal therapy even if no symptoms are present.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Emphasize the importance of reporting continued signs and symptoms of the infection. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

---

**RELATED MONOGRAPHS:**

- Related tests include relevant biopsies (lung, lymph node, skin), bronchoscopy, cultures (blood, mycobacteria, throat, sputum, viral), CSF analysis, gallium scan, HIV-1/2 antibodies, pulmonary function tests, and TB tests.
- Refer to the Immune System table at the back of the book for related tests by body system.
**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Urine, semen, blood, body fluid, stool, tissue, or swabs from the affected site.

**REFERENCE VALUE:** (Method: Culture in special media, enzyme-linked immunoassays, direct fluorescent antibody techniques, latex agglutination, immunoperoxidase techniques) No virus isolated.

**DESCRIPTION:** Viruses, the most common cause of human infection, are submicroscopic organisms that invade living cells. They can be classified as either RNA- or DNA-type viruses. Viral titers are highest in the early stages of disease before the host has begun to manufacture significant antibodies against the invader. Specimens need to be collected as early in the disease process as possible.

**INDICATIONS:**
Assist in the identification of viral infection

**RESULT:**

**Positive findings in:**
- Acquired immunodeficiency syndrome
  - Human immunodeficiency virus (HIV)
- Acute respiratory failure
  - Hantavirus
- Anorectal infections
  - Herpes simplex virus (HSV)
  - Human papillomavirus (HPV)
- Bronchitis
  - Parainfluenza virus
  - Respiratory syncytial virus (RSV)
- Cervical cancer
  - Human papillomavirus
- Condylomata
  - Human papillomavirus
- Conjunctivitis/keratitis
  - Adenovirus
  - Epstein-Barr virus
  - HSV
  - Measles virus
  - Parvovirus
  - Rubella virus
  - Varicella-zoster virus
- Croup
  - Parainfluenza virus
  - RSV
- Cutaneous infection with rash
  - Enteroviruses
  - HSV
  - Varicella-zoster virus
- Encephalitis
  - Enteroviruses
  - Flaviviruses
  - HSV
  - HIV
  - Measles virus
  - Rabies virus
  - Togaviruses
- Febrile illness with rash
  - Coxsackieviruses
  - Echovirus
- Gastroenteritis
  - Norwalk virus
  - Rotavirus
- Genital herpes
  - HSV-1
  - HSV-2
• Genital warts
  HPV
• Hemorrhagic cystitis
  Adenovirus
• Hemorrhagic fever
  Ebola virus
  Hantavirus
  Lassa virus
  Marburg virus
• Herpangina

• Upper respiratory tract infection
  Adenovirus
  Coronavirus
  Influenza virus
  Parainfluenza virus
  RSV
  Rhinovirus

**CRITICAL VALUES:**
Positive RSV, influenza, and varicella zoster cultures should be reported immediately to the requesting health care provider (HCP).

**INTERFERING FACTORS:**
Viral specimens are unstable. Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to identify pathogenic viral organisms.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s gastrointestinal, genitourinary, immune, reproductive, and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Note any recent medications that can interfere with test results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 min. Address concerns about pain and explain that there may be some discomfort during the specimen collection.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
INTRATEST:

- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, exact site, contact person for notification of results, and other pertinent information (e.g., patient immunocompromised owing to organ transplant, radiation, or chemotherapy).
- Instructions regarding the appropriate transport materials for blood, bronchial washings, sputum, sterile fluids, stool, and tissue samples should be obtained from the laboratory. The type of applicator used to obtain swabs should be verified by consultation with the testing laboratory personnel.
- The appropriate viral transport material should be obtained from the laboratory. Nasopharyngeal washings or swabs for RSV testing should be immediately placed in cold viral transport media.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Nutritional considerations: Dehydration can be seen in patients with viral infections due to loss of fluids through fever, diarrhea, and/or vomiting. Antipyretic medication includes acetaminophen to decrease fever and allow for adequate intake of fluids and foods. Do not give acetylsalicylic acid to patients with a viral illness as there is an increased risk of Reye’s syndrome.
- Sensitivity to social and cultural issues: Offer support, as appropriate, to patients who may be the victims of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nontreating atmosphere for discussing the risks of sexually transmitted diseases. It is also important to address problems the patient may experience (e.g., guilt, depression, anger).
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Provide information regarding vaccine-preventable diseases where indicated (e.g., encephalitis, hepatitis A and B, HPV, influenza, measles, mumps, polio, rubella, smallpox, varicella, yellow fever). Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include relevant alveolar/arterial gradient, β-2–microglobulin, barium enema, biopsy (cervical, intestinal, kidney, liver, lung, lymph node, muscle, skin), blood gases, bronchoscopy, CD4/CD8 ratio, CSF analysis, chlamydia group antibody, chest x-ray, cultures (anal, blood, ear, eye, fungal, genital, mycobacteria, skin, sputum, stool, throat, urine, wound), cytology (sputum, urine), gallium scan, gastric emptying scan, lung perfusion scan, lung ventilation scan, PAP smear, pericardial fluid analysis, plethysmography, pulse oximetry, PFT, slit-lamp biomicroscopy, syphilis serology, TB tests, and viral serology tests (hepatitis, HIV, HTLV, infectious mono, mumps, rubella, rubeola, varicella).
- Refer to the Gastrointestinal, Genitourinary, Immune, Reproductive, and Respiratory System tables at the end of the book for related tests by body system.
Cystometry

SYNONYM/ACRONYM: Urodynamic testing of bladder function, CMG.

AREA OF APPLICATION: Bladder, urethra.

CONTRAST: None.

DESCRIPTION: Cystometry evaluates the motor and sensory function of the bladder when incontinence is present or neurological bladder dysfunction is suspected, and monitors the effects of treatment for the abnormalities. This noninvasive manometric study measures the bladder pressure and volume characteristics in milliliters of water (cm H$_2$O) during the filling and emptying phases. The test provides information about bladder structure and function that can lead to uninhibited bladder contractions, sensations of bladder fullness and need to void, and ability to inhibit voiding. These abnormalities cause incontinence and other impaired patterns of micturition. Cystometry can be performed with cystoscopy and sphincter electromyography.

INDICATIONS:
- Detect congenital urinary abnormalities
- Determine cause of bladder dysfunction and pathology
- Determine cause of recurrent urinary tract infections (UTIs)
- Determine cause of urinary retention
- Determine type of incontinence: functional (involuntary and unpredictable), reflex (involuntary when a specific volume is reached), stress (weak pelvic muscles), total (continuous and unpredictable), urge (involuntary when urgency is sensed), and psychological (e.g., dementia, confusion affecting awareness)
- Determine type of neurogenic bladder (motor or sensory)
- Evaluate the management of neurological bladder before surgical intervention
- Evaluate postprostatectomy incontinence
- Evaluate signs and symptoms of urinary elimination pattern dysfunction
- Evaluate urinary obstruction in male patients experiencing urinary retention
- Evaluate the usefulness of drug therapy on detrusor muscle function and tonicity and on internal and external sphincter function
- Evaluate voiding disorders associated with spinal cord injury

RESULT:

Normal findings in:
- Absence of residual urine (0 mL)
- Normal sensory perception of bladder fullness, desire to void, and ability to inhibit urination; appropriate response to temperature (hot and cold)
- Normal bladder capacity: 350 to 750 mL for men and 250 to 550 mL for women
• Normal functioning bladder pressure: 8 to 15 cm H₂O
• Normal sensation of fullness: 40 to 100 cm H₂O or 300 to 500 mL
• Normal bladder pressure during voiding: 30 to 40 cm H₂O
• Normal detrusor pressure: less than 10 cm H₂O
• Normal urge to void: 150 to 450 mL
• Normal filling pattern
• Urethral pressure that is higher than bladder pressure, ensuring continence

**Abnormal findings in:**
• Flaccid bladder that fills without contracting
• Inability to perceive bladder fullness
• Inability to initiate or maintain urination without applying external pressure
• Sensory or motor paralysis of bladder
• Total loss of conscious sensation and vesical control or uncontrolable micturition (incontinence)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

**This procedure is contraindicated for:**
• Patients with acute UTIs because the study can cause infection to spread to the kidneys
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
• Patients with urethral obstruction
• Patients with cervical cord lesions because they may exhibit autonomic dysreflexia, as seen by bradycardia, flushing, hypertension, diaphoresis, and headache
• Inability to catheterize the patient

**Factors that may impair the results of the examination:**
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Inability of the patient to void in a supine position or straining to void during the study
• A high level of patient anxiety or embarrassment, which may interfere with the study, making it difficult to distinguish whether the results are due to stress or organic pathology
• Administration of drugs that affect bladder function, such as muscle relaxants or antihistamines

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses bladder function.
- Obtain a history of the patient’s complaints including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, and dyes.
- Obtain a history of the patient’s genitourinary and renal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Assess hematological status, blood-clotting ability, and urinalysis findings for abnormalities.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced.
during the test. Inform the patient that the procedure is performed in a special urology room or in a clinic setting by the health care provider (HCP), with support staff, and takes approximately 30 to 45 min.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient to report pain, sweating, nausea, headache, and the urge to void during the study.

Instruct the patient to remove jewelry and other metallic objects in the area to be examined.

There are no food, fluid, or medication restrictions, unless by medical direction.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to change into the gown, robe, and foot coverings provided, but not to void.
- Position the patient in a supine or lithotomy position on the examining table. If spinal cord injury is present, the patient can remain on a stretcher in a supine position and be draped appropriately.
- Ask the patient to void. During voiding, note characteristics such as start time; force and continuity of the stream; volume voided; presence of dribbling, straining, or hesitancy; and stop time.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still during the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- A urinary catheter is inserted into the bladder under sterile conditions, and residual urine is measured and recorded. A test for sensory response to temperature is done by instilling 30 mL of room-temperature sterile water followed by 30 mL of warm sterile water. Sensations are assessed and recorded.
- Fluid is removed from the bladder, and the catheter is connected to a cystometer that measures the pressure. Sterile normal saline, distilled water, or carbon dioxide gas is instilled in controlled amounts into the bladder. When the client indicates the urge to void, the bladder is considered full. The patient is instructed to void, and urination amounts as well as start and stop times are then recorded.
- Pressure and volume readings are recorded and graphed for response to heat, full bladder, urge to void, and ability to inhibit voiding. The patient is requested to void without straining, and pressures are taken and recorded during this activity.
- After completion of voiding, the bladder is emptied of any other fluid, and the catheter is withdrawn, unless further testing is planned.
- Further testing may be done to determine if abnormal bladder function is being caused by muscle incompetence or interruption in innervation; anticholinergic medication (e.g., atropine) or cholinergic medication (e.g., bethanechol [Urecholine]) can be injected and the study repeated in 20 or 30 min.

**POST-TEST:**

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Monitor fluid intake and urinary output for 24 hr after the procedure.
- Monitor vital signs after the procedure every 15 min for 2 hr or as directed. Elevated temperature may indicate infection. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Inform the patient that he or she may experience burning or discomfort on urination for a few voidings after the procedure.
- Emphasize that persistent flank or suprapubic pain, fever, chills, blood in the urine, difficulty urinating, or change in urinary pattern must be reported immediately to the HCP.
- Recognize anxiety related to test results. Discuss the implications of
abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include bladder cancer markers, calculus kidney stone panel, chlamydia group antibody, CT pelvis, culture urine, cytology urine, IVP, MRI pelvis, UA, and US pelvis.
- Refer to the Genitourinary and Renal System tables in the back of the book for related tests by body system.

---

**Cystoscopy**

**SYNONYM/ACRONYM:** Cystoureterography, cystourethrography, prostatography.

**AREA OF APPLICATION:** Bladder, urethra, ureteral orifices.

**CONTRAST:** None.

**DESCRIPTION:** Cystoscopy provides direct visualization of the urethra, urinary bladder, and ureteral orifices—areas not usually visible with x-ray procedures. This procedure is also used to obtain specimens and treat pathology associated with the aforementioned structures. Cystoscopy is accomplished by transurethral insertion of a cystoscope into the bladder. Rigid cystoscopes contain an obturator and a telescope with a lens and light system; there are also flexible cystoscopes, which use fiberoptic technology. The procedure may be performed during or after ultrasonography or radiography, or during urethroscopy or retrograde pyelography.

**INDICATIONS:**
- Coagulate bleeding areas
- Determine the possible source of persistent urinary tract infections
- Determine the source of hematuria of unknown cause
- Differentiate, through tissue biopsy, between benign and cancerous lesions involving the bladder
- Dilate the urethra and ureters
- Evacuate blood clots and perform fulguration of bleeding sites within the lower urinary tract
- Evaluate changes in urinary elimination patterns
- Evaluate the extent of prostatic hyperplasia and degree of obstruction
- Evaluate the function of each kidney by obtaining urine samples via ureteral catheters

Access additional resources at davisplus.fadavis.com
• Evaluate urinary tract abnormalities such as dysuria, frequency, retention, inadequate stream, urgency, and incontinence
• Identify and remove polyps and small tumors (including by fulguration) from the bladder
• Identify congenital anomalies, such as duplicate ureters, ureteroceles, urethral or ureteral strictures, diverticula, and areas of inflammation or ulceration
• Implant radioactive seeds
• Place ureteral catheters to drain urine from the renal pelvis or for retrograde pyelography
• Place ureteral stents and resect prostate gland tissue (transurethral resection of the prostate)
• Remove renal calculi from the bladder or ureters
• Resect small tumors

RESULT:

Normal findings in:
• Normal ureter, bladder, and urethral structure

Abnormal findings in:
• Diverticulum of the bladder, fistula, stones, and strictures
• Inflammation or infection
• Obstruction
• Polyps
• Prostatic hypertrophy or hyperplasia
• Renal calculi
• Tumors
• Ureteral or urethral stricture
• Urinary tract malformation and congenital anomalies

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
• Patients with bleeding disorders because instrumentation may lead to excessive bleeding from the lower urinary tract
• Patients with acute cystitis or urethritis because instrumentation could allow bacteria to enter the bloodstream, resulting in septicemia

Factors that may impair the results of the examination:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assess the urinary tract.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, and dyes.
• Obtain a history of results of the patient’s genitourinary system, symptoms, and previously performed laboratory tests and diagnostic and surgical procedures.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
• Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
Note the last time and dose of medication taken. Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a special cystoscopy suite near or in the surgery department by a health care provider (HCP), with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. Restrict food and fluids for 8 hr if the patient is having general or spinal anesthesia. For local anesthesia, allow only clear liquids 8 hr before the procedure. Protocols may vary from facility to facility. Obtain and record the patient’s vital signs. Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 8 hr depending on the anesthetic chosen for the procedure.
- Administer ordered preoperative sedation.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.
- Position patient on the examination table draped and with legs in stirrups. If general or spinal anesthesia is to be used, it is administered before positioning the patient on the table.
- Cleanse external genitalia with antiseptic solution. If local anesthetic is used, it is instilled into the urethra and retained for 5 to 10 min. A penile clamp may be used for male patients to aid in retention of anesthetic.
- The HCP inserts a cystoscope or a urethroscope to examine the urethra before cystoscopy. The urethroscope has a sheath that may be left in place, and the cystoscope is inserted through it, avoiding multiple instrumentations. After insertion of the cystoscope, a sample of residual urine may be obtained for culture or other analysis. The bladder is irrigated via an irrigation system attached to the scope. The irrigation fluid aids in bladder visualization.
- If a prostatic tumor is found, a biopsy specimen may be obtained by means of a cytology brush or biopsy forceps inserted through the scope. If the tumor is small and localized, it can be excised and fulgurated. This procedure is termed transurethral resection of the bladder. Polyps can also be identified and excised.
- Ulcers or bleeding sites can be fulgurated using electrocautery.
- Renal calculi can be crushed and removed from the ureters and bladder.
- Ureteral catheters can be inserted via the scope to obtain urine samples from each kidney for comparative analysis and radiographic studies.
- Ureteral and urethral strictures can also be dilated during this procedure.
- Upon completion of the examination and related procedures, the cystoscope is withdrawn.
- Place obtained specimens in proper containers, label them properly, and immediately transport them to the laboratory.

POST-TEST:

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume his or her usual diet and medications, as directed by the HCP.
- Encourage the patient to drink increased amounts of fluids (125 mL/hr for 24 hr) after the procedure.
- Monitor vital signs and neurologic status every 15 min for 1 hr, then every
2 hr for 4 hr, and then as ordered by the HCP. Take the temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

- Monitor fluid intake and urinary output for 24 hr after the procedure. Decreased urine output may indicate bladder edema or perforation caused by forceful advancement of instrumentation.
- Inform the patient that burning or discomfort on urination can be experienced for a few voidings after the procedure and that the urine may be blood-tinged for the first and second voidings after the procedure.
- Emphasize that persistent flank or suprapubic pain, fever, chills, blood in the urine, difficulty urinating, or change in urinary pattern must be reported immediately to the HCP.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include biopsy kidney, biopsy prostate, calculus kidney stone panel, chlamydia group antibody, CT pelvis, culture urine, cytology urine, IVP, MRI pelvis, PSA, US pelvis, and UA.
- Refer to the Genitourinary System table in the back of the book for related tests by body system.

### Cystourethrography, Voiding

**SYNONYM/ACRONYM:** Voiding cystography (VCU).

**AREA OF APPLICATION:** Bladder, urethra.

**CONTRAST:** Radiopaque iodine-based contrast medium.

**DESCRIPTION:** Voiding cystourethrography involves visualization of the bladder filled with contrast medium instilled through a catheter by use of a syringe or gravity, and, after the catheter is removed, the excretion of the contrast medium. Excretion or micturition is recorded electronically or on videotape for confirmation or exclusion of ureteral reflux and evaluation of the urethra. Fluoroscopic or plain images may also be taken to record bladder filling and emptying. This procedure is often used to evaluate chronic urinary tract infections (UTIs).
**INDICATIONS:**
- Assess the degree of compromise of a stenotic prostatic urethra
- Assess hypertrophy of the prostate lobes
- Assess ureteral stricture
- Confirm the diagnosis of congenital lower urinary tract anomaly
- Evaluate abnormal bladder emptying and incontinence
- Evaluate the effects of bladder trauma
- Evaluate possible cause of frequent UTIs
- Evaluate the presence and extent of ureteral reflux
- Evaluate the urethra for obstruction and strictures

**RESULT:**

*Normal findings in:*
- Normal bladder and urethra structure and function

*Abnormal findings in:*
- Bladder trauma
- Bladder tumors
- Hematomas
- Neurogenic bladder
- Pelvic tumors
- Prostatic enlargement
- Ureteral stricture
- Ureterocele
- Urethral diverticula
- Vesicoureteral reflux

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

*This procedure is contraindicated for:*
- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients who are bleeding disorders.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Patients with UTI, obstruction, or injury.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.

*Factors that may impair clear imaging:*
- Metallic objects within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure

*Other considerations:*
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the examination room with the patient should wear a protective lead apron, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the urinary tract.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, and dyes.
- Obtain a history of results of the patient’s genitourinary system, symptoms, and previously performed laboratory tests and diagnostic and surgical procedures. Ensure that the results of blood tests are obtained and recorded before the procedure, especially coagulation tests, BUN and creatinine, if contrast medium is to be used.
- Ensure that this procedure is performed before an upper gastrointestinal study or barium swallow.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in the radiology department by a HCP, with support staff, and takes approximately 30 to 60 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Inform the patient that he or she may receive a laxative the night before the test or an enema or a cathartic the morning of the test, as ordered.
- Instruct the patient to increase fluid intake the day before the test, and to have only clear fluids 8 hr before the test.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:
- Ensure that the patient has complied with dietary restrictions. Assess for completion of bowel preparation if ordered.
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Observe standard precautions, and follow the general guidelines in Appendix A. Instruct the patient to cooperate fully and to follow directions.
- Insert a Foley catheter before the procedure, if ordered. Inform the patient that he or she may feel some pressure when the catheter is inserted and when the contrast medium is instilled through the catheter.
- Place the patient on the table in a supine or lithotomy position.
- A kidney, ureter, and bladder film or plain radiograph is taken to ensure that no barium or stool obscures visualization of the urinary system.
- A catheter is filled with contrast medium to eliminate air pockets and is inserted until the balloon reaches the meatus if not previously inserted in the patient.
Cytology, Sputum

SYNONYM/ACRONYM: N/A.

SPECIMEN: Sputum (10 to 15 mL) collected on three to five consecutive first-morning, deep-cough expectorations.

REFERENCE VALUE: (Method: Macroscopic and microscopic examination) Negative for abnormal cells, fungi, ova, and parasites.

POST-TEST:

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet and medications, as directed by the HCP.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

Monitor for reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Maintain the patient on adequate hydration after the procedure. Encourage the patient to drink increased amounts of fluids (125 mL/hr for 24 hr) after the procedure to prevent stasis and bacterial buildup.

Monitor fluid intake and urinary output for 24 hr after the procedure. Decreased urinary output may indicate impending renal failure or edema caused by instrumentation.

Monitor for signs of sepsis: fever, chills, and severe pelvic pain.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include biopsy prostate, bladder cancer markers, BUN, CT pelvis, creatinine cytology urine, IVP, MRI pelvis, PSA, PT/INR and US pelvis.

Refer to the Genitourinary System table at the back of the book for related tests by body system.
DESCRIPTION: Cytology is the study of the origin, structure, function, and pathology of cells. In clinical practice, cytological examinations are generally performed to detect cell changes resulting from neoplastic or inflammatory conditions. Sputum specimens for cytological examinations may be collected by expectoration alone, by suctioning, by lung biopsy, during bronchoscopy, or by expectoration after bronchoscopy. A description of the method of specimen collection by bronchoscopy and biopsy is found in the monograph titled “Biopsy, Lung.”

INDICATIONS:
- Assist in the diagnosis of lung cancer
- Assist in the identification of *Pneumocystis carinii* in persons with AIDS
- Detect known or suspected fungal or parasitic infection involving the lung
- Detect known or suspected viral disease involving the lung
- Screen cigarette smokers for neoplastic (nonmalignant) cellular changes
- Screen patients with history of acute or chronic inflammatory or infectious lung disorders, which may lead to benign atypical or metaplastic changes

RESULT: (Method: Microscopic examination)
The method of reporting results of cytology examinations varies according to the laboratory performing the test. Terms used to report results may include *negative* (no abnormal cells seen), *inflammatory*, *benign atypical*, *suspect for neoplasm*, and *positive for neoplasm*.

Positive findings in:
- Infections caused by fungi, ova, or parasites
- Lipoid or aspiration pneumonia, as seen by lipid droplets contained in macrophages
- Neoplasms
- Viral infections and lung disease

CRITICAL VALUES:
If the patient becomes hypoxic or cyanotic, remove catheter immediately and administer oxygen.

If patient has asthma or chronic bronchitis, watch for aggravated bronchospasms with use of normal saline or acetylcysteine in an aerosol. It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

INTERFERING FACTORS:
- Improper specimen fixation may be cause for specimen rejection.
- Improper technique used to obtain bronchial washing may be cause for specimen rejection.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test helps identify cellular changes associated with neoplasms or organisms that result in respiratory tract infections. When the actual infectious organisms are identified by cytology, inform the patient that the findings will be confirmed by culture.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
Obtain a history of the patient’s immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Note any recent procedures that can interfere with test results.

Review the procedure with the patient. If the laboratory has provided a container with fixative, instruct the patient that the fixative contents of the specimen collection container should not be ingested or otherwise removed. Instruct the patient not to touch the edge or inside of the specimen container with the hands or mouth. Inform the patient that three samples may be required, on three separate mornings, either by passing a small tube (tracheal catheter) and adding suction or by expectoration. The time it takes to collect a proper specimen varies according to the level of cooperation of the patient and the specimen collection procedure. Address concerns about pain related to the procedure. Atropine is usually given before bronchoscopy examinations to reduce bronchial secretions and to prevent vagally induced bradycardia. Meperidine (Demerol) or morphine may be given as a sedative. Lidocaine is sprayed in the patient’s throat to reduce discomfort caused by the presence of the tube.

Reassure the patient that he or she will be able to breathe during the procedure if specimen collected is accomplished via suction method. Ensure that oxygen has been administered 20 to 30 min before the procedure if the specimen is to be obtained by tracheal suctioning.

Assist in providing extra fluids, unless contraindicated, and proper humidification to loosen tenacious secretions. Inform the patient that increasing fluid intake before retiring on the night before the test aids in liquefying secretions and may make it easier to expectorate in the morning. Also explain that humidifying inspired air also helps to liquefy secretions.

Assist with mouth care (brushing teeth or rinsing mouth with water), if needed, before collection so as not to contaminate the specimen by oral secretions.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during and after the procedure.

For specimens collected by suctioning or expectoration without bronchoscopy, there are no food, fluid, or medication restrictions, unless by medical direction.

Instruct the patient to fast and refrain from taking liquids from midnight the night before if bronchoscopy or biopsy is to be performed. Protocols may vary from facility to facility.

Make sure a written and informed consent has been signed prior to the bronchoscopy or biopsy procedure and before administering any medications.

[intratest]

Ensure that the patient has complied with dietary restrictions; assure that food and liquids have been restricted for at least 6 to 8 hr prior to the procedure.

Have patient remove dentures, contact lenses, eyeglasses, and jewelry. Notify the HCP if the patient has permanent crowns on teeth. Have the patient remove clothing and change into a gown for the procedure.

Have emergency equipment readily available. Keep resuscitation equipment on hand in the case of respiratory impairment or laryngospasm after the procedure.

Avoid using morphine sulfate in those with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
Assist the patient to a comfortable position, and direct the patient to breathe normally during the beginning of the general anesthesia. Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date and time of collection, and any medication the patient is taking that may interfere with test results (e.g., antibiotics). Cytology specimens may also be expressed onto a glass slide and sprayed with a fixative or 95% alcohol.

**Bronchoscopy:**
- Record baseline vital signs.
- The patient is positioned in relation to the type of anesthesia being used. If local anesthesia is used, the patient is seated, and the tongue and oropharynx are sprayed and swabbed with anesthetic before the bronchoscope is inserted. For general anesthesia, the patient is placed in a supine position with the neck hyperextended. After anesthesia, the patient is kept in supine or shifted to side-lying position, and the bronchoscope is inserted. After inspection, the samples are collected from suspicious sites by bronchial brush or biopsy forceps.

**EXPECTORATED SPECIMEN:**
- Ask the patient to sit upright, with assistance and support (e.g., with an overbed table) as needed.
- Ask the patient to take two or three deep breaths and cough deeply. Any sputum raised should be expectorated directly into a sterile sputum collection container.
- If the patient is unable to produce the desired amount of sputum, several strategies may be attempted. One approach is to have the patient drink two glasses of water, and then assume the position for postural drainage of the upper and middle lung segments. Effective coughing may be assisted by placing either the hands or a pillow over the diaphragmatic area and applying slight pressure.
- Another approach is to place a vaporizer or other humidifying device at the bedside. After sufficient exposure to adequate humidification, postural drainage of the upper and middle lung segments may be repeated before attempting to obtain the specimen.
- Other methods may include obtaining an order for an expectorant to be administered with additional water approximately 2 hr before attempting to obtain the specimen. Chest percussion and postural drainage of all lung segments may also be employed. If the patient is still unable to raise sputum, the use of an ultrasonic nebulizer ("induced sputum") may be necessary; this is usually done by a respiratory therapist.

**Tracheal Suctioning:**
- Obtain the necessary equipment, including a suction device, suction kit, and Lukens tube or in-line trap.
- Position the patient with head elevated as high as tolerated.
- Put on sterile gloves. Maintain the dominant hand as sterile and the nondominant hand as clean.
- Using the sterile hand, attach the suction catheter to the rubber tubing of the Lukens tube or in-line trap. Then attach the suction tubing to the male adapter of the trap with the clean hand. Lubricate the suction catheter with sterile saline.
- Tell nonintubated patients to protrude the tongue and to take a deep breathe as the suction catheter is passed through the nostril. When the catheter enters the trachea, a reflex cough is stimulated; immediately advance the catheter into the trachea and apply suction. Maintain suction for approximately 10 sec, but never longer than 15 sec. Withdraw the catheter without applying suction. Separate the suction catheter and suction tubing.
from the trap, and place the rubber tubing over the male adapter to seal the unit.

For intubated patients or patients with a tracheostomy, the previous procedure is followed except that the suction catheter is passed through the existing endotracheal or tracheostomy tube rather than through the nostril. The patient should be hyperoxygenated before and after the procedure in accordance with standard protocols for suctioning these patients.

Generally, a series of three to five early-morning sputum samples are collected in sterile containers.

**General:**
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet, as directed by the HCP. Assess the patient’s ability to swallow before allowing the patient to attempt liquids or solid foods.
- Inform the patient that he or she may experience some throat soreness and hoarseness. Instruct patient to treat throat discomfort with lozenges and warm gargles when the gag reflex returns.
- Monitor vital signs and compare with baseline values every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Emergency resuscitation equipment should be readily available if the vocal cords become spastic after intubation.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hyperventilation, palpitations, nausea, or vomiting.
- Observe the patient for hemoptysis, difficulty breathing, cough, air hunger, excessive coughing, pain, or absent breathing sounds over the affected area. Report any symptoms to the HCP.
- Evaluate the patient for symptoms indicating the development of pneumothorax, such as dyspnea, tachypnea, anxiety, decreased breathing sounds, or restlessness. A chest x-ray may be ordered to check for the presence of this complication.
- Evaluate the patient for symptoms of empyema, such as fever, tachycardia, malaise, or elevated white blood cell count.
- Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- **Nutritional considerations:** Malnutrition is commonly seen in patients with severe respiratory disease for numerous reasons including fatigue, lack of appetite, and gastrointestinal distress. Adequate intake of vitamins A and C are also important to prevent pulmonary infection and to decrease the extent of lung tissue damage.
- Recognize anxiety related to test results, and be supportive of impaired activity related to perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Lung Association (www.lungusa.org).
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of smoking cessation programs, as appropriate. Inform the patient with abnormal findings of the importance of medical follow-up.
and suggest ongoing support resources to assist in coping with chronic illness and possible early death. Answer any questions or address any concerns voiced by the patient or family.

» Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

» Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include arterial/alveolar oxygen ratio, biopsy lung, blood gases, bronchoscopy, complete blood count, CT thoracic, relevant cultures (fungal, mycobacteria, sputum, throat, viral), gallium scan, gram/acid-fast stain, lung perfusion scan, lung ventilation scan, MRI chest, mediastinoscopy, pleural fluid analysis, pulmonary function tests, and TB tests.

- Refer to the Immune and Respiratory System tables at the end of the book for related tests by body system.

---

**Cytology, Urine**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Urine (180 mL for an adult or at least 10 mL for a child) collected in a clean wide-mouth plastic container.

**REFERENCE VALUE:** (Method: Microscopic examination) No abnormal cells or inclusions seen.

**DESCRIPTION:** Cytology is the study of the origin, structure, function, and pathology of cells. In clinical practice, cytological examinations are generally performed to detect cell changes resulting from neoplastic or inflammatory conditions. Cells from the epithelial lining of the urinary tract can be found in the urine. Examination of these cells for abnormalities is useful with suspected infection, inflammatory conditions, or malignancy.

**INDICATIONS:**

- Assist in the diagnosis of urinary tract diseases, such as cancer, cytomegalovirus infection, and other inflammatory conditions.
RESULT:

**Positive findings in:**
- Cancer of the urinary tract
- Cytomegalic inclusion disease
- Inflammatory disease of the urinary tract

**Negative findings in:** N/A

**CRITICAL VALUES:**
It is essential that critical diagnoses be communicated immediately and directly from the pathologist to the health care provider (HCP). A listing of these diagnoses varies from facility to facility.

**INTERFERING FACTORS:** N/A

---

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to identify the presence of neoplasms of the urinary tract and assist in the diagnosis of urinary tract infections.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s genitourinary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Note any recent procedures that can interfere with test results.
- Review the procedure with the patient. If a catheterized specimen is to be collected, explain this procedure to the patient and obtain a catheterization tray. Address concerns about pain and explain that there may be some discomfort during the catheterization.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date and time of collection, method of specimen collection, and any medications the patient has taken that may interfere with test results (e.g., antibiotics).

**Clean-Catch Specimen:**
- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

**Pediatric Urine Collector:**
- Put on gloves. Appropriately cleanse the genital area, and allow the area to dry. Remove the covering over the adhesive strips on the collector bag and apply over the genital area. Diaper the child. After obtaining the specimen, place the entire collection bag in a sterile urine container.

**Indwelling Catheter:**
- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection.
Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

**Urinary Catheterization:**
Place female patient in lithotomy position or male patient in supine position. Using sterile technique, open the straight urinary catheterization kit and perform urinary catheterization. Place the retained urine in a sterile specimen container.

**Suprapubic Aspiration:**
Place the patient in supine position. Cleanse the area with antiseptic, and drape with sterile drapes. A needle is inserted through the skin into the bladder. A syringe attached to the needle is used to aspirate the urine sample. The needle is then removed and a sterile dressing is applied to the site. Place the sterile sample in a sterile specimen container.

Do not collect urine from the pouch from a patient with a urinary diversion (e.g., ileal conduit). Instead perform catheterization through the stoma.

**General:**
Promptly transport the specimen to the laboratory for processing and analysis. If a delay in transport is expected, add an equal volume of 50% alcohol to the specimen as a preservative.

**POST-TEST:**
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
Instruct the patient to resume usual medication as directed by the HCP.
Instruct the patient to report symptoms such as pain related to tissue inflammation, pain or irritation during void, bladder spasms, or alterations in urinary elimination.
Observe for signs of inflammation if the specimen is obtained by suprapubic aspiration.
Administer antibiotic therapy as ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle.
Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Educate the patient regarding access to counseling services.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
Related tests include biopsy kidney, bladder cancer markers, cystoscopy, CMV IgG and IgM, PAP smear, UA, and US bladder.
Refer to the Genitourinary and Immune System tables at the end of the book for related tests by body system.
Cytomegalovirus, Immunoglobulin G and Immunoglobulin M

**SYNONYM/ACRONYM:** CMV.

**SPECIMEN:** Serum (1 mL) collected in a plain red-top tube.

**REFERENCE VALUE:** (Method: Indirect fluorescent antibody) Negative or less than a fourfold increase in titer.

**DESCRIPTION:** Cytomegalovirus (CMV) is a double-stranded DNA herpesvirus. The incubation period for primary infection is 4 to 8 wk. Transmission may occur by direct contact with oral, respiratory, or venereal secretions and excretions. CMV infection is of primary concern in pregnant or immunocompromised patients or patients who have recently received an organ transplant. Blood units are sometimes tested for the presence of CMV if patients in these high-risk categories are the transfusion recipients. CMV serology is part of the TORCH (toxoplasmosis, other [congenital syphilis and viruses], rubella, CMV, and herpes simplex type 2) panel used to test pregnant women. CMV, as well as these other infectious agents, can cross the placenta and result in congenital malformations, abortion, or stillbirth. The presence of immunoglobulin (Ig) M antibodies indicates acute infection. The presence of IgG antibodies indicates current or past infection.

**RESULT:**
- **Positive findings in:**
  - CMV infection

**Negative findings in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- False-positive results may occur in the presence of rheumatoid factor.
- False-negative results may occur if treatment was begun before antibodies developed or if the test was done less than 6 days after exposure to the virus.

**INDICATIONS:**
- Assist in the diagnosis of congenital CMV infection in newborns
- Determine susceptibility, particularly in pregnant women, immunocompromised patients, and patients who recently have received an organ transplant
- Screen blood for high-risk-category transfusion recipients

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of CMV infection.
- Obtain a history of the patient’s complaints and history of exposure. Obtain
a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient’s immune and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that multiple specimens may be required. Any individual positive result should be repeated in 7 to 14 days to monitor a change in titer. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient in isolation precautions during time of communicability or contagion.
- Emphasize the need to return to have a convalescent blood sample taken in 7 to 14 days.
- Warn the patient that there is a possibility of false-negative or false-positive results.
- Recognize anxiety related to test results if the patient is pregnant, and offer support. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include $\beta_2$-microglobulin, bronchoscopy, chlamydia group antibody, culture viral, cytology urine, HIV-1/2 antibodies, PAP smear, rubella antibody, and Toxoplasma antibody.
- Refer to the Immune and Reproductive System tables at the back of the book for related tests by body system.
SYNONYM/ACRONYM: Dimer, fibrin degradation fragment.

SPECIMEN: Plasma (1 mL) collected in a completely filled blue-top (sodium citrate) tube.

REFERENCE VALUE: (Method: Latex semiquantitative screen or quantitative enzyme-linked immunosorbent assay [ELISA])

*Semiquantitative:* No fragments detected
*Quantitative:* Less than 250 ng/mL

DESCRIPTION: The d-dimer is an asymmetric carbon compound formed by a cross-link between two identical fibrin molecules. The test is specific for secondary fibrinolysis because the cross-linkage occurs with fibrin and not fibrinogen. A positive test is presumptive evidence of disseminated intravascular coagulation (DIC).

INDICATIONS:
- Assist in the detection of DIC and deep venous thrombosis (DVT)
- Assist in the evaluation of myocardial infarction (MI) and unstable angina
- Assist in the evaluation of possible veno-occlusive disease associated with sequelae of bone marrow transplant
- Assist in the evaluation of pulmonary embolism

RESULT:
The sensitivity and specificity of the assay varies among test kits and between test methods (e.g., latex vs. ELISA).

*Increased in:*

d-Dimers are formed in inflammatory conditions where plasminogen activators carry out its fibrinolytic action on a fibrin clot.

- Arterial or venous thrombosis
- DVT
- DIC
- Neoplastic disease
- Pre-eclampsia
- Pregnancy (late and postpartum)
- Pulmonary embolism
- Recent surgery (within 2 days)
- Secondary fibrinolysis

*Decreased in:* N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- High rheumatoid factor titers can cause a false-positive result.
- Increased CA 125 levels can cause a false-positive result.
- Drugs that may cause an increase in plasma d-dimer include those administered for antiplatelet therapy.
- Drugs that may cause a decrease in plasma d-dimer include pravastatin and warfarin.
- Placement of tourniquet for longer than 1 min can result in venous stasis and changes in the concentration of plasma proteins to be measured. Platelet activation may also occur under these conditions, causing erroneous results.
- Vascular injury during phlebotomy can activate platelets and...
coagulation factors, causing erroneous results.
- Hemolyzed specimens must be rejected because hemolysis is an indication of platelet and coagulation factor activation.
- Incompletely filled tubes contaminated with heparin or clotted specimens must be rejected.
- Icteric or lipemic specimens interfere with optical testing methods, producing erroneous results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used in the evaluation of acute MI and DIC and to detect DVT.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of hematological diseases and recent surgery.
- Obtain a history of the patient’s cardiovascular, hematopoietic, and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

INSTRUCT the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL blue-top tube. Fill the tube completely. Important note: Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It is important to ask the laboratory which concentration it recommends, because each concentration will have its own specific reference range.
- When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and nonadditive red-top tubes. When coagulation testing is the only work to be done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with tissue thromboplastin, which can falsely decrease values.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed samples stored in unopened tubes is that testing should be completed within 1 to 4 hr.

POST-TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include aPTT, alveoloar/arterial gradient, angiography pulmonary, antibodies anticardiolipin, AT-III, blood gases, coagulation factors, FDP, fibrinogen, lactic acid, lung perfusion scan, plasminogen, platelet count, plethysmography, protein S, PT/INR, US venous doppler extremity studies, and venography lower extremity studies.
- Refer to the Cardiovascular, Hematopoietic, and Respiratory System tables at the end of the book for related tests by body system.

**Dehydroepiandrosterone Sulfate**

**SYNONYM/ACRONYM:** DHEAS.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in lavender-top (EDTA) tube is also acceptable.

**REFERENCE VALUE:** (Method: Radioimmunoassay)

**DESCRIPTION:** Dehydroepiandrosterone sulfate (DHEAS) is the major precursor of 17-ketosteroids. DHEAS is a metabolite of DHEA, the principal adrenal androgen. DHEAS is primarily synthesized in the adrenal gland, with a small amount secreted by the testes. DHEAS is a weak androgen and can be converted into more potent androgens (e.g., testosterone) as well as estrogens (e.g., estradiol). It is secreted in concert with cortisol, under the control of adrenocorticotrophic hormone (ACTH) and prolactin. Excessive production causes masculinization in women and children. DHEAS has replaced measurement of urinary 17-ketosteroids in the estimation of adrenal androgen production.

**INDICATIONS:**
- Assist in the evaluation of androgen excess, including congenital adrenal hyperplasia, adrenal tumor, and Stein-Leventhal syndrome
- Evaluate women with infertility, amenorrhea, or hirsutism

**RESULT:**
- Increased in:
  - Anovulation
  - Cushing’s syndrome
  - Ectopic ACTH-producing tumors
  - Hirsutism
  - Hyperprolactinemia
  - Polycystic ovary (Stein-Leventhal syndrome)
  - Virilizing adrenal tumors

- Decreased in:
  - Addison’s disease
  - Adrenal insufficiency (primary or secondary)
  - Aging adults (Natural decline in production with age)
  - Hyperlipidemia
  - Pregnancy (Related to DHEAS produced by fetal adrenals and converted to estrogens in the placenta)
  - Psoriasis (Some potent topical medications used for long periods of time can result in chronic adrenal insufficiency)
  - Psychosis (Related to acute adrenal insufficiency)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase DHEAS levels include clomiphene,
corticotropin, danazol, DHEA, mifepristone, and nitrendipine.
• Drugs that may decrease DHEAS levels include carbamazepine, dexamethasone, ketoconazole, oral contraceptives, and phenytoin.
• Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when radioimmunoassay is the test method.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in identifying the cause for infertility, amenorrhea, or hirsutism.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, symptoms, phase of menstrual cycle, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ACTH, cortisol, prolactin, and testosterone.
- Refer to the Endocrine System table at the end of the book for related tests by body system.
Drugs of Abuse

Amphetamines Ethanol (Alcohol)
Barbiturates Opiates
Benzodiazepines Phencyclidine
Cannabinoids Tricyclic Antidepressants
Cocaine

SYNONYM/ACRONYM: Amphetamines, barbiturates, benzodiazepines (tranquilizers), cannabinoids (THC), cocaine, ethanol (alcohol, ethyl alcohol, ETOH), phencyclidine (PCP), opiates (heroin), tricyclic antidepressants (TCA)

SPECIMEN: For ethanol, serum (1 mL) collected in a red-top tube; plasma (1 mL) collected in gray-top (sodium fluoride/potassium oxalate) tube is also acceptable. For drug screen, urine (15 mL) collected in a clean plastic container. Gastric contents (20 mL) may also be submitted for testing.

Workplace drug-screening programs, because of the potential medicolegal consequences associated with them, require collection of urine and blood specimens using a chain of custody protocol. The protocol provides securing the sample in a sealed transport device in the presence of the donor and a representative of the donor’s employer, such that tampering would be obvious. The protocol also provides a written document of specimen transfer from donor to specimen collection personnel, to storage, to analyst, and to disposal.

REFERENCE VALUE: (Method: Spectrophotometry for ethanol; immunoassay for drugs of abuse)

Ethanol: None detected
Drug screen: None detected

DESCRIPTION: Drug abuse continues to be one of the most significant social and economic problems in the United States. The National Institute for Drug Abuse (NIDA) has identified opiates, cocaine, cannabinoids, amphetamines, and phencyclidines (PCPs) as the most commonly abused illicit drugs. Alcohol is the most commonly encountered legal substance of abuse. Chronic alcohol abuse can lead to liver disease, high blood pressure, cardiac disease, and birth defects.

INDICATIONS:
- Differentiate alcohol intoxication from diabetic coma, cerebral trauma, or drug overdose
- Investigate suspected drug abuse
- Investigate suspected drug overdose
- Investigate suspected noncompliance with drug or alcohol treatment program
- Monitor ethanol levels when administered to treat methanol intoxication
- Routine workplace screening
RESULT:
A urine screen merely identifies the presence of these substances in urine; it does not indicate time of exposure, amount used, quality of the source used, or level of impairment. Positive screens should be considered presumptive. Drug-specific confirmatory methods should be used to investigate questionable results of a positive urine screen.

CRITICAL VALUES:
Note and immediately report to the health care provider (HCP) any critically increased values and related symptoms.

The legal limit for ethanol intoxication varies from state to state, but in most states greater than 80 mg/dL (0.08 G%) is considered impaired for driving. Levels greater than 300 mg/dL are associated with amnesia, vomiting, double vision, and hypothermia. Levels of 400 to 700 mg/dL are associated with coma and may be fatal. Possible interventions for ethanol toxicity include administration of tap water or 3% sodium bicarbonate lavage, breathing support, and hemodialysis (usually indicated only if levels exceed 300 mg/dL).

Barbiturate and benzodiazepine intoxication causes central nervous system (CNS) depression, which may progress to respiratory failure, hypotension, coma, and death. Do not induce emesis because of the risk of aspiration. Possible interventions include airway protection, administration of oxygen, gastric lavage with water or saline (up to 24 hr after ingestion), administration of activated charcoal, and monitoring CNS depression.

PCP intoxication causes a variety of symptoms depending on the stage of intoxication. Stage I includes psychiatric signs, muscle spasms, fever, tachycardia, flushing, small pupils, salivation, nausea, and vomiting. Stage II includes stupor, convulsions, hallucinations, increased heart rate, and increased blood pressure. Stage III includes further increases of heart rate and blood pressure that may culminate in cardiac and respiratory failure. Possible interventions may include providing respiratory support, administration of activated charcoal with a cathartic such as sorbitol, gastric lavage and suction, administration of IV nutrition and electrolytes, and acidification of the urine to promote PCP excretion.

Cocaine intoxication causes short-term symptoms of CNS stimulation, hypertension, tachypnea, mydriasis, and tachycardia. Possible interventions include emesis (if orally ingested and if the patient has a gag reflex and normal CNS function), gastric lavage (if orally ingested), whole-bowel irrigation (if packs of the drug were ingested), airway protection, cardiac support, and administration of diazepam or phenobarbital for

### Cutoff Concentrations for Drugs of Abuse Recommended by NIDA

convulsions. The use of β-blockers is contraindicated.

Amphetamine intoxication causes psychoses, tremors, convulsions, insomnia, tachycardia, dysrhythmias, impotence, cerebrovascular accident, and respiratory failure. Possible interventions include emesis (if orally ingested and if the patient has a gag reflex and normal CNS function), administration of activated charcoal followed by magnesium citrate cathartic; acidification of the urine to promote excretion, and administration of liquids to promote urinary output.

Heroin is an opiate that at toxic levels causes bradycardia, flushing, itching, hypotension, hypothermia, and respiratory depression. Possible interventions include airway protection and the administration of naloxone (Narcan).

TCA intoxication causes confusion, agitation, hallucinations, seizures, dysrhythmias, hyperthermia, dilation of the pupils, and coma. Possible interventions may include administration of activated charcoal; gastric lavage with saline; IV administration of physostigmine (to counteract coma, hypertension, respiratory depression, and seizures); administration of bicarbonate (to control dysrhythmia); administration of propranolol, lidocaine, or phenytoin to control convulsions; and monitoring cardiac function.

INTERFERING FACTORS:
- Codeine-containing cough medicines and antidiarrheal preparations, as well as ingestion of large amounts of poppy seeds, may produce a false-positive opiate result.
- Adulterants such as bleach or other strong oxidizers can produce erroneous urine drug screen results.
- Alcohol is a volatile substance, and specimens should be stored in a tightly stoppered container to avoid falsely decreased values.
Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date, and time of collection. For alcohol level, use a non–alcohol-containing solution to cleanse the venipuncture site before specimen collection. Perform a venipuncture, as appropriate. Cadaver blood is taken from the aorta. For a urine drug screen, instruct the patient to obtain a clean-catch urine specimen.

Remove the needle, and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

**Clean-Catch Specimen:**
- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.
- Follow the chain of custody protocol, if required. Monitor specimen collection, labeling, and packaging to prevent tampering. This protocol may vary by institution.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP who will discuss the results with the patient.
- Ensure that results are communicated to the proper individual, as indicated in the chain of custody protocol.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Educate the patient regarding access to counseling services. Provide support and information regarding detoxification programs, as appropriate. Provide contact information, if desired, for the National Institute on Drug Abuse (www.nida.nih.gov).
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Refer to the Therapeutic/Toxicology table at the end of the book for related tests.

**D-Xylose Tolerance Test**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Plasma (1 mL) collected in gray-top (fluoride/oxalate) tube and urine (10 mL from a 5-hr collection) in a clean amber plastic container.

**REFERENCE VALUE:** (Method: Spectrophotometry)
DESCRIPTION: The D-xylose tolerance test is used to screen for intestinal malabsorption of carbohydrates. D-Xylose is a pentose sugar not normally present in the blood in significant amounts. It is partially absorbed when ingested and normally passes unmetabolized in the urine.

INDICATIONS:
Assist in the diagnosis of malabsorption syndromes

RESULT:

*Increased in:* N/A

*Decreased in:* Conditions that involve defective mucosal absorption of carbohydrates and other nutrients.
- Amyloidosis
- Bacterial overgrowth *(Sugar is consumed by bacteria)*
- Eosinophilic gastroenteritis
- Lymphoma
- Non-tropical sprue (celiac disease, gluten-induced enteropathy)
- Parasitic infestations *(Giardia, schistosomiasis, hookworm)*
- Postoperative period after massive resection of the intestine
- Radiation enteritis
- Scleroderma
- Small bowel ischemia
- Tropical sprue
- Whipple’s disease
- Zollinger-Ellison syndrome

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs that may increase urine D-xylose levels include phenazopyridine.
- Drugs and substances that may decrease urine D-xylose levels include acetylsalicylic acid, aminosalicylic acid, arsenicals, colchicine, digitalis, ethionamide, gold, indomethacin, isocarboxazid, kanamycin, monoamine oxidase inhibitors, neomycin, and phenelzine.
- Poor renal function or vomiting may cause low urine values.
**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of intestinal malabsorption syndromes.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that activity will be restricted during the test.
- Obtain the pediatric patient’s weight to calculate dose of D-xylose to be administered. Inform the patient that blood specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Inform the patient that all urine for a 5-hr period must be saved. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device.
- Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- Numerous medications (e.g., acetylsalicylic acid, indomethacin, neomycin) interfere with the test and should be withheld, by medical direction, for 24 hr before testing.
- There are no fluid restrictions, unless by medical direction.
- The patient should fast for at least 12 hr before the test. In addition, the patient should refrain from eating foods containing pentose sugars such as fruits, jams, jellies, and pastries. Protocols may vary from facility to facility.

**INTRATEST:**
- Ensure that the patient has complied with dietary and medication restrictions; assure that food has been restricted for at least 12 hr prior to the procedure and medications have been withheld, by medical direction, for 24 hr prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

**Timed Specimen:**
- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 a.m. and 8 a.m., if possible. Remind the patient...
to remain supine and at rest throughout the duration of the test. Instruct the patient to collect all urine for a 5-hr period after administration of the D-xylose.

Adults are given a 25-g dose of D-xylose dissolved in 250 mL of water to take orally. The dose for pediatric patient is calculated by weight up to a maximum of 25 g. The patient should drink an additional 250 mL of water as soon as the D-xylose solution has been taken. Some adult patients with severe symptoms may be given a 5-g dose, but the test results are less sensitive at the lower dose.

If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage.

Blood samples are collected 1 hr postdose for pediatric patients and 2 hr postdose for adults.

Direct the patient to breathe normally and to avoid unnecessary movement. Perform a venipuncture, and collect the specimen in a 5-mL gray-top tube.

Include on the collection container’s label the amount of urine, test start and stop times, and ingestion of any foods or medications that could affect test results.

Promptly transport the specimens to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume usual medications, as directed by the HCP.

**Nutritional considerations:** Decreased D-xylose levels may be associated with gastrointestinal disease. Nutritional therapy may be indicated in the presence of malabsorption disorders. Encourage the patient, as appropriate, to consult with a qualified nutrition specialist to plan a lactose- and gluten-free diet. This dietary planning is complex because patients are often malnourished and have related nutritional problems.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Offer support to help the patient and/or caregiver cope with the long-term implications of a chronic disorder and related lifestyle changes. Educate the patient regarding access to counseling services, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include biopsy intestine, chloride sweat, fecal analysis, fecal fat, gastric emptying scan, lactose tolerance, ova and parasite, and RAIU.
- Refer to the Gastrointestinal System table at the back of the book for related tests by body system.
**Echocardiography**

**SYNONYM/ACRONYM:** Doppler echo, Doppler ultrasound of the heart, echo.

**AREA OF APPLICATION:** Chest/thorax.

**CONTRAST:** Can be done with or without noniodinated contrast medium (microspheres).

**DESCRIPTION:** Echocardiography, a noninvasive ultrasound (US) procedure, uses high-frequency sound waves of various intensities to assist in diagnosing cardiovascular disorders. The procedure records the echoes created by the deflection of an ultrasonic beam off the cardiac structures and allows visualization of the size, shape, position, thickness, and movement of all four valves, atria, ventricular and atria septa, papillary muscles, chordae tendineae, and ventricles. This study can also determine blood-flow velocity and direction and the presence of pericardial effusion during the movement of the transducer over areas of the chest. Electrocardiography and phonocardiography can be done simultaneously to correlate the findings with the cardiac cycle. These procedures can be done at the bedside or in a specialized department, health care provider’s (HPC’s) office, or clinic.

Included in the study are the M-mode method, which produces a linear tracing of timed motions of the heart, its structures, and associated measurements over time; and the two-dimensional method, using real-time Doppler color-flow imaging with pulsed and continuous-wave Doppler spectral tracings, which produces a cross-section of the structures of the heart and their relationship to one another, including changes in the coronary vasculature, velocity and direction of blood flow, and areas of eccentric blood flow. Doppler color-flow imaging may also be helpful in depicting the function of biological and prosthetic valves.

Cardiac contrast medium is used to aid in the diagnosis of intracardiac shunt and tricuspid valve regurgitation. The contrast agent is injected IV and outlines the chambers of the heart.

**INDICATIONS:**
- Detect atrial tumors (myxomas)
- Detect subaortic stenosis as evidenced either by displacement of the anterior atrial leaflet or by a reduction in aortic valve flow, depending on the obstruction
- Detect ventricular or atrial mural thrombi and evaluate cardiac wall motion after myocardial infarction
- Determine the presence of pericardial effusion, tamponade, and pericarditis
- Determine the severity of valvular abnormalities such as stenosis, prolapse, and regurgitation
- Evaluate congenital heart disorders
- Evaluate endocarditis
- Evaluate or monitor prosthetic valve function
- Evaluate the presence of shunt flow and continuity of the aorta and pulmonary artery
- Evaluate unexplained chest pain, electrocardiographic changes, and abnormal chest x-ray (e.g., enlarged cardiac silhouette)
• Evaluate ventricular aneurysms and/or thrombus
• Measure the size of the heart's chambers and determine if hypertrophic cardiomyopathy or congestive heart failure is present

RESULT:

Normal findings in:
• Normal appearance in the size, position, structure, and movements of the heart valves visualized and recorded in a combination of ultrasound modes; and normal heart muscle walls of both ventricles and left atrium, with adequate blood filling. Established values for the measurement of heart activities obtained by the study may vary by HCP and institution.

Abnormal findings in:
• Aneurysm
• Aortic valve abnormalities
• Cardiac neoplasm
• Cardiomyopathy
• Congenital heart defect
• Congestive heart failure
• Coronary artery disease
• Endocarditis
• Mitral valve abnormalities
• Myxoma
• Pericardial effusion, tamponade, and pericarditis
• Pulmonary hypertension
• Pulmonary valve abnormalities
• Septal defects
• Ventricular hypertrophy
• Ventricular or atrial mural thrombi

CRITICAL VALUES:
• Aneurysm
• Infection
• Obstruction
• Tumor with significant mass effect (Rare)

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

INTERFERING FACTORS:

Factors that may impair clear imaging:
• Incorrect placement of the transducer over the desired test site
• Retained barium from a previous radiological procedure
• Patients who are dehydrated, resulting in failure to demonstrate the boundaries between organs and tissue structures
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
• The presence of chronic obstructive pulmonary disease or use of mechanical ventilation, which increases the air between the heart and chest wall (hyperinflation) and can attenuate the ultrasound waves
• The presence of arrhythmias
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses cardiac function.
• Obtain a history of the patient's symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast mediums.
• Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy).
• Ensure that barium studies were performed at least 24 hr before this test.
Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements and nutraceuticals (see Appendix F).

Review the procedure with the patient. Address concerns about pain related to the procedure and explain that there should be no discomfort during the procedure. Inform the patient the procedure is performed in an US or cardiology department, usually by a HCP, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient to remove jewelry, and other metallic objects from the area to be examined.

There are no food or fluid restrictions, unless by medical direction.

**INTRATEST:**

- Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in a supine position on a flat table with foam wedges to help maintain position and immobilization.
- Expose the chest, and attach electrocardiogram leads for simultaneous tracings, if desired.
- Apply conductive gel to the chest. Place the transducer on the chest surface along the left sternal border, the subxiphoid area, suprasternal notch, and supraclavicular areas to obtain views and tracings of the portions of the heart. Scan the areas by systematically moving the probe in a perpendicular position to direct the ultrasound waves to each part of the heart.
- To obtain different views or information about heart function, position the patient on the left side and/or sitting up, or request that the patient breathe slowly or hold the breathe during the procedure. To evaluate heart function changes, the patient may be asked to inhale amyl nitrate (vasodilator).
- Administer contrast medium, if ordered. A second series of images is obtained.

**POST-TEST:**

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- When the study is completed, remove the gel from the skin.
- Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, atrial natriuretic peptide, BNP, blood gases, blood pool imaging, calcium, chest x-ray, cholesterol (total, HDL, LDL), CT cardiac scoring, CT thorax, CRP, CK and isoenzymes, echocardiography, echocardiography transesophageal, electrocardiogram,
Echocardiography, Transesophageal

**SYNONYM/ACRONYM:** Echo, TEE.

**AREA OF APPLICATION:** Chest/thorax.

**CONTRAST:** Can be done with or without noniodinated contrast medium (microspheres).

**DESCRIPTION:** Transesophageal echocardiography (TEE) is performed to assist in the diagnosis of cardiovascular disorders when noninvasive echocardiography is contraindicated or does not reveal enough information to confirm a diagnosis. Noninvasive echocardiography may be an inadequate procedure for patients who are obese, have chest wall structure abnormalities, or have chronic obstructive pulmonary disease (COPD). TEE provides a better view of the posterior aspect of the heart, including the atrium and aorta. It is done with a transducer attached to a gastroscope that is inserted into the esophagus. The transducer and the ultrasound (US) instrument allow the beam to be directed to the back of the heart. The echoes are amplified and recorded on a screen for visualization, and recorded on graph paper or videotape. The depth of the endoscope and movement of the transducer is controlled to obtain various images of the heart structures. TEE is usually performed during surgery; it is also used on patients who are in the intensive care unit, in whom the transmission of waves to and from the chest has been compromised and more definitive information is needed. The images obtained by TEE have better resolution than those obtained by routine transthoracic echocardiography because TEE uses higher frequency sound waves and offers closer proximity of the transducer to the cardiac structures. Cardiac contrast medium is used to improve the visualization of viable myocardial tissue within the heart.

**INDICATIONS:**
- Confirm diagnosis if conventional echocardiography does not correlate with other findings
- Detect and evaluate congenital heart disorders
- Detect atrial tumors (myxomas)
- Detect or determine the severity of valvular abnormalities and regurgitation
• Detect subaortic stenosis as evidenced by displacement of the anterior atrial leaflet and reduction in aortic valve flow, depending on the obstruction
• Detect thoracic aortic dissection and coronary artery disease (CAD)
• Detect ventricular or atrial mural thrombi and evaluate cardiac wall motion after myocardial infarction
• Determine the presence of pericardial effusion
• Evaluate aneurysms and ventricular thrombus
• Evaluate or monitor biological and prosthetic valve function
• Evaluate septal defects
• Measure the size of the heart’s chambers and determine if hypertrophic cardiomyopathy or congestive heart failure is present
• Monitor cardiac function during open heart surgery (most sensitive method for monitoring ischemia)
• Re-evaluate after inadequate visualization with conventional echocardiography as a result of obesity, trauma to or deformity of the chest wall, or lung hyperinflation associated with COPD

RESULT:

Normal findings in:
• Normal appearance of the size, position, structure, movements of the heart valves and heart muscle walls, and chamber blood filling; and no evidence of valvular stenosis or insufficiency, cardiac tumor, foreign bodies, or CAD. The established values for the measurement of heart activities obtained by the study may vary by health care provider (HCP) and institution.

Abnormal findings in:
• Aneurysm
• Aortic valve abnormalities
• CAD
• Cardiomyopathy

• Congenital heart defects
• Congestive heart failure
• Mitral valve abnormalities
• Myocardial infarction
• Myxoma
• Pericardial effusion
• Pulmonary hypertension
• Pulmonary valve abnormalities
• Septal defects
• Shunting of blood flow
• Thrombus
• Ventricular hypertrophy
• Ventricular or atrial mural thrombi

CRITICAL VALUES:
• Aneurysm
• Aortic dissection

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with significant esophageal pathology (procedure may cause bleeding)

Factors that may impair clear imaging:
• Incorrect placement of the transducer over the desired test site
• Retained barium from a previous radiological procedure
• Patients who are dehydrated, resulting in failure to demonstrate the boundaries between organs and tissue structures
• Laryngospasm, dysrhythmias, or esophageal bleeding
• Known upper esophageal pathology
• Conditions such as esophageal dysphagia and irradiation of the mediastinum
• The presence of COPD or use of mechanical ventilation, which increases the air between the heart and chest wall (hyperinflation) and can attenuate the ultrasound waves
• The presence of arrhythmias
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses cardiac function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast mediums.
- Obtain a history of the patient’s cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy).
- Ensure that barium studies were performed at least 24 hr before this test.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.
- Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort during insertion of the scope. Lidocaine is sprayed in the patient’s throat to reduce discomfort caused by the presence of the endoscope. Inform the patient that the procedure is performed in a US or cardiology department, usually by a HCP, and takes approximately 30 to 60 min.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

- Ensure that the patient has complied with dietary and fluid restriction for at least 8 hr prior to the procedure.
- Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Obtain and record the patient’s vital signs.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Ask patient as appropriate, to remove his or her dentures.
- Monitor pulse oximetry to determine oxygen saturation in sedated patients.
- Expose the chest, and attach electrocardiogram leads for simultaneous tracings, if desired.
- Spray or swab the patient’s throat with a local anesthetic, and place the oral bridge device in the mouth to prevent biting of the endoscope.
Place the patient in a left side-lying position on a flat table with foam wedges to help maintain position and immobilization. The pharyngeal area is anesthetized and the endoscope with the ultrasound device attached to its tip is inserted 30 to 50 cm to the posterior area of the heart, as in any esophagogastroduodenoscopy procedure.

Ask the patient to swallow as the scope is inserted. When the transducer is in place, the scope is manipulated by controls on the handle to obtain scanning that provides real-time images of the heart motion and recordings of the images for viewing. Actual scanning is usually limited to 15 min or until the desired number of image planes is obtained at different depths of the scope.

Administer contrast medium, if ordered. A second series of images is obtained.

POST-TEST:

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

Instruct the patient to resume usual diet and activity 4 to 6 hr after the test, as directed by the HCP.

Instruct patient to treat throat discomfort with lozenges and warm gargles when the gag reflex returns.

Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, atrial natriuretic peptide, BNP, blood gases, blood pool imaging, calcium, chest x-ray, cholesterol (total, HDL, LDL), CT cardiac scoring, CT thorax, CRP, CK and isoenzymes, echocardiography, electrocardiogram, exercise stress test, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isos, lipoprotein electrophoresis, lung perfusion scan, magnesium, MRI chest, MI infarct scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, pulse oximetry, sodium, triglycerides, and troponin.

Refer to the Cardiovascular System table in the back of the book for related tests by body system.
**DESCRIPTION:** The cardiac muscle consists of three layers of cells: the inner layer called the **endocardium**, the middle layer called the **myocardium**, and the outer layer called the **epicardium**. The systolic phase of the cardiac cycle reflects the contraction of the myocardium, whereas the diastolic phase takes place when the heart relaxes to allow blood to rush in. All muscle cells have a characteristic rate of contraction called **depolarization**. Therefore, the heart will maintain a predetermined heart rate unless other stimuli are received.

The monitoring of pulse and blood pressure evaluates only the mechanical activity of the heart. The electrocardiogram (ECG), a noninvasive study, measures the electrical currents or impulses that the heart generates during a cardiac cycle (see figure of a normal ECG at end of monograph). Electrical impulses travel through a conduction system beginning with the sinoatrial (SA) node and moving to the atrioventricular (AV) node via internodal pathways. From the AV node, the impulses travel to the bundle of His and onward to the right and left bundle branches. These bundles are located within the right and left ventricles. The impulses continue to the cardiac muscle cells by terminal fibers called **Purkinje fibers**. The ECG is a graphic display of the electrical activity of the heart, which is analyzed by time intervals and segments. Continuous tracing of the cardiac cycle activities is captured as heart cells are electrically stimulated, causing depolarization and movement of the activity through the cells of the myocardium.

The ECG study is completed by using 12 electrodes attached to the skin surface to obtain the total electrical activity of the heart. Each lead records the electrical potential between the limbs or between the heart and limbs. The ECG machine records and marks the 12 leads on the strip of paper in the machine in proper sequence, usually 6 in. of the strip for each lead. The ECG pattern, called a **heart rhythm**, is recorded by a machine as a series of waves, intervals, and segments, each of which pertains to a specific occurrence during the contraction of the heart. The ECG tracings are recorded on graph paper using vertical and horizontal lines for analysis and calculations of time, measured by the vertical lines (1 mm apart and 0.04 sec per line), and of voltage, measured by the horizontal lines (1 mm apart and 0.5 mV per 5 squares). A pulse rate can be calculated from the ECG strip to obtain the beats per minute. The P wave represents the depolarization of the atrial myocardium; the QRS complex represents the depolarization of the ventricular myocardium; the P-R interval represents the time from beginning of the excitation of the atrium to the beginning of the ventricular excitation; and the ST segment has no deflection from baseline, but in an abnormal state may be elevated or depressed. An abnormal rhythm is called an **arrhythmia**.

**INDICATIONS:**
- Assess the extent of congenital heart disease
- Assess the extent of myocardial infarction (MI) or ischemia, as indicated by abnormal ST segment, interval times, and amplitudes
- Assess the function of heart valves
- Assess global cardiac function
- Detect arrhythmias, as evidenced by abnormal wave deflections
• Detect pericarditis, shown by ST segment changes or shortened P-R interval
• Determine electrolyte imbalances, as evidenced by short or prolonged Q-T interval
• Determine hypertrophy of the chamber of the heart or heart hypertrophy, as evidenced by P or R wave deflections
• Evaluate and monitor cardiac pacemaker function
• Evaluate and monitor the effect of drugs, such as digitalis, antiarrhythmics, or vasodilating agents
• Monitor ECG changes during an exercise test
• Monitor rhythm changes during the recovery phase after an MI

RESULT:

Normal findings in:
• Normal heart rate according to age: range of 60 to 100 beats/min in adults
• Normal, regular rhythm and wave deflections with normal measurement of ranges of cycle components and height, depth, and duration of complexes as follows:
  - P wave: 0.12 sec or 3 small blocks with amplitude of 2.5 mm
  - Q wave: less than 0.04 mm
  - R wave: 5 to 27 mm amplitude, depending on lead
  - T wave: 1 to 13 mm amplitude, depending on lead
  - QRS complex: 0.12 sec or 3 small blocks
  - ST segment: 1 mm

Abnormal findings in:
• Arrhythmias.
• Atrial or ventricular hypertrophy.
• Bundle branch block.
• Electrolyte imbalances.
• MI or ischemia.
• Pericarditis.
• Pulmonary infarction.
• P wave: An enlarged P wave deflection could indicate atrial enlargement. An absent or altered P wave could suggest that the electrical impulse did not come from the SA node.
• P-R interval: An increased interval could imply a conduction delay in the AV node.
• QRS complex: An enlarged Q wave may indicate an old infarction; an enlarged deflection could indicate ventricular hypertrophy. Increased time duration may indicate a bundle branch block.
• ST segment: A depressed ST segment indicates myocardial ischemia. An elevated ST segment may indicate an acute MI or pericarditis. A prolonged ST segment may indicate hypocalcemia or hypokalemia (short segment).
• T wave: A flat or inverted T wave may indicate myocardial ischemia, infarction, or hypokalemia. A tall T wave may indicate hyperkalemia.

CRITICAL VALUES:
• Acute changes in ST elevation may indicate acute MI or pericarditis
• Bradycardia (less than 40 beats per min)
• PVCs greater than three in a row, pauses greater than 3 sec, or identified blocks
• Tachycardia (greater than 120 beats per min), supraventricular tachycardia, and ventricular tachycardia

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

INTERFERING FACTORS:
Factors that may impair the results of the examination:
• Anatomic variation of the heart (i.e., the heart may be rotated in both the horizontal and frontal planes)
• Distortion of cardiac cycles due to age, gender, weight, or a medical condition (e.g., infants, women [may exhibit slight ST segment depression], obese patients, pregnant patients, patients with ascites)

Access additional resources at davisplus.fadavis.com
- High intake of carbohydrates or electrolyte imbalances of potassium or calcium
- Improper placement of electrodes or inadequate contact between skin and electrodes because of insufficient conductive gel or poor placement, which can cause ECG tracing problems
- ECG machine malfunction or interference from electromagnetic waves in the vicinity
- Inability of the patient to remain still during the procedure, because movement, muscle tremor, or twitching can affect accurate test recording
- Increased patient anxiety, causing hyperventilation or deep respirations
- Medications such as barbiturates and digitalis
- Strenuous exercise before the procedure

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

No food, fluid, or medication restrictions exist, unless by medical direction.

**INTRATEST:**

- Ensure the patient has complied with pretesting preparations.
- Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline values.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place patient in a supine position. Expose and appropriately drape the chest, arms, and legs.
- Prepare the skin surface with alcohol and remove excess hair. Shaving may be necessary. Dry skin sites.
- Apply the electrodes in the proper position. When placing the six unipolar chest leads, place V₁ at the fourth intercostal space at the border of the right sternum, V₂ at the fourth intercostal space at the border of the left sternum, V₃ between V₂ and V₄, V₅ at the fifth intercostal space at the midclavicular line, V₆ at the left anterior axillary line at the level of V₄ horizontally, and V₇ at the level of V₄ horizontally and at the left midaxillary line. The wires are connected to the matched electrodes and the ECG machine. Chest leads (V₁, V₂, V₃, V₄, V₅, and V₆) record data from the horizontal plane of the heart.
- Place three limb bipolar leads (two electrodes combined for each) on the arms and legs. Lead I is the combination of two arm electrodes, lead II is the combination of right arm and left leg electrodes, and lead III is the combination of left arm and left leg electrodes. Limb leads (I, II, III, aVL, aVF, aVF).
aVF, and aVR) record data from the frontal plane of the heart.

The machine is set and turned on after the electrodes, grounding, connections, paper supply, computer, and data storage device are checked.

If the patient has any chest discomfort or pain during the procedure, mark the ECG strip indicating that occurrence.

**POST-TEST:**

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- When the procedure is complete, remove the electrodes and clean the skin where the electrode pads were applied.
- Evaluate the results in relation to previously performed ECGs. Denote cardiac rhythm abnormalities on the strip.
- Monitor vital signs and compare with baseline values. Protocols may vary from facility to facility.
- Instruct the patient to immediately notify a HCP of chest pain, changes in pulse rate, or shortness of breathe.
- Recognize anxiety related to the test results and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

**RELATED MONOGRAPHS:**

- Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, atrial natriuretic peptide, BNP, blood gases, blood pool imaging, calcium, chest x-ray, cholesterol (total, HDL, LDL), CT cardiac scoring, CT thorax, CRP, CK and isoenzymes, echocardiography, echocardiography transesophageal, exercise stress test, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isos, lipoprotein electrophoresis, lung perfusion scan, magnesium, MRI chest, MI infarct scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, pulse oximetry, sodium, triglycerides, and troponin.
- Refer to the Cardiovascular System table in the back of the book for related tests by body system.
Electroencephalography

**SYNONYM/ACRONYM:** Sonogram (for sleep disturbances), EEG.

**AREA OF APPLICATION:** Brain.

**CONTRAST:** None.

**DESCRIPTION:** Electroencephalography (EEG) is a noninvasive study that measures the brain’s electrical activity and records that activity on graph paper. These electrical impulses arise from the brain cells of the cerebral cortex. Electrodes, placed at 8 to 20 sites (or pairs of sites) on the patient’s scalp, transmit the different frequencies and amplitudes of the brain’s electrical activity to the EEG machine, which records the results in graph form on a moving paper strip. This procedure can evaluate responses to various stimuli, such as flickering light, hyperventilation, auditory signals, or somatosensory signals generated by skin electrodes. The procedure is usually performed in a room designed to eliminate electrical interference and minimize distractions. EEG can be done at the bedside, especially to confirm brain death. A health care provider (HCP) analyzes the waveforms. The test is used to detect epilepsy, intracranial abscesses, or tumors; to evaluate cerebral involvement due to head injury or meningitis; and to monitor for cerebral tissue ischemia during surgery when cerebral vessels must be occluded. EEG is also used to confirm brain death, which can be defined as absence of electrical activity in the brain. To evaluate abnormal EEG waves further, the patient may be connected to an ambulatory EEG system similar to a Holter monitor for the heart. Patients keep a journal of their activities and any symptoms that occur during the monitoring period.

**INDICATIONS:**
- Confirm brain death
- Confirm suspicion of increased intracranial pressure caused by trauma or disease
- Detect cerebral ischemia during endarterectomy
- Detect intracranial cerebrovascular lesions, such as hemorrhages and infarcts
- Detect seizure disorders and identify focus of seizure and seizure activity, as evidenced by abnormal spikes and waves recorded on the graph
- Determine the presence of tumors, abscesses, or infection
- Evaluate the effect of drug intoxication on the brain
- Evaluate sleeping disorders, such as sleep apnea and narcolepsy
- Identify area of abnormality in dementia

**RESULT:**

**Normal findings in:**
- Normal occurrences of alpha, beta, theta, and delta waves (rhythms varying depending on the patient’s age)
- Normal frequency, amplitude, and characteristics of brain waves
**Abnormal findings in:**
- Abscess
- Brain death
- Cerebral infarct
- Encephalitis
- Glioblastoma and other brain tumors
- Head injury
- Hypocalcemia or hypoglycemia
- Intracranial hemorrhage
- Meningitis
- Migraine headaches
- Narcolepsy
- Seizure disorders (grand mal, focal, temporal lobe, myoclonic, petit mal)
- Sleep apnea

**CRITICAL VALUES:**
- Abcess
- Brain death
- Head injury
- Hemorrhage
- Intracranial hemorrhage

Note and immediately report to the HCP abnormal results and related symptoms.

**INTERFERING FACTORS:**

**Factors that may impair the results of the examination:**
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Drugs and substances such as sedatives, anticonvulsants, anxiolytics, alcohol, and stimulants such as caffeine and nicotine
- Hypoglycemic or hypothermic states
- Hair that is dirty, oily, or sprayed or treated with hair preparations

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

Inform the patient that the procedure is performed to measure electrical activity of the brain.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast mediums.
- Obtain a history of the patient’s cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and assure the patient there is no discomfort during the procedure, but that, if needle electrodes are used, a slight pinch may be felt. Explain that electricity flows from the patient’s body, not into the body, during the procedure. Explain that the procedure reveals brain activity only, not thoughts, feelings, or intelligence. Inform the patient the procedure is performed in a neurodiagnostic department, usually by a HCP and support staff, and takes approximately 30 to 60 min.
- Inform the patient that he or she may be asked to alter breathing pattern; be asked to follow simple commands such as opening or closing eyes, blinking, or swallowing; be stimulated with bright light; or be given a drug to induce sleep during the study.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to clean the hair and to refrain from using hair sprays, creams, or solutions before the test.
- Instruct the patient to limit sleep to 5 hr for an adult and 7 hr for a child the night before the study. Young infants and children should not be allowed to nap before the study.
- Instruct the patient to eat a meal before the study and to avoid stimulants such as caffeine and nicotine for 8 hr prior to the procedure. Under medical direction, the patient should avoid sedatives, anticonvulsants,
anxiolytics, and alcohol for 24 to 48 hr before the test.  
Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**
- Ensure the patient has complied with pretesting preparations. Ensure that caffeine-containing beverages were withheld for 8 hr before the procedure, and that a meal was ingested before the study.
- Ensure that all substances with the potential to interfere with test results were withheld for 24 to 48 hr before the test.
- Ensure that the patient is able to relax; report any extreme anxiety or restlessness.
- Ensure that hair is clean and free of hair sprays, creams, or solutions.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position in a bed or in a semi-Fowler’s position on a recliner in a special room protected from any noise or electrical interferences that could affect the tracings.
- Remind the patient to relax and not to move any muscles or parts of the face or head. The HCP should be able to observe the patient for movements or other interferences through a window into the test room.
- The electrodes are prepared and applied to the scalp. Electrodes are placed in as many as 16 locations over the frontal, temporal, parietal, and occipital areas, and amplifier wires are attached. An electrode is also attached to each earlobe as grounding electrodes. At this time, a baseline recording can be made with the patient at rest.
- Recordings are made with the patient at rest and with eyes closed. Recordings are stopped about every 5 min to allow the patient to move. Recordings are also made during a drowsy and sleep period, depending on the patient’s clinical condition and symptoms.
- Procedures (e.g., stroboscopic light stimulation, hyperventilation to induce alkalosis, and sleep induction by administration of sedative to detect abnormalities that occur only during sleep) may be done to bring out abnormal electrical activity or other brain abnormalities.
- Observations for seizure activity are carried out during the study, and a description and time of activity is noted by the HCP.

**POST-TEST:**
- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- When the procedure is complete, remove electrodes from the hair and remove paste by cleansing with oil or witch hazel.
- If a sedative was given during the test, allow the patient to recover. Bedside rails are put in the raised position for safety.
- Instruct the patient to resume medications, as directed by the HCP.
- Instruct the patient to report any seizure activity.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include CSF analysis, CT brain, evoked brain potentials (SER, VER), MRI brain, and PET brain.
- Refer to the Musculoskeletal System table in the back of the book for related tests by body system.
Electromyography

SYNONYM/ACRONYM: Electrodagnostic study, neuromuscular junction testing, EMG.

AREA OF APPLICATION: Muscles.

CONTRAST: None.

DESCRIPTION: Electromyography (EMG) measures skeletal muscle activity during rest, voluntary contraction, and electrical stimulation. Percutaneous extracellular needle electrodes containing fine wires are inserted into selected muscle groups to detect neuromuscular abnormalities and measure nerve and electrical conduction properties of skeletal muscles. The electrical potentials are amplified, displayed on a screen in waveforms, and electronically recorded, similar to electrocardiography. Comparison and analysis of the amplitude, duration, number, and configuration of the muscle activity provide diagnostic information about the extent of nerve and muscle involvement in the detection of primary muscle diseases, including lower motor neuron, anterior horn cell, or neuromuscular junction diseases; defective transmission at the neuromuscular junction; and peripheral nerve damage or disease. Responses of a relaxed muscle are electrically silent, but spontaneous muscle movement such as fibrillation and fasciculation can be detected in a relaxed, denervated muscle. Muscle action potentials are detected with minimal or maximal muscle contractions. The differences in the size and numbers of activity potentials during voluntary contractions determine whether the muscle weakness is a disease of the striated muscle fibers or cell membranes (myogenic), or a disease of the lower motor neuron (neurogenic). Nerve conduction studies (electroneurography) are commonly done in conjunction with electromyography; the combination of the procedures is known as electromyoneurography. The examination’s major use lies in differentiating among the following disease classes: primary myopathy, peripheral motor neuron disease, and disease of the neuromuscular junction.

INDICATIONS:
- Assess primary muscle diseases affecting striated muscle fibers or cell membrane, such as muscular dystrophy or myasthenia gravis
- Detect muscle disorders caused by diseases of the lower motor neuron involving the motor neuron on the anterior horn of the spinal cord, such as anterior poliomyelitis, amyotrophic lateral sclerosis, amyotonia, and spinal tumors
- Detect muscle disorders caused by diseases of the lower motor neuron involving the nerve root, such as Guillain-Barré syndrome, herniated disc, or spinal stenosis
- Detect neuromuscular disorders, such as peripheral neuropathy

Access additional resources at davisplus.fadavis.com
caused by diabetes or alcoholism, and locate the site of the abnormality
• Determine if a muscle abnormality is caused by the toxic effects of drugs (e.g., antibiotics, chemotherapy) or toxins (e.g., Clostridium botulinum, snake venom, heavy metals)
• Differentiate between primary and secondary muscle disorders or between neuropathy and myopathy
• Differentiate secondary muscle disorders caused by polymyositis, sarcoidosis, hypocalcemia, thyroid toxicity, tetanus, and other disorders
• Monitor and evaluate progression of myopathies or neuropathies, including confirmation of diagnosis of carpal tunnel syndrome

RESULT:

Normal findings in:
• Normal muscle electrical activity during rest and contraction states

Abnormal findings in:
• Evidence of neuromuscular disorders or primary muscle disease (Note: findings must be correlated with the patient's history, clinical features, and results of other neurodiagnostic tests):
  Amyotrophic lateral sclerosis
  Bell's palsy
  Beriberi
  Carpal tunnel syndrome
  Dermatomyositis
  Diabetic peripheral neuropathy
  Eaton-Lambert syndrome
  Guillain-Barré syndrome
  Multiple sclerosis
  Muscular dystrophy
  Myasthenia gravis
  Myopathy
  Polymyositis
  Radiculopathy
  Traumatic injury

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with extensive skin infection
• Patients receiving anticoagulant therapy
• Patients with an infection at the sites of electrode placement

Factors that may impair the results of the examination:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Age-related decreases in electrical activity
• Medications such as muscle relaxants, cholinergics, and anticholinergics
• Improper placement of surface or needle electrodes

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient the procedure is performed to measure electrical activity of the muscles.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast mediums.
• Obtain a history of the patient’s musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Address concerns about pain related to the procedure and warn the patient the procedure may be uncomfortable, but an analgesic or sedative will be administered. Inform the patient that as many as 10 electrodes may be inserted at various locations on the body. Inform the patient the procedure is performed in a special laboratory by
a health care provider (HCP) and takes approximately 1–3 hr to complete, depending on the patient’s condition. Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. Assess for the ability to comply with directions given for exercising during the test. Instruct the patient to remove jewelry and other metallic objects from the area to be examined. Under medical direction, the patient should avoid muscle relaxants, cholinergics, and anticholinergics for 3 to 6 days before the test. Instruct the patient to refrain from smoking and drinking caffeine-containing beverages for 3 hr before the procedure. Protocols may vary from facility to facility. Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:
- Ensure the patient has refrained from smoking and drinking caffeine-containing beverages for 3 hr before the procedure.
- Ensure medications such as muscle relaxants, cholinergics, and anticholinergics have been withheld, as ordered.
- Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Ask the patient to remain very still and relaxed and to cooperate with instructions given to contract muscles during the procedure.
- Place the patient in a supine or sitting position depending on the location of the muscle to be tested. Ensure that the area or room is protected from noise or metallic interference that may affect the test results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer mild analgesic (adult) or sedative (children), as ordered, to promote a restful state before the procedure.
- Cleanse the skin thoroughly with alcohol pads, as necessary.

An electrode is applied to the skin to ground the patient, and then 24-gauge needles containing a fine-wire electrode are inserted into the muscle. The electrical potentials of the muscle are amplified, displayed on a screen, and electronically recorded. During the test, muscle activity is tested while the patient is at rest, during incremental needle insertion, and during varying degrees of muscle contraction. Ask the patient to alternate between a relaxed and a contracted muscle state, or to perform progressive muscle contractions while the potentials are being measured.

POST-TEST:
- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- When the procedure is complete, remove the electrodes and clean the skin where the electrode was applied.
- Monitor electrode sites for bleeding, hematoma, or inflammation.
- If residual pain is noted after the procedure, instruct the patient to apply warm compresses and to take analgesics, as ordered.
- Instruct the patient to resume usual diet, medication, and activity, as directed by the HCP.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
- Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include acetylcholine receptor antibody, biopsy muscle, CSF analysis, CT brain, CK, ENG, evoked brain potentials (SER, VER), MRI brain, plethysmography, and PET brain.
- Refer to the Musculoskeletal System table in the back of the book for related tests by body system.
Electromyography, Pelvic Floor Sphincter

SYNONYM/ACRONYM: Electrodiagnostic study, rectal electromyography.

AREA OF APPLICATION: Sphincter muscles.

CONTRAST: None.

DESCRIPTION: Pelvic floor sphincter electromyography, also known as rectal electromyography, is performed to measure electrical activity of the external urinary sphincter. This procedure, often done in conjunction with cystometry and voiding urography as part of a full urodynamic study, helps to diagnose neuromuscular dysfunction and incontinence.

INDICATIONS: Evaluate neuromuscular dysfunction and incontinence

RESULT:

Normal findings in:
• Normal urinary and anal sphincter muscle function; increased electromyographic signals during the filling of the urinary bladder and at the conclusion of voiding; absence of signals during the actual voiding; no incontinence.

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair the results of the examination:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Age-related decreases in electrical activity
• Medications such as muscle relaxants, cholinergics, and anticholinergics

Other considerations:
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure is performed to measure electrical activity of the pelvic floor muscles.
• Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensivities to latex, iodine, seafood, anesthetics, or contrast mediums.
• Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

This procedure is contraindicated for:
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Address concerns about pain related to the procedure. Warn the patient the procedure may be uncomfortable, but an analgesic or sedative will be administered. Assure the patient the pain is minimal during the catheter insertion. Inform the patient the procedure is performed in a special laboratory by a health care provider (HCP) and takes about 30 min to complete.

*Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. Instruct the patient to remove jewelry, and other metallic objects from the area to be examined.

Assess for ability to comply with directions given for exercising during the test. Under medical direction, the patient should avoid muscle relaxants, cholinergics, and anticholinergics for 3 to 6 days before the test.

Instruct the patient to refrain from smoking and drinking caffeine-containing beverages for 3 hr before the procedure. Protocols may vary from facility to facility.

*Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

**INTRATEST:**

Ensure the patient has complied with dietary, fluid, tobacco, and medication restrictions and pretesting preparations.

Record baseline vital signs.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Place the patient in a supine position on the examining table and place a drape over the patient, exposing the perineal area.

Ask the patient to remain very still and relaxed and to cooperate when instructed to contract muscles during the procedure.

Observe standard precautions, and follow the general guidelines in Appendix A.

Two skin electrodes are positioned slightly to the left and right of the perianal area and a grounding electrode is placed on the thigh.

If needle electrodes are used, they are inserted into the muscle surrounding the urethra.

Muscle activity signals are recorded as waves, which are interpreted for number and configurations in diagnosing urinary abnormalities.

An indwelling urinary catheter is inserted, and the bulbocavernosus reflex is tested; the patient is instructed to cough while the catheter is gently pulled.

Voluntary control is tested by requesting the patient to contract and relax the muscle. Electrical activity is recorded during this period of relaxation with the bladder empty.

The bladder is filled with sterile water at a rate of 100 mL/min while the electrical activity during filling is recorded.

The catheter is removed; the patient is then placed in a position to void and is asked to urinate and empty the full bladder. This voluntary urination is then recorded until completed. The complete procedure includes recordings of electrical signals before, during, and at the end of urination.

**POST-TEST:**

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Compare with baseline values. Protocols may vary from facility to facility.

Instruct the patient to increase fluid intake unless contraindicated.

If tested with needle electrodes, warn female patients to expect hematuria after the first voiding.

Advise the patient to report symptoms of urethral irritation, such as dysuria, persistent or prolonged hematuria, and urinary frequency.

Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss
the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include CT pelvis, cystometry, cystoscopy, cystourethrography voiding, IVP, and US bladder.
- Refer to the Genitourinary and Musculoskeletal System tables in the back of the book for related tests by body system.

---

**Electroneurography**

**SYNONYM/ACRONYM:** Electrodiagnostic study, nerve conduction study, ENG.

**AREA OF APPLICATION:** Muscles.

**CONTRAST:** None.

**DESCRIPTION:** Electroneurography (ENG) is performed to identify peripheral nerve injury, to differentiate primary peripheral nerve pathology from muscular injury, and to monitor response of the nerve injury to treatment. A stimulus is applied through a surface electrode over a nerve. After a nerve is electrically stimulated proximally, the time for the impulse to travel to a second or distal site is measured. Because the conduction study of a nerve can vary from nerve to nerve, it is important to compare the results of the affected side to those of the contralateral side. The results of the stimulation are shown on a monitor, but the actual velocity must be calculated by dividing the distance in meters between the stimulation point and the response point, by the time between the stimulus and response. Traumatic nerve transection, contusion, or neuropathy will usually cause maximal slowing of conduction velocity in the affected side compared with that in the normal side. A velocity greater than normal does not indicate a pathological condition. This test is usually performed in conjunction with electromyography in a combined test called electromyoneurography.
ELECTRONEUROGRAPHY

INDICATIONS:
Confirm diagnosis of peripheral nerve damage or trauma

RESULT:

Normal findings in:
• No evidence of peripheral nerve injury or disease. Variable readings depend on the nerve being tested. For patients age 3 yr and older, the maximum conduction velocity is 40 to 80 millisec; for infants and the elderly, the values are divided by 2.

Abnormal findings in:
• Carpal tunnel syndrome
• Diabetic neuropathy
• Guillain-Barré syndrome
• Herniated disk disease
• Muscular dystrophy
• Myasthenia gravis
• Poliomyelitis
• Tarsal tunnel syndrome
• Thoracic outlet syndrome

CRITICAL VALUES:  N/A

INTERFERING FACTORS:

Factors that may impair the results of the examination:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Age-related decreases in electrical activity
• Poor electrode conduction or failure to obtain contralateral values for comparison

Obtain a history of the patient’s complaints or symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast mediums.
Obtain a history of the patient’s neuromuscular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
Review the procedure with the patient. Address concerns about pain related to the procedure and inform the patient the procedure may be uncomfortable because of a mild electrical shock. Advise the patient that the electrical shock is brief and is not harmful. Inform the patient the procedure is performed in a special laboratory by a health care provider (HCP) and takes approximately 15 min to complete, but can take longer depending on the patient’s condition.
Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
There are no food, fluid, or medication restrictions, unless by medical direction.
Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
Place the patient in a supine or sitting position, depending on the location of the muscle to be tested.
Observe standard precautions, and follow the general guidelines in Appendix A.
Shave the extremity in the area to be stimulated, and cleanse the skin thoroughly with alcohol pads.

Access additional resources at davisplus.fadavis.com
Apply electrode gel and place a recording electrode at a known distance from the stimulation point. Measure the distance between the stimulation point and the site of the recording electrode in centimeters. Place a reference electrode nearby on the skin surface. The nerve is electrically stimulated by a shock-emitter device; the time between nerve impulse and electrical contraction, measured in millisecond (distal latency), is shown on a monitor. The nerve is also electrically stimulated at a location proximal to the area of suspected injury or disease. The time required for the impulse to travel from the stimulation site to location of the muscle contraction (total latency) is recorded in millisecond. Calculate the conduction velocity. The conduction velocity is converted to meters per second (m/sec) and computed using the following equation:

\[
\text{Conduction velocity (in m/sec)} = \frac{\text{distance (in m)}}{\text{total latency - distal latency}}
\]

POST-TEST:

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient. When the procedure is complete, remove the electrodes and clean the skin where the electrodes were applied. Monitor electrode sites for inflammation.

If residual pain is noted after the procedure, instruct the patient to apply warm compresses and to take analgesics, as ordered. Instruct the patient to resume usual diet, medication, and activity, as directed by the HCP. Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include acetylcholine receptor antibody, biopsy muscle, CK, EMG, and evoked brain potentials (SER, VER). Refer to the Musculoskeletal System table in the back of the book for related tests by body system.

---

**Eosinophil Count**

**SYNONYM/ACRONYM:** Eos count, total eosinophil count.

**SPECIMEN:** Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

**REFERENCE VALUE:** (Method: Manual count using eosinophil stain and hemocytometer or automated analyzer)

- **Absolute count:** 50 to 500/mm³
- **Relative percentage:** 1% to 4%
**DESCRIPTION:** Eosinophils are white blood cells whose function is phagocytosis of antigen-antibody complexes and response to allergy-inducing substances and parasites. Eosinophils have granules that contain histamine used to kill foreign cells in the body. Eosinophils also contain proteolytic substances that damage parasitic worms. The binding of histamine to receptor sites on cells results in smooth muscle contraction in the bronchioles and upper respiratory tract, constriction of pulmonary vessels, increased mucus production, and secretion of acid by the cells that line the stomach. Eosinophil counts can increase to greater than 30% of normal in parasitic infections; however, a significant percentage of children with visceral larva migrans infestations have normal eosinophil counts.

**INDICATIONS:**
Assist in the diagnosis of conditions such as allergies, parasitic infections, drug reactions, collagen diseases, Hodgkin’s disease, and myeloproliferative disorders

**RESULT:**

**Increased in:**
- Eosinophils are released and migrate to inflammatory sites in response to numerous environmental, chemical/drug, or immune-mediated triggers. T-cells, mast cells, and macrophages release cytokines like interleukin-3 (IL3), interleukin-5 (IL5), granulocyte/macrophage colony stimulating factor, and chemokines like the eotaxins, which can result in the activation of eosinophils.
- Addison’s disease (*Most commonly related to autoimmune destruction of adrenal glands*)
  - Allergy
  - Asthma
  - Cancer
  - Dermatitis
  - Drug reactions
  - Eczema
  - Hay fever
  - Hodgkin’s disease
  - Hypereosinophilic syndrome (rare and idiopathic)
  - Löeffler’s syndrome (*Pulmonary eosinophilia due to allergic reaction or infection from a fungus or parasite*)
  - Myeloproliferative disorders (*Related to abnormal changes in the bone marrow*)
  - Parasitic infection (visceral larva migrans)
  - Rheumatoid arthritis (*Possibly related to medications used in therapy*)
  - Rhinitis
  - Sarcoidosis
  - Splenectomy
  - Tuberculosis

**Decreased in:**
- Aplastic anemia (*Bone marrow failure*)
- Eclampsia (*Shift to the left; relative to significant production of neutrophils*)
- Infections (*Shift to the left; relative to significant production of neutrophils*)
- Stress (*Release of cortisol suppresses eosinophils*)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Numerous drugs and substances can cause an increase in eosinophil levels as a result of an allergic response or hypersensitivity
reaction. These include acetophenazine, allopurinol, aminosalicylic acid, ampicillin, butaperazine, capreomycin, carisoprodol, cephaloglycin, cephaloridine, cephalosporins, cephaiprin, cephradine, chloramphenicol, clindamycin, cloxacinil, dapsone, epicillin, erythromycin, fluorides, gold, imipramine, iodides, kanamycin, mafenamic acid, methicillin, methyldopa, minocycline, nalidixic acid, niridazole, nitrofurans (including nitrofurantoin), NSAIDs, nystatin, oxamniquine, penicillin, penicillin G, procainamide, ristocetin, streptokinase, streptomycin, tetracycline, triamterene, tryptophan, and viomycin.

- Drugs that can cause a decrease in eosinophil levels include acetylsalicylic acid, amphotericin B, corticotropin, desipramine, glucocorticoids, hydrocortisone, interferon, niacin, prednisone, and procainamide.
- Clotted specimens should be rejected for analysis.
- Specimens more than 4 hr old should be rejected for analysis.
- There is a diurnal variation in eosinophil counts. The count is lowest in the morning and continues to rise throughout the day until midnight. Therefore, serial measurements should be performed at the same time of day for purposes of continuity.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of conditions related to immune response, such as allergy or parasitic infection.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- **Nutritional considerations:** Consideration should be given to diet if food allergies are present.
Instruct the patient with an elevated eosinophil count to report any signs or symptoms of infection, such as fever. Instruct the patient with an elevated count to rest and take medications as prescribed, to increase fluid intake as appropriate, and to monitor temperature. Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include allergen-specific immunoglobulin E, biopsy bone marrow, blood gases, complete blood count, culture stool, ESR, fecal analysis, hypersensitivity pneumonitis screen, IgE, lung perfusion scan, ova and parasites, plethysmography, and PFT. Refer to the Hematopoietic, Immune, and Respiratory System tables at the end of the book for related tests by body system.

SYNONYM/ACRONYM: Free erythrocyte protoporphyrin (FEP).

SPECIMEN: Whole blood (1 mL) collected in lavender-top (EDTA) or green-top (heparin) tube.

REFERENCE VALUE: (Method: Fluorometry)

<table>
<thead>
<tr>
<th>Conventional Units</th>
<th>SI Units (Conventional Units × 0.0178)</th>

<tbody>
<tr>
<td>17–77 mcg/dL of packed cells</td>
<td>0.3–1.37 micromol/L of packed cells</td>
</tr>
</tbody>
</table>

DESCRIPTION: The free erythrocyte protoporphyrin test measures the concentration of protoporphyrin in red blood cells. Protoporphyrin comprises the predominant porphyrin in red blood cells, which combines with iron to form the heme portion of hemoglobin. Protoporphyrin converts to bilirubin, combines with albumin, and remains unconjugated in the circulation after hemoglobin breakdown. Increased amounts of protoporphyrin can be detected in erythrocytes, urine, and stool in conditions interfering with heme synthesis. Protoporphyrin is an autosomal dominant disorder in which increased amounts of protoporphyrin are secreted and excreted; the disorder is thought to be the result of an enzyme deficiency. Protoporphyrin causes photosensitivity and may lead to cirrhosis of the liver and cholelithiasis as a result of protoporphyrin deposits.
INDICATIONS:
• Assist in the diagnosis of erythropoietic protoporphyrias
• Assist in the differential diagnosis of iron deficiency in pediatric patients
• Evaluate lead poisoning

RESULT:

**Increased in:**
• Anemia of chronic disease
• Conditions with marked erythropoiesis (e.g., hemolytic anemias) *(Related to increased cell destruction)*
• Erythropoietic protoporphyria *(Related to abnormal increased secretion)*
• Iron-deficiency anemias *(Related to accumulation of protoporphyrin in the absence of available iron)*
• Lead poisoning *(Possibly related to inactivation of enzymes involved in iron binding or transfer)*
• Some sideroblastic anemias

**Decreased in:** N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may increase erythrocyte protoporphyrin levels include barbiturates, chlorpropamide, oral contraceptives, sulfomethane, and tolbutamide.
• The test is unreliable in infants less than 6 mo of age.

also used to differentiate disorders in heme and globin production.

Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient’s hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

*Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
• If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
• Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
• Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. Specimens should be protected from light.
• Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
• Promptly transport the specimen to the laboratory for processing and analysis.

**Nursing Implications and Procedure**

**PRETEST:**
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

**DESCRIPTION:** The erythrocyte sedimentation rate (ESR) is a measure of the rate of sedimentation of red blood cells (RBCs) in an anticoagulated whole blood sample over a specified period of time. The basis of the ESR test is the alteration of blood proteins by inflammatory and necrotic processes that cause the RBCs to stick together, become heavier, and rapidly settle at the bottom of a vertically held, calibrated tube over time. The most common promoter of rouleaux is an increase in circulating fibrinogen levels. In general, relatively little settling occurs in normal blood because normal RBCs do not form rouleaux (which increases their mass and rate of sedimentation) and would not stack together. The sedimentation rate is proportional to the size or mass of the falling RBCs and is inversely

Access additional resources at davisplus.fadavis.com
proportional to plasma viscosity. The test is a nonspecific indicator of disease but is fairly sensitive and is frequently the earliest indicator of widespread inflammatory reaction due to infection or autoimmune disorders. Prolonged elevations are also present in malignant disease. The ESR can also be used to monitor the course of a disease and the effectiveness of therapy. The most commonly used method to measure the ESR is the Westergren (or modified Westergren) method.

**INDICATIONS:**
- Assist in the diagnosis of acute infection, such as tuberculosis or tissue necrosis
- Assist in the diagnosis of acute inflammatory processes
- Assist in the diagnosis of chronic infections
- Assist in the diagnosis of rheumatoid or autoimmune disorders
- Assist in the diagnosis of temporal arthritis and polymyalgia rheumatica
- Monitor inflammatory and malignant disease

**RESULT:**

**Increased in:**
- Increased rouleaux formation is associated with increased levels of fibrinogen and/or production of cytokines and other acute phase reactant proteins in response to inflammation.
- Acute myocardial infarction
- Anemia (RBCs fall faster with increased plasma volume)
- Carcinoma
- Cat scratch fever (Bartonella henselae)
- Collagen diseases, including systemic lupus erythematosus (SLE)
- Crohn’s disease (Due to anemia or related to acute phase reactant proteins)
- Endocarditis
- Heavy metal poisoning (Related to anemia affecting size and shape of RBCs)
- Increased plasma protein level (RBCs fall faster with increased plasma viscosity)
- Infections (e.g., pneumonia, syphilis)
- Inflammatory diseases
- Lymphoma
- Lymphosarcoma
- Multiple myeloma (RBCs fall faster with increased plasma viscosity)

**Normal findings in:**
- Congestive heart failure
- Glucose-6-phosphate dehydrogenase deficiency
- Hemoglobin C disease
- Hypofibrinogenemia
- Polycythemia
- Sickle cell anemia
- Spherocytosis

**Decreased in:**
- Conditions resulting in high hemoglobin and RBC count
- Elevated blood glucose (Hyperglycemia in older patients can induce production of cytokines responsible for the inflammatory response; hyperglycemia related to insulin resistance can cause hepatocytes to shift protein synthesis from albumin to production of acute phase reactant proteins)

**CRITICAL VALUES:** N/A
ERYTHROCYTE SEDIMENTATION RATE

INTERFERING FACTORS:

- Some drugs cause an SLE-like syndrome that results in a physiological increase in ESR. These include anticonvulsants, hydrazine derivatives, nitrofurantoin, procainamide, and quinidine. Other drugs that may cause an increased ESR include acetylsalicylic acid, cephalothin, cepaparin, cyclosporin A, dextran, and oral contraceptives.
- Drugs that may cause a decrease in ESR include aurothiomalate, corticotropin, cortisone, and quinine.
- Menstruation may cause falsely increased test results.
- Prolonged tourniquet constriction around the arm may cause hemoconcentration and falsely low values.
- The Westergren and modified Westergren methods are affected by heparin, which causes a false elevation in values.
- Bubbles in the Westergren tube or pipette, or tilting the measurement column more than 3° from vertical, will falsely increase the values.
- Movement or vibration of the surface on which the test is being conducted will affect the results.
- Inaccurate timing will invalidate test results.
- Specimens that are clotted, hemolyzed, or insufficient in volume should be rejected for analysis.
- The test should be performed within 4 hr of collection when the specimen has been stored at room temperature; delays in testing may result in decreased values. If a delay in testing is anticipated, refrigerate the sample at 2°C to 4°C; stability at refrigerated temperature is reported to be extended up to 12 hr. Refrigerated specimens should be brought to room temperature before testing.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is a nonspecific indicator of inflammation.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of infectious, autoimmune, or neoplastic diseases.
- Obtain a history of the patient’s hematopoietic, immune, and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture. Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL gray-top (sodium citrate) tube if the Westergren method will be used.

Access additional resources at davisplus.fadavis.com
Collect the specimen in a 5-mL purple-top (EDTA) tube if the modified Westergren method will be used.

- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include antibodies, anticyclic citrullinated peptide, ANA, arthroscopy, arthrogram, blood pool imaging, BMD, bone scan, complete blood count, complete blood count, hematocrit, complete blood count, hemoglobin, complete blood count, RBC indices, complete blood count, RBC morphology, CT cardiac scoring, copper, CRP, D-dimer, exercise stress test, fibrinogen, glucose, iron, lead, MRI musculoskeletal, microorganism-specific serologies and related cultures, myocardial perfusion heart scan, radiography bone, RF, synovial fluid analysis, and troponin.
- Refer to the Cardiovascular, Hematopoietic, Immune, and Respiratory System tables at the end of the book for related tests by body system.

**SYNONYM/ACRONYM:** EPO.

**SPECIMEN:** Serum (2 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** (Method: Radioimmunoassay).

<table>
<thead>
<tr>
<th>Conventional Units</th>
<th>SI Units (Conventional Units × 1)</th>

</tbody>
</table>

**DESCRIPTION:** Erythropoietin (EPO) is a glycoprotein produced mainly by the kidney. Its function is to stimulate the bone marrow to make red blood cells (RBCs). EPO levels fall after removal of the kidney but do not disappear completely. It is thought that small amounts of EPO may be produced by the liver. Erythropoiesis is regulated by EPO and tissue Po2. When Po2 is normal, EPO levels decrease; when Po2 falls, EPO secretion occurs and EPO levels increase.
INDICATIONS:
• Assist in assessment of anemia of end-stage renal disease
• Assist in the diagnosis of EPO-producing tumors
• Evaluate the presence of rare anemias
• Monitor patients receiving EPO therapy

RESULT:
*Increased in:*
• After moderate bleeding in an otherwise healthy patient (*Loss of RBC stimulates production*)
• Anemias (*Low RBC count stimulates production*)
• Hepatoma (*EPO-producing tumors*)
• Kidney transplant rejection (15% of cases respond with an exaggerated secretion of EPO and a transient post-transplantation erythrocytosis)
• Nephroblastoma (*EPO-producing tumors*)
• Pheochromocytoma (*EPO-producing tumors*)
• Polycystic kidney disease (*EPO-producing tumors or cysts*)
• Pregnancy (*Anemia of pregnancy stimulates production*)
• Secondary polycythemia where low oxygen levels stimulate production (*high-altitude hypoxia, chronic obstructive pulmonary disease, pulmonary fibrosis*)

*Decreased in:*
• Chemotherapy (*Therapy can be toxic to the kidney*)
• Primary polycythemia (*Feedback loop response to elevated RBC count*)
• Renal failure (*Decreased production and excessive loss through excretion by damaged kidneys*)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may increase EPO levels include anabolic steroids.
• Drugs that may decrease EPO levels include amphotericin B, cisplatin, enalapril, estrogens, and theophylline.
• Blood transfusions may also decrease EPO levels.
• Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when radioimmunoassay is the test method.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used in the evaluation of anemias.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s hematopoietic and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Note any recent procedures that can interfere with test results.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain to the patient that there may be some discomfort during the venipuncture.
• Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• There are no food, fluid, or medication restrictions, unless by medical direction.

Access additional resources at davisplus.fadavis.com
**Esophageal Manometry**

**SYNONYM/ACRONYM:** Esophageal function study, esophageal acid study (Tuttle test), acid reflux test, Bernstein test (acid perfusion), esophageal motility study.

**AREA OF APPLICATION:** Esophagus.

**CONTRAST:** Done with or without noniodinated contrast medium.

**DESCRIPTION:** Esophageal manometry (EM) consists of a group of invasive studies performed to assist in diagnosing abnormalities of esophageal muscle function and esophageal structure. These studies measure esophageal pressure, the effects of gastric acid in the esophagus, lower esophageal sphincter pressure, and motility patterns that result during swallowing. EM can be used to document and quantify gastroesophageal reflux (GER). It is indicated when a patient is experiencing testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include biopsy bone marrow, BUN, complete blood count, complete blood count, hematocrit, complete blood count, hemoglobin, complete blood count, RBC count, complete blood count, RBC indices, complete blood count, RBC morphology and inclusions, CT renal, creatinine, creatinine clearance, ferritin, iron/TIBC, microalbumin, retrograde ureteropyelography, US kidney, and vitamin B₁₂.
- Refer to the Hematopoietic and Genitourinary System tables at the end of the book for related tests by body system.
ESOPHAGEAL MANOMETRY

**INDICATIONS:**
- Aid in the diagnosis of achalasia, evidenced by increased pressure in EM
- Aid in the diagnosis of chalasia in children, evidenced by decreased pressure in EM
- Aid in the diagnosis of esophageal scleroderma, evidenced by decreased pressure in EM
- Aid in the diagnosis of esophagitis, evidenced by decreased motility
- Aid in the diagnosis of GER, evidenced by low pressure in EM, decreased pH in acidity test, and pain in acid reflux and perfusion tests
- Differentiate between esophagitis or cardiac condition as the cause of epigastric pain
- Evaluate pyrosis and dysphagia to determine if the cause is GER or esophagitis

**RESULT:**

**Normal findings in:**
- Acid clearing: fewer than 10 swallows
- Acid perfusion: no GER
- Acid reflux: no regurgitation into the esophagus
- Bernstein test: negative
- Esophageal secretions: pH 5 to 6
- Esophageal sphincter pressure: 10 to 20 mm Hg

**Abnormal findings in:**
- Achalasia (sphincter pressure of 50 mm Hg)
- Chalasia
- Esophageal scleroderma
- Esophagitis

- GER (sphincter pressure of 0 to 5 mm Hg, pH of 1 to 3)
- Hiatal hernia
- Progressive systemic sclerosis (scleroderma)
- Spasms

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

*This procedure is contraindicated for:*
- Patients with unstable cardiopulmonary status, blood coagulation defects, recent gastrointestinal surgery, esophageal varices, or bleeding

*Factors that may impair the results of the examination:*
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Administration of medications (e.g., sedatives, antacids, anticholinergics, cholinergics, corticosteroids) that can change pH or relax the sphincter muscle, causing inaccurate results

*Other considerations:*
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the esophagus.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, and contrast mediums.

Access additional resources at davisplus.fadavis.com
Obtain a history of the patient’s respiratory and gastrointestinal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Note any recent barium or other radiological contrast procedures. Ensure that barium studies were performed more than 4 days before the EM.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.

Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort and gagging when the scope is inserted, but there are no complications resulting from the procedure and the throat will be anesthetized with a spray or swab. Inform the patient that he or she will not be able to speak during the procedure, but that breathing will not be affected. Inform the patient that the procedure is performed in an endoscopy suite by a health care provider (HCP) under local anesthesia, and takes approximately 30 to 45 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be started to allow for the infusion of a sedative or IV fluids.

Instruct the patient to remove dentures and eyewear.

Under medical direction, the patient should withhold medications for 24 hr before the study; special arrangements may be necessary for diabetic patients.

Instruct the patient to fast and restrict fluids for 6 to 8 hr prior to the procedure. Protocols may vary from facility to facility.

Obtain and record baseline vital signs.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

Ensure that the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations for at least 6 to 8 hr prior to the procedure.

Ensure the patient has removed dentures and eyewear prior to the procedure.

Avoid using morphine sulfate in patients with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions.

Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Insert an IV line and inject ordered sedation.

Spray or swab the oropharynx with a topical local anesthetic.

Provide an emesis basin for the increased saliva and encourage the patient to spit out saliva since the gag reflex may be impaired.

Monitor the patient for complications related to the procedure (e.g., aspiration of stomach contents into the lungs, dyspnea, tachypnea, adventitious sounds).

Suction the mouth, pharynx, and trachea, and administer oxygen as ordered.

Esophageal Manometry:

One or more small tubes are inserted through the nose into the esophagus and stomach.

A small transducer is attached to the ends of the tubes to measure...
lower esophageal sphincter pressure, intraluminal pressures, and regularity and duration of peristaltic contractions.

Instruct the patient to swallow small amounts of water or flavored gelatin.

**Esophageal Acid and Clearing (Tuttle Test):**
- With the tube in place, a pH electrode probe is inserted into the esophagus with Valsalva maneuvers performed to stimulate reflux of stomach contents into the esophagus.
- If acid reflux is absent, 100 mL of 0.1% hydrochloric acid is instilled into the stomach during a 3-min period, and the pH measurement is repeated.
- To determine acid clearing, hydrochloric acid is instilled into the esophagus and the patient is asked to swallow while the probe measures the pH.

**Acid Perfusion (Bernstein Test):**
- A catheter is inserted through the nose into the esophagus and the patient is asked to inform the HCP when pain is experienced.
- Normal saline solution is allowed to drip into the catheter at about 10 mL/min. Then hydrochloric acid is allowed to drip into the catheter.
- Pain experienced when the hydrochloric acid is instilled determines the presence of an esophageal abnormality. If no pain is experienced, symptoms are the result of some other condition.

**POST-TEST:**
- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Monitor the patient for signs of respiratory depression (less than 15 respirations/min) every 15 min for 2 hr. Resuscitation equipment should be available.
- Observe the patient for indications of perforation: painful swallowing with neck movement, substernal pain with respiration, shoulder pain, dyspnea, abdominal or back pain, cyanosis, and fever.
- Instruct the patient not to eat or drink until the gag reflex returns and then to eat lightly for 12 to 24 hr.
- Instruct the patient to resume usual activity, medication, and diet 24 hr after the examination or as tolerated, as directed by the HCP.
- Inform the patient to expect some throat soreness and possible hoarseness. Advise the patient to use warm gurgles, lozenges, or ice packs to the neck and to drink cool fluids to alleviate throat discomfort.
- Emphasize that any severe pain, fever, difficulty breathing, or expectoration of blood must be reported to the HCP immediately.
- Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ANA, barium swallow, biopsy skin, capsule endoscopy, chest x-ray, CT thoracic, esophagogastroduodenoscopy, fecal analysis, gastric emptying scan, GER scan, and upper GI series, lung perfusion scan, and mediastinoscopy.
- Refer to the Gastrointestinal and Respiratory System tables at the back of the book for related tests by body system.

Esophagogastroduodenoscopy

SYNONYM/ACRONYM: Esophagoscopy, gastroscopy, upper GI endoscopy, EGD.

AREA OF APPLICATION: Esophagus, stomach, and upper duodenum.

CONTRAST: Done without contrast.

DESCRIPTION: Esophagogastroduodenoscopy (EGD) allows direct visualization of the upper gastrointestinal (GI) tract mucosa, which includes the esophagus, stomach, and upper portion of the duodenum, by means of a flexible endoscope. The standard flexible fiberoptic endoscope contains three channels that allow passage of the instruments needed to perform therapeutic or diagnostic procedures, such as biopsies or cytology washings. The endoscope, a multichannel instrument, allows visualization of the GI tract linings, insufflation of air, aspiration of fluid, removal of foreign bodies by suction or by snare or forceps, and passage of a laser beam for obliteration of abnormal tissue or control of bleeding. Direct visualization yields greater diagnostic data than is possible through radiological procedures, and therefore EGD is rapidly replacing upper GI series as the diagnostic procedure of choice.

INDICATIONS:
- Evaluate the extent of esophageal injury after ingestion of chemicals
- Evaluate stomach or duodenum after surgical procedures
- Evaluate suspected gastric outlet obstruction
- Identify tissue abnormalities and obtain biopsy specimens
- Investigate the cause of dysphagia, dyspepsia, and epigastric pain

RESULT:

Normal findings in:
- Esophageal mucosa is normally yellow-pink. At about 9 in. from the incisor teeth, a pulsation indicates the location of the aortic arch. The gastric mucosa is orange-red and contains rugae. The proximal duodenum is reddish and contains a few longitudinal folds, whereas the distal duodenum has circular folds lined with villi. No abnormal structures or functions are observed in the esophagus, stomach, or duodenum.

Abnormal findings in:
- Acute and chronic gastric and duodenal ulcers
- Diverticular disease
- Duodenitis
- Esophageal varices
- Esophageal or pyloric stenosis
- Esophagitis or strictures
- Gastritis
- Hiatal hernia
- Mallory-Weiss syndrome
- Tumors (benign or malignant)
CRITICAL VALUES:
• Presence and location of acute GI bleed

Note and immediately report to the health care provider (HCP) positive results and related symptoms.

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients who have had surgery involving the stomach or duodenum, which can make locating the duodenal papilla difficult
• Patients with a bleeding disorder
• Patients with unstable cardiopulmonary status, blood coagulation defects, or cholangitis, unless the patient received prophylactic antibiotic therapy before the test (otherwise the examination must be rescheduled)
• Patients with unstable cardiopulmonary status, blood coagulation defects, known aortic arch aneurysm, large esophageal Zenker’s diverticulum, recent GI surgery, esophageal varices, or known esophageal perforation.

Factors that may impair clear imaging:
• Gas or food in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study
• Retained barium from a previous radiological procedure
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
• The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
• Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses the esophagus and upper GI tract.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast mediums.
• Obtain a history of the patient’s GI system, symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Note any recent barium or other radiological contrast procedures ordered. Ensure that barium studies are performed after this study.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
• Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.
• Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort, but that the throat will be anesthetized with a spray or swab. Inform the patient that he or she will not be able to speak during the procedure, but that breathing will not be affected. Inform the patient that the procedure is performed in a GI lab or radiology department, usually by a health care provider (HCP) and support staff, and takes approximately 30 to 60 min.
• Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
Explain that an IV line may be started to allow for the infusion of a sedative or IV fluids.
Inform the patient that a laxative and cleansing enema may be needed the day before the procedure, with cleansing enemas on the morning of the procedure, depending on the institution’s policy.
Inform the patient that dentures and eyewear will be removed before the test.
Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility.
Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure the patient has complied with dietary and medication restrictions and pretesting preparations for at least 8 hr prior to the procedure.
- Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Assess for completion of bowel preparation according to the institution’s procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.
- Obtain and record baseline vital signs.
- Start an IV line and administer ordered sedation.
- Spray or swab the oropharynx with a topical local anesthetic.
- Provide an emesis basin for the increased saliva and encourage the patient to spit out the saliva because the gag reflex may be impaired.
- Place the patient on an examination table in the left lateral decubitus position with the neck slightly flexed forward.
- The endoscope is passed through the mouth with a dental suction device in place to drain secretions. A side-viewing flexible, fiberoptic endoscope is advanced, and visualization of the GI tract is started.
- Air is insufflated to distend the upper GI tract, as needed. Biopsy specimens are obtained and/or endoscopic surgery is performed.
- Promptly transport the specimens to the laboratory for processing and analysis.
- At the end of the procedure, excess air and secretions are aspirated through the scope and the endoscope is removed.
- Remove the needle or catheter and apply a pressure dressing over the puncture site.

**POST-TEST:**

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
Observe the patient for indications of esophageal perforation (i.e., painful swallowing with neck movement, substernal pain with respiration, shoulder pain or dyspnea, abdominal or back pain, cyanosis, or fever).
Do not allow the patient to eat or drink until the gag reflex returns; then allow the patient to eat lightly for 12 to 24 hr.
Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered by the HCP. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated.
Protocols may vary from facility to facility.
Instruct the patient to resume usual activity and diet in 24 hr or as tolerated after the examination, as directed by the HCP.
Inform the patient that he or she may experience some throat soreness and hoarseness. Instruct patient to treat throat discomfort with lozenges and warm gargles when the gag reflex returns.
Inform the patient that any belching, bloating, or flatulence is the result of air insufflation and is temporary.
Instruct the patient that any severe pain, fever, difficulty breathing, or expectoration of blood must be immediately reported to the HCP.
Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include barium enema, barium swallow, capsule endoscopy, colonoscopy, CT abdomen, esophageal manometry, fecal analysis, gastric acid emptying scan, gastric acid stimulation test, gastrin stimulation, GI blood loss scan, H. pylori, MRI abdomen, proctosigmoidoscopy, US pelvis, upper GI series.
- Refer to the Gastrointestinal System table in the back of the book for related tests by body system.

---

**SYNONYM/ACRONYM:** E2.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

**REFERENCE VALUE:** (Method: Immunoassay)

---

**Evoked Brain Potentials**

**SYNONYM/ACRONYM:** EP studies, brainstem auditory evoked potentials (BAEP), brainstem auditory evoked responses (BAER).

**AREA OF APPLICATION:** Brain.

**CONTRAST:** None.

**DESCRIPTION:** Evoked brain potentials, also known as evoked potential (EP) responses, are electrophysiological studies performed to measure the brain’s electrical responses to various visual, auditory, and somatosensory stimuli. EP studies help diagnose lesions of the nervous system by evaluating the integrity of the visual, somatosensory, and auditory nerve pathways. Three response types are measured: visual evoked response (VER), auditory brainstem response (ABR), and somatosensory evoked response (SER). The stimuli activate the nerve tracts that connect the stimulated (receptor) area with the cortical (visual and somatosensory) or midbrain (auditory) sensory area. A number of stimuli are given and then responses are electronically displayed in waveforms, recorded, and
computer analyzed. Abnormalities are determined by a delay in time, measured in milliseconds, between the stimulus and the response. This is known as increased latency. VER provides information about visual pathway function to identify lesions of the optic nerves, optic tracts, and demyelinating diseases such as multiple sclerosis. ABR provides information about auditory pathways to identify hearing loss and lesions of the brainstem. SER provides information about the somatosensory pathways to identify lesions at various levels of the central nervous system (spinal cord and brain) and peripheral nerve disease. EP studies are especially useful in patients with problems and those unable to speak or respond to instructions during the test, because these studies do not require voluntary cooperation or participation in the activity. This allows collection of objective diagnostic information about visual or auditory disorders affecting infants and children, and allows differentiation between organic brain and psychological disorders in adults. EP studies are also used to monitor the progression of or the effectiveness of treatment for deteriorating neurological diseases such as multiple sclerosis.

**INDICATIONS:**

**VER (potentials):**
- Detect cryptic or past retrobulbar neuritis
- Detect lesions of the eye or optic nerves

**ABR (potentials):**
- Detect abnormalities or lesions in the brainstem or auditory nerve areas
- Detect brainstem tumors and acoustic neuromas
- Screen or evaluate neonates, infants, children, and adults for auditory problems
- EP studies may be indicated when a child falls below growth chart norms

**SER (potentials):**
- Detect multiple sclerosis and Guillain-Barré syndrome
- Detect sensorimotor neuropathies and cervical pathology
- Evaluate spinal cord and brain injury and function
- Monitor sensory potentials to determine spinal cord function during a surgical procedure or medical regimen

**ERP (potentials):**
- Detect suspected psychosis or dementia
- Differentiate between organic brain disorder and cognitive function abnormality

**RESULT:**

**Normal findings in:**

**VER and ABR:** Normal latency in recorded cortical and brainstem waveforms depending on age, gender, and stature

**ERP:** Normal recognition and attention span

**SER:** No loss of consciousness or presence of weakness
Abnormal findings in:

- **VER (potentials):**
  P100 latencies (extended) confined to one eye suggest a lesion anterior to the optic chiasm.
  Bilateral abnormal P100 latencies indicate multiple sclerosis, optic neuritis, retinopathies, spinocerebellar degeneration, sarcoidosis, Parkinson’s disease, adrenoleukodystrophy, Huntington’s chorea, or amblyopias.

- **ABR (potentials):**
  Normal response at high intensities; wave V may occur slightly later. Earlier wave distortions suggest cochlear lesion.
  Absent or late waves at high intensities; increased amplitude of wave V suggests retrocochlear lesion.

- **SER (potentials):**
  Abnormal upper limb latencies suggest cervical spondylosis or intracerebral lesions.
  Abnormal lower limb latencies suggest peripheral nerve root disease such as Guillain-Barré syndrome, multiple sclerosis, transverse myelitis, or traumatic spinal cord injuries.

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

- Factors that may impair the results of the examination:
  - Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status *(Note: significant behavioral problems may limit the ability to complete the test).*
  - Improper placement of electrodes
  - Patient stress, which can affect brain chemistry, thus making it difficult to distinguish whether the results are due to the patient’s emotional reaction or to organic pathology
  - Extremely poor visual acuity, which can hinder accurate determination of VER
  - Severe hearing loss, which can interfere with accurate determination of ABR

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient this procedure measures electrical activity in the nervous system.
- Obtain a history of the patient’s complaints or symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast mediums.
- Obtain a history of the patient’s neuromuscular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that the procedure is painless and harmless. Inform the patient that the procedure is performed in a special laboratory by a health care provider (HCP) and takes approximately 30 min to 2 hr, depending on the type of studies required.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to clean the hair and to refrain from using hair sprays, creams, or solutions before the test.
Somatosensory Evoked Potentials:
Place the patient in a comfortable position, and place the electrodes at the nerve sites of the wrist, knee, and ankle and on the scalp at the sensory cortex of the hemisphere on the opposite side (the electrode that picks up the response and delivers it to the recorder). Additional electrodes can be positioned at the cervical or lumbar vertebrae for upper or lower limb stimulation. The rate at which the electric shock stimulus is delivered to the nerve electrodes and travels to the brain is measured, computer analyzed, and recorded in waveforms for analysis. Both sides of the area being examined can be tested by switching the electrodes and repeating the procedure.

Event-Related Potentials:
Place the patient in a sitting position in a chair in a quiet room. Earphones are placed on the patient’s ears and auditory cues administered. The patient is asked to push a button when the tones are recognized. Flashes of light are also used as visual cues, with the client pushing a button when cues are noted. Results are compared to normal EP waveforms for correct, incorrect, or absent responses.

POST-TEST:
A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
When the procedure is complete, remove the electrodes and clean the skin where the electrodes were applied.
Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or
Exercise Stress Test

**SYNONYM/ACRONYM:** Exercise electrocardiogram (ECG, EKG), graded exercise tolerance test, stress testing, treadmill test.

**AREA OF APPLICATION:** Heart.

**CONTRAST:** None.

**DESCRIPTION:** The exercise stress test is a noninvasive study to measure cardiac function during physical stress. Exercise electrocardiography is primarily useful in determining the extent of coronary artery occlusion by the heart’s ability to meet the need for additional oxygen in response to the stress of exercising in a safe environment. The patient exercises on a treadmill or pedals a stationary bicycle to increase the heart rate to 80% to 90% of maximal heart rate determined by age and gender, known as the target heart rate. Every 2 to 3 min the speed and/or grade of the treadmill is increased to yield an increment of stress. The patient’s electrocardiogram (ECG) and blood pressure are monitored during the test. The test proceeds until the patient reaches the target heart rate or experiences chest pain or fatigue. The risks involved in the procedure are possible myocardial infarction (1 in 500) and death (1 in 10,000) in patients experiencing frequent angina episodes before the test. Although useful, this procedure is not as accurate as cardiac nuclear scans for diagnosing coronary artery disease (CAD).

For patients unable to complete the test, pharmacological stress testing can be done. Medications used to pharmacologically exercise the patient’s heart include vasodilators such as...
as dipyridamole and adenosine or dobutamine (which stimulates heart rate and pumping force). The patient’s electrocardiogram (ECG) and blood pressure are monitored during the test. The test proceeds until the stimulated exercise portion when a radiotracer, such as technetium-99m or sestamibi, is injected. Pictures are taken by a gamma camera during the stimulated portion and compared with images taken at rest.

**INDICATIONS:**
- Detect dysrhythmias during exercising, as evidenced by ECG changes
- Detect peripheral arterial occlusive disease (intermittent claudication), as evidenced by leg pain or cramping during exercising
- Determine exercise-induced hypertension
- Evaluate cardiac function after myocardial infarction or cardiac surgery to determine safe exercise levels for cardiac rehabilitation as well as work limitations
- Evaluate effectiveness of medication regimens, such as antianginals or antiarrhythmics
- Evaluate suspected CAD in the presence of chest pain and other symptoms
- Screen for CAD in the absence of pain and other symptoms in patients at risk

**RESULT:**

**Normal findings in:**
- Normal heart rate during physical exercise. Heart rate and systolic blood pressure rise in direct proportion to workload and to metabolic oxygen demand, which is based on age and exercise protocol. Maximal heart rate for adults is normally 150 to 200 beats/min.

**Abnormal findings in:**
- Activity intolerance related to oxygen supply and demand imbalance
- Bradycardia
- CAD
- Chest pain related to ischemia or inflammation
- Decreased cardiac output
- Dysrhythmias
- Hypertension
- Peripheral arterial occlusive disease
- S-T segment depression of 1 mm (considered a positive test), indicating myocardial ischemia
- Tachycardia

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
The following factors may impair interpretation of examination results because they create an artificial state that makes it difficult to determine true physiological function:
- Anxiety or panic attack
- Drugs such as β-blockers, cardiac glycosides, calcium channel blockers, coronary vasodilators, and barbiturates
- High food intake or smoking before testing
- Hypertension, hypoxia, left bundle branch block, and ventricular hypertrophy
- Improper electrode placement
- Potassium or calcium imbalance
- Viagra should not be taken in combination with nitroglycerin or other nitrates 24 hr prior to the procedure as it may result in a dangerously low blood pressure
- Wolff-Parkinson-White syndrome (anomalous atrioventricular excitation)
INTRATEST:

- Ensure the patient has complied with dietary and tobacco restrictions for at least 4 hr prior to the procedure.
- An IV access may be established for emergency use.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown provided.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place electrodes in appropriate positions on the patient and connect a blood pressure cuff to a monitoring device. If the patient’s oxygen consumption is to be continuously monitored, connect the patient to a machine via a mouthpiece or to a pulse oximeter via a finger lead.
- Instruct the patient to walk on a treadmill (most commonly used) and use the handrails to maintain balance or to peddle a bicycle. As stress is increased, inform the patient to report symptoms, such as chest or leg pain, dyspnea, or fatigue.
- Turn the treadmill on at a slow speed, and increase in speed and elevation to raise the patient’s heart rate. Increase the stress until the patient’s predicted target heart rate is reached.
- Instruct the patient to report symptoms such as dizziness, sweating, breathlessness, or nausea, which can be normal, as speed increases. The test is terminated if pain or fatigue is severe; maximum heart rate under stress is attained; signs of ischemia are present; maximum effort has been achieved; or dyspnea, hypertension (systolic blood pressure greater than 200 mm Hg, diastolic blood pressure greater than 110 mm Hg, or both), tachycardia (greater than 200 beats/min minus person’s age), new dysrhythmias, chest pain that begins or worsens, faintness, extreme dizziness, or confusion develops.
- After the exercise period, allow a 3- to 15-min rest period with the patient in a sitting position. During this period, the ECG, blood pressure, and heart rate monitoring is continued.

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test assesses the heart’s ability to respond to an increasing workload.
- Obtain a history of the patient’s cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Inquire if the patient has had any chest pain within the past 48 hr, or has a history of anginal attacks; if either of these have occurred, inform the health care provider (HCP) immediately because the stress test may be too risky and should be rescheduled in 4 to 6 wk.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some discomfort may be experienced during the stimulated portion of the test. Inform the patient that the procedure is performed in a special department by a HCP specializing in this procedure and takes approximately 30 to 60 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Record a baseline 12-lead ECG and vital signs.
- Instruct the patient to wear comfortable shoes and clothing for the exercise.
- Instruct the patient to fast, restrict fluids, and avoid tobacco products for 4 hr prior to the procedure. Protocols may vary from facility to facility.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.
Remove the electrodes and cleanse the skin of any remaining gel or ECG electrode adhesive.

**POST-TEST:**

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual activity, as directed by the HCP.
- Instruct the patient to contact the HCP to report any anginal pain or other discomforts experienced after the test.
- Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, atrial natriuretic peptide, BNP, blood gases, blood pool imaging, calcium, chest x-ray, cholesterol (total, HDL, LDL), CT cardiac scoring, CT thorax, CRP, CK and isoenzymes, echocardiography, echocardiography transesophageal, electrocardiogram, glucose, glycoated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isos, lipoprotein electrophoresis, lung perfusion scan, magnesium, MRI chest, MI infarct scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, pulse oximetry, sodium, triglycerides, and troponin.
- Refer to the Cardiovascular System table at the back of the book for related tests by body system.

**FDG-PET Scan**

**SYNONYM/ACRONYM:** Fluorodeoxyglucose (FDG)-positron emission tomography (PET).

**AREA OF APPLICATION:** Abdomen, brain, breast, heart, pelvis

**CONTRAST:** IV radioactive material fluorodeoxyglucose (FDG).

**DESCRIPTION:** Fluorine-18, in the form of fluorodeoxyglucose (FDG), is one of the more commonly used radionuclides. FDG is a glucose analogue, and because every cell uses glucose, the metabolic activity occurring in neurological conditions can be measured. There is little localization of FDG in normal tissue, allowing rapid detection of abnormal disease states. The brain uses oxygen and glucose almost exclusively to meet its energy needs, and therefore the brain's metabolism has been studied widely with positron emission tomography (PET). The role of this procedure is to detect metabolically active malignant lesions. FDG-PET scan may also be used to stage and monitor the response to the malignant disease.

PET combines the biochemical properties of nuclear medicine with the accuracy of computed tomography (CT). PET uses positron emissions from specific radionuclides (oxygen, nitrogen, carbon, and fluorine) to produce detailed functional images within the body. The positron radiopharmaceuticals generally have short half-lives, ranging from a few seconds to a few hours, and therefore they must be produced in a cyclotron located near where the test is being done. The PET scanner translates the emissions from the radioactivity as the positron combines with the negative electrons from the tissues and forms gamma rays that can be detected by the scanner. This information is transmitted to the computer, which determines the location and its distribution and translates the emissions as color-coded images for viewing, quantitative measurements, activity changes in relation to time, and three-dimensional computer-aided analysis.

The expense of the study and the limited availability of radiopharmaceuticals limit the use of PET, even though it is more sensitive than traditional nuclear scanning and single-photon emission computed tomography. Changes in reimbursement and the advent of mobile technology have increased the availability of this procedure in the community setting.

**INDICATIONS:**
- Detect Parkinson’s disease and Huntington’s disease, as evidenced by decreased metabolism
- Determine physiological changes in psychosis and schizophrenia
- Evaluate Alzheimer’s disease and differentiate it from other causes of dementia, as evidenced by decreased cerebral flow and metabolism
- Evaluate coronary artery disease (CAD), as evidenced by decreased myocardial blood flow and myocardial perfusion
• Evaluate myocardial viability, as evidenced by low glucose metabolism
• Evaluate tumors preoperatively and postoperatively and determine grade, stage, and appropriate treatment or procedure
• Identify cerebrovascular accident or aneurysm, as evidenced by decreased blood flow and oxygen use
• Identify focal seizures, as evidenced by decreased metabolism between seizures

RESULT:

Normal findings in:
• Normal patterns of tissue metabolism, blood flow, and radionuclide distribution

Abnormal findings in:
• Alzheimer’s disease
• Brain trauma
• Breast cancer
• Colorectal cancer
• CAD
• Epilepsy
• Heart muscle dysfunction
• Huntington’s disease
• Infections
• Lung cancer
• Lymphoma
• Melanoma
• Metastatic disease
• Myeloma
• Ovarian cancer
• Pancreatic cancer
• Parkinson’s disease

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Drugs that alter glucose metabolism, such as tranquilizers, sedatives, or insulin, because hypoglycemia can alter PET results
• The use of alcohol, tobacco, or caffeine-containing drinks at least 24 hr before the study, because the effects of these substances, make it difficult to evaluate the patient’s true physiological state (e.g., alcohol is a vasoconstrictor and would decrease blood flow to the target organ)
• Excessive exercise in the preceding 3 days, which can cause factitious uptake of the contrast material in the musculature
• Excessive anxiety may affect valuation of brain function
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

Other considerations:
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure helps assess blood flow to and tissue metabolism in the abdomen, brain, breast, heart, and pelvis.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
- Obtain a history of results of the patient’s cardiovascular, hematopoietic, musculoskeletal, or reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- Record the date of last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department, by a HCP specializing in this procedure, with support staff, and takes approximately 1 to 3 hr.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct patients with diabetes to take their pretest dose of insulin at a meal 4 hr before the test.
- Sometimes FDG examinations are done after blood has been drawn to determine circulating blood glucose levels. If blood glucose levels are high, insulin may be given.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to restrict food for 4 to 6 hr; restrict alcohol, nicotine, or caffeine-containing drinks for 24 hr; and withhold medications for 24 hr before the test. The exception is that there are no dietary restrictions for patients undergoing cardiac imaging. Protocols may vary from facility and facility.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

- Ensure that the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations prior to the procedure.
- Ensure that the patient has removed external metallic objects from the area to be examined prior to the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Record baseline vital signs and assess neurological status. Protocols may vary from facility to facility.
- Cardiac imaging patients may be asked to drink glucose prior to the radionuclide injection.
- Place the patient in the supine position on an exam table.
- The radionuclide is injected, and imaging is started after a 30-min delay. Images may be recorded for up to 3 hr postinjection.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
FDG-PET SCAN

POST-TEST:

- Remove the needle or catheter and apply a pressure dressing over the puncture site.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

- Nutritional considerations: A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and CAD.

- No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

- Related tests include AFP, Alzheimer’s disease markers, amino acid screen, amylase, barium enema, biopsy breast, biopsy lung, bronchoscopy, calcitonin, CEA and cancer antigens, complete blood count, WBC count and differential, CSF analysis, colonoscopy, CT abdomen, CT brain, CT pancreas, CT pelvis, cytology sputum, evoked brain potentials, exercise stress test, fecal analysis, gallium scan, laparoscopy abdominal, laparoscopy gyn, lymphangiogram, mammography, MRI abdomen, MRI brain, MRI breast, MRI pelvis, myocardial perfusion heart scan, peritoneal fluid analysis, PET brain, PET heart, PET pelvis, proctosigmoidoscopy, stereotactic breast biopsy, US breast, US pancreas, US pelvis gyn, and WBC scan.
- Refer to the Cardiovascular, Hematopoietic, Musculoskeletal, or Reproductive System tables at the back of the book for related tests by body system.

Access additional resources at davisplus.fadavis.com
**Fecal Analysis**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Stool.

**REFERENCE VALUE:** (Method: Macroscopic examination, for appearance and color; microscopic examination, for cell count and presence of meat fibers; leukocyte esterase, for leukocytes; Clinitest [Bayer Corporation, Pittsburgh, Pennsylvania] for reducing substances; guaiac, for occult blood; x-ray paper, for trypsin).

### Characteristic | Normal Result
--- | ---
Appearance | Solid and formed
Color | Brown
Epithelial cells | Few to moderate
Fecal fat | See “Fecal Fat” monograph
Leukocytes (white blood cells) | Negative
Meat fibers | Negative
Occult blood | Negative
Reducing substances | Negative
Trypsin | 2+ to 4+

**DESCRIPTION:** Feces consist mainly of cellulose and other undigested foodstuffs, bacteria, and water. Other substances normally found in feces include epithelial cells shed from the gastrointestinal (GI) tract, small amounts of fats, bile pigments in the form of urobilinogen, GI and pancreatic secretions, electrolytes, and trypsin. Trypsin is a proteolytic enzyme produced in the pancreas. The average adult excretes 100 to 300 g of fecal material per day, the residue of approximately 10 L of liquid material that enters the GI tract each day. The laboratory analysis of feces includes macroscopic examination (volume, odor, shape, color, consistency, presence of mucus), microscopic examination (leukocytes, epithelial cells, meat fibers), and chemical tests for specific substances (occult blood, trypsin, estimation of carbohydrate). Detection of occult blood is the most common test performed on stool. The prevalence of colorectal adenoma is greater than 30% in people aged 60 and older. Progression from adenoma to carcinoma occurs over a period of 5 to 12 yr; from carcinoma to metastatic disease in 2 to 3 yr. The American Cancer Society recommends one of several screening protocols beginning at age 50 to include: annual fecal occult blood, flexible sigmoidoscopy every 5 yr, double contrast barium enema every 5 yr, colonoscopy every 10 yr.
**INDICATIONS:**
- Assist in diagnosing disorders associated with GI bleeding or drug therapy that leads to bleeding
- Assist in the diagnosis of pseudomembranous enterocolitis after use of broad-spectrum antibiotic therapy
- Assist in the diagnosis of suspected inflammatory bowel disorder
- Detect altered protein digestion
- Detect intestinal parasitic infestation, as indicated by diarrhea of unknown cause
- Investigate diarrhea of unknown cause
- Monitor effectiveness of therapy for intestinal malabsorption or pancreatic insufficiency
- Screen for cystic fibrosis

**RESULT:**

**Unusual Appearance:**
- Bloody: *Excessive intestinal wall irritation or malignancy*
- Bulky or frothy: *Malabsorption*
- Mucous: *Inflammation of intestinal walls*
- Slender or ribbonlike: *Obstruction*

**Unusual Color:**
- Black: *Bismuth (antacid) or charcoal ingestion, iron therapy, upper GI bleed*
- Grayish white: *Barium ingestion, bile duct obstruction*
- Green: *Antibiotics, biliverdin, green vegetables*
- Red: *Beets and food coloring, lower GI bleed, phenazopyridine hydrochloride compounds, rifampin*
- Yellow: *Rhubarb*

**Increased:**
- Carbohydrates/reducing substances: *Malabsorption syndromes*
- Epithelial cells: *Inflammatory bowel disorders*
- Leukocytes: *Bacterial infections of the intestinal wall, salmonellosis, sbigellosis, and ulcerative colitis*
- Meat fibers: *Altered protein digestion*
- Occult blood: *Anal fissure, diverticular disease, esophageal varices, esophagitis, gastritis, hemorrhoids, infectious diarrheas, inflammatory bowel disease, Mallory-Weiss tears, polyps, tumors, ulcers*

**Decreased:**
- Leukocytes: *Amebic colitis, cholera, disorders resulting from toxins, parasites, viral diarrheas*
- Trypsin: *Cystic fibrosis, malabsorption syndromes, pancreatic deficiency*

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that can cause positive results for occult blood include acetylsalicylic acid, anticoagulants, colchicine, corticosteroids, iron preparations, and phenylbutazone.
- Ingestion of a diet high in red meat, certain vegetables, and bananas can cause false-positive results for occult blood.
- Large doses of vitamin C can cause false-negative occult blood.
- Constipated stools may not indicate any trypsin activity owing to extended exposure to intestinal bacteria.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of intestinal disorders.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
Obtain a history of the patient’s gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient of the procedure for collecting a stool sample, including the importance of good handwashing techniques. The patient should place the sample in a tightly covered container. Instruct the patient not to contaminate the specimen with urine, water, or toilet tissue. Address concerns about pain and explain that there should be no discomfort during the procedure.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient not to use laxatives, enemas, or suppositories for 3 days before the test.

Instruct the patient to follow a normal diet. If the test is being performed to identify blood instruct the patient to follow a special diet that includes small amounts of chicken, turkey, and tuna (no red meats), raw and cooked vegetables and fruits, and bran cereal for several days before the test. Foods to avoid with the special diet include beets, turnips, cauliflower, broccoli, bananas, parsnips, and cantaloupe, since these foods can interfere with the occult blood test.

INTRATEST:

Ensure that the patient has complied with medication restrictions; assure laxatives, enemas, or suppositories have been restricted for at least 3 days prior to the procedure.

Instruct the patient to cooperate fully and to follow directions.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date and time of collection, and suspected cause of enteritis; note any current or recent antibiotic therapy.

Collect a stool specimen in a half-pint waterproof container with a tight-fitting lid; if the patient is not ambulatory, collect it in a clean, dry bedpan. Use a tongue blade to transfer the specimen to the container, and include any mucoid and bloody portions. Collect specimen from the first, middle, and last portion of the stool. The specimen should be refrigerated if it will not be transported to the laboratory within 4 hr after collection.

To collect specimen by rectal swab, insert the swab past the anal sphincter, rotate gently, and withdraw. Place the swab in the appropriate container.

Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include α1-antitrypsin/phenotyping, barium enema, biopsy intestine, capsule endoscopy, CEA and cancer antigens, chloride sweat, colonoscopy, CT colonoscopy, culture stool, D-xylose tolerance, fecal fat, gliadin antibody, lactose tolerance test, ova and parasites, and proctosigmoidoscopy.

Refer to the Gastrointestinal System table at the end of the book for related tests by body system.
Fecal Fat

SYNONYM/ACRONYM: Stool fat, fecal fat stain.

SPECIMEN: Stool (80 mL) aliquot from an unpreserved and homogenized 24- to 72-hr timed collection. Random specimens may also be submitted.

REFERENCE VALUE: (Method: Stain with Sudan black or oil red O. Treatment with ethanol identifies neutral fats; treatment with acetic acid identifies fatty acids.)

<table>
<thead>

*hpf = high-power field.

DESCRIPTION: Fecal fat primarily consists of triglycerides (neutral fats), fatty acids, and fatty acid salts. Through microscopic examination, the number and size of fat droplets can be determined as well as the type of fat present. Excretion of more than 7 g of fecal fat in a 24-hr period is abnormal but nonspecific for disease. Increases in excretion of neutral fats are associated with pancreatic exocrine insufficiency, whereas decreases are related to small bowel disease. An increase in triglycerides indicates that insufficient pancreatic enzymes are available to convert the triglycerides into fatty acids. Patients with malabsorption conditions have normal amounts of triglycerides but an increase in total fecal fat because the fats are not absorbed through the intestine. Malabsorption disorders (e.g., cystic fibrosis) cause blockage of the pancreatic ducts by mucus, which prevents the enzymes from reaching the duodenum and results in lack of fat digestion. Without digestion, the fats cannot be absorbed, and steatorrhea results. The appearance and odor of stool from patients with steatorrhea is typically foamy, greasy, soft, and foul-smelling. The semiquantitative test is used to screen for the presence of fecal fat. The quantitative method, which requires a 72-hr stool collection, measures the amount of fat present in grams.

Access additional resources at davisplus.fadavis.com
INDICATIONS:
- Assist in the diagnosis of malabsorption or pancreatic insufficiency, as indicated by elevated fat levels
- Monitor the effectiveness of therapy

RESULT:

*Increased in:*
- Abetalipoprotein deficiency (*Related to lack of transport proteins for absorption*)
- Addison’s disease (*Related to impaired transport*)
- Amyloidosis (*Increased rate of excretion related to malabsorption*)
- Bile salt deficiency (*Lack of bile salts affects proper fat digestion*)
- Carcinoid syndrome (*Increased rate of excretion related to malabsorption*)
- Celiac disease (*Increased rate of excretion related to malabsorption*)
- Cystic fibrosis (*Related to insufficient digestive enzymes*)
- Diabetes (*Abnormal motility related to primary condition*)
- Enteritis (*Increased rate of excretion related to malabsorption*)
- Malnutrition (*Related to detrimental effects on organs and systems responsible for digestion, transport, and absorption*)
- Multiple sclerosis (*Abnormal motility related to primary condition*)
- Pancreatic insufficiency or obstruction (*Related to insufficient digestive enzymes*)
- Peptic ulcer disease (*Related to improper digestion due to low pH*)
- Pernicious anemia (*Related to bacterial overgrowth that decreases overall absorption and results in vitamin B₁₂ deficiency*)
- Progressive systemic sclerosis (*Abnormal motility related to primary condition*)
- Thyrotoxicosis (*Abnormal motility related to primary condition*)
- Tropical sprue (*Increased rate of excretion related to malabsorption*)
- Viral hepatitis (*Related to insufficient production of digestive enzymes and bile*)
- Whipple’s disease (*Increased rate of excretion related to malabsorption*)
- Zollinger-Ellison syndrome (*Related to improper digestion due to low pH*)

*Decreased in:* N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Cimetidine has been associated with decreased fecal fat in some patients with cystic fibrosis who are also receiving pancreatic enzyme therapy.
- Some drugs cause steatorrhea as a result of mucosal damage. These include colchicine, kanamycin, lincomycin, methotrexate, and neomycin. Other drugs that can cause an increase in fecal fat include aminosalicylic acid, bisacodyl and phenolphthalein (observed in laxative abusers), and cholestyramine (in high doses).
- Use of suppositories, oily lubricants, or mineral oil in the perianal area for 3 days before the test can falsely increase neutral fats.
- Use of herbals with laxative effects, including cascara, psyllium, and senna, for 3 days before the test can falsely increase neutral fats.
• Barium interferes with test results.
• Failure to collect all stools may reflect falsely decreased results.
• Ingestion of a diet too high or low in fats may alter the results.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of malabsorption syndromes.
- Obtain a history of the patient’s complaints that indicate a gastrointestinal (GI) disorder, diarrhea related to GI dysfunction, pain related to tissue inflammation or irritation, alteration in diet resulting from an inability to digest certain foods, or fluid volume deficit related to active loss. Obtain a history of known allergens.
- Obtain a history of the patient’s GI and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Stress the importance of collecting all stools for the quantitative test, including diarrhea, over the timed specimen-collection period. Inform the patient not to urinate in the stool-collection container and not to put toilet paper in the container. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during and after the procedure.
- Instruct the patient not to use laxatives, enemas, or suppositories for 3 days before the test.
- There are no fluid restrictions, unless by medical direction.

**INTRATEST:**
- Ensure that the patient has complied with dietary and other pretesting preparations prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and the start and stop times of collection.
- Obtain the appropriate-sized specimen container, toilet-mounted collection container to aid in specimen collection, and plastic bag for specimen transport. A large, clean, preweighed container should be used for the timed test. A smaller, clean container can be used for the collection of the random sample.
- For the quantitative procedure, instruct the patient to collect each stool and place it in the 500-mL container during the timed collection period. Keep the container refrigerated in the plastic bag throughout the entire collection period. Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume usual diet and medication, as directed by the HCP.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Instruct the patient with abnormal values on the importance of fluid intake and proper diet specific to his or her condition. Provide teaching and information regarding the clinical
implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include α₁-antitrypsin/phenotyping, biopsy intestine, chloride sweat, complete blood count, complete blood count, RBC indices, complete blood count, RBC morphology, D-xylose tolerance test, fecal analysis, folate, gastric acid stimulation test, gastric emptying scan, radioactive iodine uptake, and vitamin B₁₂.
- Refer to the Gastrointestinal and Respiratory System tables at the back of the book for related tests by body system.

**DESCRIPTION:** Ferritin, a protein manufactured in the liver, spleen, and bone marrow, consists of a protein shell, apoferritin, and an iron core. The amount of ferritin in the circulation is usually proportional to the amount of stored iron (ferritin and hemosiderin) in body tissues. Levels vary according to age and gender, but they are not affected by exogenous iron intake or subject to diurnal variations. Compared to iron and total iron-binding capacity, ferritin is a more sensitive and specific test for diagnosing
**INDICATIONS:**
- Assist in the diagnosis of iron-deficiency anemia
- Assist in the differential diagnosis of microcytic, hypochromic anemias
- Monitor hematological responses during pregnancy, when serum iron is usually decreased and ferritin may be decreased
- Support diagnosis of hemochromatosis or other disorders of iron metabolism and storage

**RESULT:**

**Increased in:**
- Alcoholism *(Active abuse, ferritin is released into the circulation from damaged hepatocytes and RBCs)*
- Breast cancer *(Acute, ferritin is an acute phase reactant protein; chronic, pathophysiology is uncertain)*
- Hemochromatosis *(Increased iron deposits in the liver stimulate ferritin production)*
- Hemolytic anemia *(Increased iron levels from hemolyzed RBCs stimulate ferritin production)*
- Hemosiderosis *(Increased iron levels stimulate ferritin production)*
- Hepatocellular disease *(Acute, ferritin is an acute phase reactant protein; chronic, ferritin is released into the circulation from damaged hepatocytes)*
- Hodgkin’s disease *(Acute, ferritin is an acute phase reactant protein; chronic, pathophysiology is uncertain)*
- Hyperthyroidism *(Possibly related to the stimulating effect of TSH on ferritin production)*
- Infection *(Acute, ferritin is an acute phase reactant protein; chronic, pathophysiology is uncertain)*
- Inflammatory diseases *(Ferritin is an acute phase reactant protein)*
- Leukemias *(Acute, ferritin is an acute phase reactant protein; chronic, pathophysiology is uncertain)*
- Oral or parenteral administration of iron *(An increased circulating iron level stimulates ferritin production)*
- Thalassemia *(Increased iron levels from hemolyzed RBCs stimulate ferritin production)*

**Decreased in:**
Conditions that decrease iron stores result in corresponding low levels of ferritin.
- Hemodialysis
- Iron-deficiency anemia

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase ferritin levels include ethanol, ferric polymaltose, iron, and oral contraceptives.
- Drugs that may decrease ferritin levels include erythropoietin, methimazole, propylthiouracil, and thiamazole.
- Recent transfusion can elevate serum ferritin.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of hypochromic, microcytic anemias.

Access additional resources at davisplus.fadavis.com
Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient’s hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Note any recent procedures that can interfere with test results.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

*Sensitivity to social and cultural issues,* as well as concern for modesty is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

**Nutritional considerations:** Nutritional therapy may be indicated for patients with decreased ferritin values because this may indicate corresponding iron deficiency. Instruct these patients in the dietary inclusion of iron-rich foods and in the administration of iron supplements, including side effects, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include biopsy bone marrow, biopsy liver, complement, complete blood count, complete blood count, hematocrit, complete blood count, hemoglobin, complete blood count, platelet count, complete blood count, RBC count, complete blood count, RBC indices, complete blood count, RBC morphology and inclusions, complete blood count, WBC count and differential, Coomb’s antiglobulin direct and indirect, erythropoietin, FEP, G6PD, Ham’s test, Hgb electrophoresis, hemosiderin, iron/TIBC, osmotic fragility, PK, sickle cell screen, and transferrin.

Refer to the Hematopoietic System table at the back of the book for related tests by body system.
Fetal Fibronectin

SYNONYM/ACRONYM: ffN.

SPECIMEN: Swab of vaginal secretions

REFERENCE VALUE: (Method: Immunoassay) Less than 0.05 mcg/mL.

DESCRIPTION: Fibronectin is a protein found in fetal connective tissue, amniotic fluid, and the placenta of pregnant women. Placental ffN is concentrated in the area where the placenta and its membranes are in contact with the uterine wall. It is first secreted early in pregnancy and is believed to help implantation of the fertilized egg to the uterus. Fibronectin is not detectable again until 22 to 34 wk of gestation; if it is detected in vaginal secretions at this gestational age, delivery may happen prematurely. The test is a useful marker for impending membrane rupture within 7 to 14 days if the level rises to greater than 0.05 mcg/mL.

INDICATIONS:
Investigate signs of premature labor

RESULT:
Positive findings in:
• Premature labor (Possibly initiated by mechanical or infectious processes, the membranes pull away from the uterine wall and amniotic fluid containing ffN leaks into endocervical fluid)

Negative findings in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
If signs and symptoms persist in light of negative test results, repeat testing may be necessary.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to assess the risk of preterm delivery.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Ensure that the patient knows the symptoms of premature labor, which include uterine contractions (with or without pain) lasting 20 sec or longer or increasing in frequency, menstrual-like cramping (intermittent or continuous), pelvic pressure, lower back pain that does not dissipate with a change in position, persistent diarrhea, intestinal cramps, changes in vaginal discharge, or a feeling that something is wrong.
• The health care provider (HCP) should be informed if contractions occur more frequently than 4 times per hr.
• Obtain a list of the patient’s current medications, including herbs,
nutritional supplements, and nutraceuticals.

- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min and will be performed by a HCP specializing in this branch of medicine. Address concerns about pain related to the procedure. Explain to the patient that there should be minimal to no discomfort during the procedure.

- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

- Position the patient on the gynecological examination table with the feet up in stirrups. Drape the patient’s legs to provide privacy and to reduce chilling. Collect a small amount of vaginal secretion using a special swab from a fetal fibronectin kit.

- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Explain the possible causes and increased risks associated with premature labor and delivery. Reinforce education on signs and symptoms of labor, as appropriate. Inform the patient that hospitalization or more frequent prenatal checks may be ordered. Other therapies may also be administered, such as antibiotics, corticosteroids, and IV tocolytics. Instruct the patient in the importance of completing the entire course of antibiotic therapy, if ordered, even if no symptoms are present. Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include amniotic fluid analysis (nitrazine and fern test), biopsy chorionic villus, chromosome analysis, estradiol, α-fetoprotein, HCG, LS ratio, progesterone, and US biophysical profile obstetric.

- Refer to the Reproductive System table at the end of the book for related tests by body system.
**SYNONYM/ACRONYM:** AFP.

**SPECIMEN:** Serum (1 mL for tumor marker in men and nonpregnant women; 3 mL for maternal triple- or quad-marker testing), collected in a red- or tiger-top tube. For maternal triple- or quad-marker testing, include human chorionic gonadotropin and free estriol measurement.

**REFERENCE VALUE:** (Method: Immunoassay for tumor marker, radioimmunoassay for maternal triple- or quad-marker testing)

**Tumor Marker: Men, Women, and Children.**

Results vary widely from laboratory to laboratory and method to method. HCG = human chorionic gonadotropin.
DESCRIPTION: α₁-Fetoprotein (AFP) is a glycoprotein produced in the fetal liver, gastrointestinal tract, and yolk sac. AFP is the major serum protein produced for 10 wk in early fetal life. (See “Amniotic Fluid Analysis” monograph for measurement of AFP levels in amniotic fluid.) After 10 wk of gestation, levels of fetal AFP can be detected in maternal blood, with peak levels occurring at 16 to 18 wk. Elevated maternal levels of AFP on two tests taken 1 wk apart suggest further investigation into fetal well-being by ultrasound or amniocentesis. Human chorionic gonadotropin (HCG), a hormone secreted by the placenta, stimulates secretion of progesterone by the corpus luteum. (The use of HCG as a triple marker is also discussed in the monograph titled “Human Chorionic Gonadotropin.”) During intrauterine development, the normal fetus and placenta produce estriol, a portion of which passes into maternal circulation. Decreased estriol levels are an independent indicator of neural tube defects. The incidence of neural tube defects is about 1 in 1000 births. Dimeric inhibin-A (DIA) is the fourth biochemical marker used in prenatal screening. It is a glycoprotein secreted by the placenta. Maternal blood levels of DIA normally remain fairly stable during the 15th to 18th wk of pregnancy. Blood levels are twice as high in the second trimester of pregnancies affected by Down syndrome. The triple screen detection rate for Down syndrome is 67%. The Down syndrome detection rate increases to 76% and maintains a false-positive rate of 5% when DIA is included.

INDICATIONS:
- Assist in the diagnosis of primary hepatocellular carcinoma or metastatic lesions involving the liver, as indicated by highly elevated levels (30% to 50% of Americans with liver cancer do not have elevated AFP levels)
- Investigate suspected hepatitis or cirrhosis, indicated by slightly to moderately elevated levels
- Monitor response to treatment for hepatic carcinoma, with successful treatment indicated by an immediate decrease in levels
- Monitor for recurrence of hepatic carcinoma, with elevated levels occurring 1 to 6 mo before the patient becomes symptomatic
- Investigate suspected intrauterine fetal death, as indicated by elevated levels
- Routine prenatal screening at 13 to 16 wk of pregnancy for fetal neural tube defects and other disorders, as indicated by elevated levels in maternal serum and amniotic fluid
- Support diagnosis of embryonal gonadal teratoblastoma, hepatoblastoma, and testicular or ovarian carcinomas

RESULT:
Maternal serum AFP test results report actual values and multiples of the median (MoM) by gestational age (in weeks). MoM are calculated by dividing the patient’s AFP by the midpoint (or median) of values expected for a large population of unaffected women at the same gestational age in weeks. MoM should be corrected for

The presence of AFP in excessive amounts is abnormal in adults and children. AFP measurements are used as a tumor marker to assist in the diagnosis of cancer.
maternal weight. The MoM should also be corrected for maternal insulin requirement (achieved by dividing MoM by 1.1 for diabetic African American patients and by 0.8 for diabetic patients of other races) and multiple fetuses (multiply by 2.13 for twins). Some laboratories also provide additional statistical information regarding Down syndrome risk.

**Increased in:**
- Pregnant women:
  - Congenital nephrosis (Related to defective renal reabsorption)
  - Fetal abdominal wall defects (Related to release of AFP from open body wall defect)
  - Fetal distress
  - Fetal neural tube defects (e.g., anencephaly, spina bifida, myelomeningocele) (Related to release of AFP from open body wall defect)
  - Low birth weight (Related to inaccurate estimation of gestational age)
  - Multiple pregnancy (Related to larger quantities from multiple fetuses)
  - Polycystic kidneys (Related to defective renal reabsorption)
- Underestimation of gestational age (Related to the expectation of a lower value based on incorrect prediction of gestational age, i.e., AFP increases with age; therefore, if the age is believed to less than it is actually, the expectation of the corresponding AFP value will be lower than it is actually, and the result appears to be elevated)

- Men, nonpregnant women, and children: (The cancer cells contain undifferentiated hepatocytes that produce glycoproteins of fetal origin)
  - Cirrhosis
  - Hepatic carcinoma
  - Hepatitis
  - Metastatic lesions involving the liver

**Decreased in:**
- Pregnant women:
  - Down syndrome (trisomy 21)
  - Edwards’ syndrome (trisomy 18)
- Fetal demise (undetected over a lengthy period of time) (Related to cessation of AFP production)
- Hydatidiform moles (Partial mole may secrete some AFP)
- Overestimation of gestational age (Related to the expectation of a higher value based on incorrect prediction of gestational age, i.e., AFP increases with age; therefore, if the age is believed to greater than it is actually, the expectation of the corresponding AFP value will be is greater than it actually, and the result appears to be decreased)
- Pseudopregnancy (There is no fetus to produce AFP)
- Spontaneous abortion (There is no fetus to produce AFP)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may decrease AFP levels in pregnant women include acetaminophen, acetylsalicylic acid, and phenacetin.
- Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when radioimmunoassay is the test method.
- Multiple fetuses can cause increased levels.
- Gestational age must be between 15 and 22 wk for initial and follow-up testing. The most common cause of an abnormal MoM is inaccurate estimation of gestational age (defined as weeks from the first day of the last menstrual period).
- Maternal AFP levels vary by race.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

Access additional resources at davisplus.fadavis.com
Inform the patient that the test is primarily used to screen for neural tube defects.

Obtain a history of the patient’s complaints and known or suspected malignancy. Obtain a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient’s immune and reproductive systems, gestational age, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Note any recent procedures that can interfere with test results.

Provide required information to laboratory for triple-marker testing, including maternal birth date, weight, age, race, calculated gestational age, gestational age by ultrasound, gestational date by physical examination, first day of last menstrual period, estimated date of delivery, and whether the patient has insulin-dependent (type 1) diabetes.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

There are no food, fluid, or medication restrictions, unless by medical direction.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

The sample may be collected directly from the cord using a syringe and transferred to a red-top tube.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

**Nutritional considerations:** Hyperhomocysteinemia resulting from folate deficiency in pregnant women is believed to increase the risk of neural tube defects. Elevated levels of homocysteine are thought to chemically damage the exposed neural tissue of the developing fetus. As appropriate, instruct pregnant women to eat foods rich in folate, such as liver, salmon, eggs, asparagus, green leafy vegetables, broccoli, sweet potatoes, beans, and whole wheat.

**Social and cultural considerations:** In pregnant patients, recognize anxiety related to test results, and encourage the family to seek counseling if concerned with pregnancy termination or to seek genetic counseling if a chromosomal abnormality is determined. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Decisions regarding elective abortion should take place in the presence of both parents. Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks and difficulties of delivering and raising a developmentally challenged infant, as well as exploring other options (termination of pregnancy or adoption). It is also important to discuss feelings the mother and father may experience (e.g., guilt, depression, anger) if fetal abnormalities are detected. Educate the patient regarding access to counseling services.
In patients with carcinoma, recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Inform the pregnant patient that an ultrasound may be performed and AFP levels in amniotic fluid may be analyzed if maternal blood levels are elevated in two samples obtained 1 wk apart. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include amniotic fluid analysis, biopsy chorionic villus, CEA and cancer antigens, estradiol, fetal fibronectin, folic acid, hexosamidase, homocysteine, HCG, L/S ratio, and US biophysical profile obstetric.
- Refer to the Immune and Reproductive System tables at the end of the book for related tests by body system.

### Fibrin Degradation Products

**SYNONYM/ACRONYM:** Fibrin split products, fibrin breakdown products, FDP, FSP, FBP.

**SPECIMEN:** Plasma (1 mL) collected in special blue-top tube containing thrombin and a protease inhibitor.

**REFERENCE VALUE:** (Method: Latex agglutination)

<table>
<thead>
<tr>
<th>Conventional Units</th>
<th>SI Units (Conventional Units × 1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 5 mcg/mL</td>
<td>Less than 5 mg/dL</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** This coagulation test evaluates fibrin split products or fibrin/fibrinogen degradation products that interfere with normal coagulation and formation of the hemostatic platelet plug. After a fibrin clot has formed, the fibrinolytic system prevents excessive clotting. In the fibrinolytic system, plasmin digests fibrin. Fibrinogen also can be degraded if there is a disproportion among plasmin, fibrin, and fibrinogen. Seven substances labeled A, B, C, D, E, X, and Y result from this degradation, which can indicate abnormal coagulation. Under normal conditions, the liver and reticuloendothelial system remove fibrin split products from the circulation.
**INDICATIONS:**
- Assist in the diagnosis of suspected disseminated intravascular coagulation (DIC)
- Evaluate response to therapy with fibrinolytic drugs
- Monitor the effects on hemostasis of trauma, extensive surgery, obstetric complications, and disorders such as liver or renal disease

**RESULT:**

*Increased in:*
- DIC (*FDP can be positive in a number of conditions where the coagulation system has been excessively stimulated as a result of tissue injury and fibrin and/or fibrinogen is being degraded by plasmin)*
- Excessive bleeding (*Clot formation related to depletion of platelets and clotting factors will stimulate fibrinolysis and increase circulation of fibrin breakdown products*)
- Liver disease (*Related to decreased hepatic clearance*)
- Myocardial infarction (*FDP can be positive in a number of conditions where the coagulation system has been excessively stimulated as a result of tissue injury and fibrin and/or fibrinogen is being degraded by plasmin*)
- Obstetric complications, such as pre-eclampsia, abruptio placenta, intrauterine fetal death (*Excessive stimulation of the coagulation system, microthrombi are formed and plasminogen is released to dissolve the fibrin clots*)
- Post–cardiothoracic surgery period (*FDP can be positive in a number of conditions where the coagulation system has been excessively stimulated as a result of tissue injury and fibrin and/or fibrinogen is being degraded by plasmin*)
- Pulmonary embolism (*FDP can be positive in a number of conditions where the coagulation system has been excessively stimulated as a result of tissue injury and fibrin and/or fibrinogen is being degraded by plasmin*)
- Renal disease (*FDP can be positive in a number of conditions where the coagulation system has been excessively stimulated as a result of tissue injury and fibrin and/or fibrinogen is being degraded by plasmin*)
- Renal transplant rejection

**CRITICAL VALUES:**

*Greater than 40 mcg/mL*

Note and immediately report to the health care provider (HCP) any critically increased values and related symptoms.

**INTERFERING FACTORS:**
- Traumatic venipunctures and excessive agitation of the sample can alter test results.
- Drugs that may increase fibrin degradation product levels include heparin and fibrinolytic drugs such as streptokinase and urokinase.
- The presence of rheumatoid factor may falsely elevate results with some test kits.
- The test should not be ordered on patients receiving heparin therapy.

---

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate conditions associated with abnormal fibrinolytic and fibrinogenolytic activity, such as DIC, deep vein thrombosis, and pulmonary embolism.
Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient’s cardiovascular and hematopoietic systems, any bleeding disorders, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Note any recent procedures that can interfere with test results.

Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and uterine prolapses (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to report bleeding from skin or mucous membranes, ecchymosis, petechiae, hematuria and occult blood.

Inform the patient with increased levels of fibrin degradation products of the importance of taking precautions against bruising and bleeding, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of acetylsalicylic acid and similar products, and avoidance of intramuscular injections.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include aPTT, ALT, alveolar/arterial gradient, angiography pulmonary, AT-III, AST, bilirubin, biopsy liver, blood pool imaging, BUN, coagulation factors, CT cardiac scoring, creatinine, complete blood count, CK and isoenzymes, CRP, D-dimer, exercise stress test, FDP, fibrinogen, GGT, lung perfusion scan, lung ventilation scan, myoglobin, plasminogen, platelet count, PET heart, protein S, PT/INR, troponin, US venous doppler extremity studies, and venography lower extremity studies.

Refer to the Cardiovascular and Hematopoietic System tables at the end of the book for related tests by body system.
**Fibrinogen**

**SYNONYM/ACRONYM:** Factor I.

**SPECIMEN:** Plasma (1 mL) collected in blue-top (sodium citrate) tube.

**REFERENCE VALUE:** (Method: Photo-optical clot detection)

<table>
<thead>
<tr>
<th>Age</th>
<th>Conventional Units</th>
<th>SI Units (Conventional Units × 0.01)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Newborn</td>

<td>200–400 mg/dL</td>
<td>2.00–4.00 g/L</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Fibrinogen (factor I) is synthesized in the liver. In the common final pathway of the coagulation sequence, thrombin converts fibrinogen to fibrin, which then clots blood as it combines with platelets. In normal, healthy individuals, the serum should contain no residual fibrinogen after clotting has occurred.

**INDICATIONS:**
- Assist in the diagnosis of suspected disseminated intravascular coagulation (DIC), as indicated by decreased fibrinogen levels
- Evaluate congenital or acquired dysfibrinogenemias
- Monitor hemostasis in disorders associated with low fibrinogen levels or elevated levels that can predispose patients to excessive thrombosis

**RESULT:**

*Increased in:*
- Inflammatory conditions
- Acute myocardial infarction
- Cancer

*Decreased in:
- Congenital fibrinogen deficiency (rare) *(Related to deficient synthesis)*
- DIC *(Fibrinogen is converted to fibrin)*
- Dysfibrinogenemia *(Inherited abnormality in fibrinogen synthesis)*
- Liver disease (severe) *(Related to decreased synthesis)*
- Primary fibrinolysis *(During fibrinolysis plasmin breaks down fibrinogen and fibrin)*

**CRITICAL VALUES:**

*Less than 80 mg/dL

Note and immediately report to the health care provider (HCP) any critically decreased values and related symptoms. Signs and symptoms of microvascular thrombosis include cyanosis, ischemic tissue necrosis, hemorrhagic necrosis, tachypnea, dyspnea, pulmonary emboli, venous distention, abdominal pain, and...*
FIBRINOGEN

oliguria. Possible interventions include identification and treatment of the underlying cause, support through administration of required blood products (platelets, cryoprecipitate, or fresh frozen plasma), and administration of heparin.

INTERFERING FACTORS:

• Drugs that may increase fibrinogen levels include acetylsalicylic acid, norethandrolone, oral contraceptives, oxandrolone, and oxymetholone.
• Drugs that may decrease fibrinogen levels include anabolic steroids, asparaginase, bezafibrate, danazol, dextran, fenofibrate, fish oils, gemfibrozil, lovastatin, pentoxifylline, phosphorus, and ticlopidine.
• Transfusions of whole blood, plasma, or fractions within 4 wk of the test invalidate results.
• Placement of tourniquet for longer than 1 min can result in venous stasis and changes in the concentration of plasma proteins to be measured. Platelet activation may also occur under these conditions, causing erroneous results.
• Vascular injury during phlebotomy can activate platelets and coagulation factors, causing erroneous results.
• Hemolyzed specimens must be rejected because hemolysis is an indication of platelet and coagulation factor activation.
• Incompletely filled tubes contaminated with heparin or clotted specimens must be rejected.
• Icteric or lipemic specimens interfere with optical testing methods, producing erroneous results.
• Traumatic venipuncture and excessive agitation of the sample can alter test results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➧ Inform the patient that the test is used to evaluate fibrinolytic activity as well as identify congenital deficiency and disseminated intravascular coagulation (DIC).
➧ Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
➧ Obtain a history of the patient’s hematopoietic and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
➧ Note any recent procedures that can interfere with test results.
➧ Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
➧ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern or modesty, is important in providing psychological support before, during, and after the procedure.
➧ There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

➧ If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
➧ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
➧ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate
tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL blue-top tube. Fill the tube completely. **Important note:** Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It is important to ask the laboratory which concentration it recommends, because each concentration will have its own specific reference range.

When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and nonadditive red-top tubes. When coagulation testing is the only work to be done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with tissue thromboplastin, which can falsely decrease values.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed specimens stored in unopened tubes is that testing should be completed within 1 to 4 hr of collection.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to report bruising, petechiae, and bleeding from mucous membranes, hematuria and occult blood.
- Inform the patient with a decreased fibrinogen level of the importance of taking precautions against bruising and bleeding, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of acetylsalicylic acid and similar products, and avoidance of intramuscular injections.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ALT, albumin, ALP, AT-III, AST, bilirubin, biopsy bone, biopsy bone marrow, biopsy liver, clot retraction, coagulation factors, complete blood count, platelet count, CT cardiac scoring, CK and isoenzymes, CRP, D-dimer, echocardiography, echocardiography transesophageal, ECG, ESR, exercise stress test, FDP, GGT, Holter monitor, IFE, immunoglobulins, myocardial perfusion heart scan, aPTT, plasminogen, protein S, and PT/INR.
- Refer to the Hematopoietic and Hepatobiliary System tables at the back of the book for related tests by body system.
Fluorescein Angiography

SYNONYM/ACRONYM: FA.

AREA OF APPLICATION: Eyes.

CONTRAST: Fluorescein dye.

DESCRIPTION: Fluorescein angiography (FA) involves the color radiographic examination of the retinal vasculature following rapid IV injection of a sodium fluorescein contrast medium. A special camera allows images to be taken in sequence and manipulated by a computer to provide views of the retinal vessels during filling and emptying of the dye. The camera allows only light waves in the blue range to strike the fundus of the eye. When the fluorescein reaches the blood vessels in the eye, blue light excites the dye molecules to a higher state of activity and causes them to emit a greenish-yellow fluorescence that is recorded.

INDICATIONS:
- Detect arterial or venous occlusion evidenced by the reduced, delayed, or absent flow of the contrast medium through the vessels or possible vessel leakage of the medium
- Detect possible vascular disorders affecting visual acuity
- Detect presence of microaneurysms caused by hypertensive retinopathy
- Detect the presence of tumors, retinal edema, or inflammation, as evidenced by abnormal patterns or degree of fluorescence
- Diagnose diabetic retinopathy
- Diagnose past reduced flow or patency of the vascular circulation of the retina, as evidenced by neovascularization
- Diagnose presence of macular degeneration and any other degeneration and any associated hemorrhaging
- Observe ocular effects resulting from the long-term use of high-risk medications

RESULT:
Normal findings in:
- No leakage of dye from retinal blood vessels
- Normal retina and retinal and choroidal vessels
- No evidence of vascular abnormalities, such as hemorrhage, retinopathy, aneurysms, or obstructions caused by stenosis and resulting in collateral circulation

Abnormal findings in:
- Aneurysm
- Arteriovenous shunts
- Diabetic retinopathy
- Macular degeneration
- Neovascularization
- Obstructive disorders of the arteries or veins that lead to collateral circulation

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients with a past history of hypersensitivity to radiographic dyes

Access additional resources at davisplus.fadavis.com
- Patients with narrow-angle glaucoma if pupil dilation is performed; dilation can initiate a severe and sight-threatening open-angle attack.
- Patients with allergies to mydriatics if pupil dilation using mydriatics is performed.

Factors that may impair the results of the examination:
- Inability of the patient to cooperate or remain still during the test because of age, significant pain, or mental status may interfere with the test results.
- Presence of cataracts may interfere with fundal view.
- Ineffective dilation of the pupils may impair clear imaging.
- Allergic reaction to radiographic dye, including nausea and vomiting.
- Failure to follow medication restrictions before the procedure may cause the procedure to be canceled or repeated.

Nursing Implications and Procedure

Pretest:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test detects possible vascular disorders of the eye.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to radiographic dyes, shellfish, and bee venom.
- Obtain a history of the patient’s known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; and eye conditions with treatment regimens.
- Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Instruct the patient to remove contact lenses or glasses, as appropriate.
- Instruct the patient regarding the importance of keeping the eyes open for the test.
- Review the procedure with the patient. Explain that the patient will be requested to fixate the eyes during the procedure. Address concerns about pain and explain that mydriatics, if used, may cause blurred vision and sensitivity to light. There may also be a brief stinging sensation when the drop is put in the eye. Explain to the patient that some discomfort may be experienced during the insertion of the IV. Inform the patient that, when fluorescein dye is injected, it may cause facial flushing or nausea and vomiting. Inform the patient that a health care provider (HCP) performs the test, in a quiet, darkened room, and that to dilate and evaluate both eyes, the test can take up 60 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line will be inserted to allow intermittent infusion of dye.
- There are no food or fluid restrictions, unless by medical direction.
- The patient should avoid eye medications (particularly mydriatic eye drops if the patient has glaucoma) for at least 1 day prior to the test.
- Ensure that the patient understands that he or she must refrain from driving until the pupils return to normal (about 4 hr) after the test and has made arrangements to have someone else be responsible for transportation after the test.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

Intratest:
- Ensure that the patient has complied with medication restrictions; assure that eye medications, especially mydriatics, have been withheld for at least 1 day prior to the test.
- Have emergency equipment readily available.
Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still during the procedure because movement produces unreliable results.

Seat the patient in a chair that faces the camera. Instruct the patient to look at directed target while the eyes are examined.

If dilation is to be performed, administer the ordered mydriatic to each eye and repeat in 5 to 15 min. Drops are placed in the eye with the patient looking up and the solution directed at the six o’clock position of the sclera (white of the eye) near the limbus (grey, semi-transparent area of the eyeball where the cornea and sclera meet). Neither dropper nor bottle should touch the eyelashes.

Insert an intermittent infusion device, as ordered, for subsequent injection of the contrast media or emergency medications.

After the eyedrops are administered but before the dye is injected, color fundus photographs are taken.

Instruct the patient to place the chin in the chin rest and gently press the forehead against the support bar. Instruct the patient to open his or her eyes wide and look at the desired target.

Fluorescein dye is injected into the brachial vein using the intermittent infusion device, and a rapid sequence of photographs are taken and repeated after the dye has reached the retinal vascular system. Follow-up photographs are taken in 20 to 30 min.

At the conclusion of the procedure, remove the IV needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Observe for hypersensitive reaction to the dye. The patient may become nauseous and vomit.

POST-TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual medications, as directed by the HCP.

Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss or anticipated loss of driving privileges. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information regarding vision aids, if desired, for ABLEDATA (sponsored by the National Institute on Disability and Rehabilitation Research [NIDRR], available at www.abledata.com). Information can also be obtained from the American Macular Degeneration Foundation (www.macular.org), the Glaucoma Research Foundation (www.glaucoma.org), and the American Diabetes Association (www.diabetes.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that visual acuity and responses to light may change. Suggest that the patient wear dark glasses after the test until the pupils return to normal size. Inform the patient that yellow discoloration of the skin and urine from the radiographic dye is normally present for up to 2 days. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include fructosamine, fundus photography, glucagon, glucose, glycated hemoglobin, gonioscopy, insulin, intraocular pressure, microalbumin, plethysmography, refraction, slit-lamp biomicroscopy, and visual field testing.

Refer to the Ocular System table at the back of the book for related tests by body system.
Folate

SYNONYM/ACRONYM: Folic acid, Vitamin B<sub>9</sub>.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Radioimmunoassay)

<table>
<thead>
<tr>

<td>Greater than 5.7 nmol/L</td>
</tr>
</tbody>
</table>

DESCRIPTION: Folate, a water-soluble vitamin, is produced by bacteria in the intestines and stored in small amounts in the liver. Dietary folate is absorbed through the intestinal mucosa and stored in the liver. Folate is necessary for normal red blood cell and white blood cell function, DNA replication, and cell division. Folate levels are often measured in association with serum vitamin B<sub>12</sub> determinations since vitamin B<sub>12</sub> is required for folate to enter tissue cells. Folate is an essential coenzyme in the conversion of homocysteine to methionine. Hyperhomocysteinemia resulting from folate deficiency in pregnant women is believed to increase the risk of neural tube defects. Hyperhomocysteinemia related to low folate acid levels is also associated with increased risk for cardiovascular disease.

- Monitor the effects of prolonged parenteral nutrition
- Monitor response to disorders that may lead to folate deficiency or decreased absorption and storage

RESULT:

*Increased in:*
- Blind loop syndrome *(Malabsorption in a segment of the intestine due to competition for absorption of folate produced by bacterial overgrowth)*
- Excessive dietary intake of folate or folate supplements
- Pernicious anemia *(Inadequate levels of vitamin B<sub>12</sub>, due to impaired absorption, result in increased circulating folate levels)*
- Vitamin B<sub>12</sub> deficiency *(Inadequate levels of vitamin B<sub>12</sub> to metabolize folate result in increased circulating folate levels)*

*Decreased in:*
- Chronic alcoholism *(Insufficient intake combined with malabsorption)*
- Crohn’s disease *(Related to malabsorption)*
- Exfoliative dermatitis *(Related to increased demand)*
• Hemolytic anemias *(Increased demand related to shortened RBC life span as the result of folate deficiency)*
• Liver disease *(Related to increased excretion)*
• Malnutrition *(Insufficient intake)*
• Megaloblastic anemia *(Folate deficiency affects development of the RBC and results in anemia)*
• Myelofibrosis *(Related to increased demand)*
• Neoplasms *(Related to increased demand)*
• Pregnancy *(Related to increased demand possibly combined with insufficient dietary intake)*
• Regional enteritis *(Related to malabsorption)*
• Scurvy *(Insufficient intake)*
• Sideroblastic anemias *(As an acquired anemia resulting from folate deficiency, iron enters and accumulates in the RBC but cannot become incorporated in hemoglobin)*
• Sprue *(Related to malabsorption)*
• Ulcerative colitis *(Related to malabsorption)*
• Whipple’s disease *(Related to malabsorption)*

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
• Drugs that may decrease folate levels include aminopterin, ampicillin, antacids, anticonvulsants, barbiturates, chloramphenicol, chloroguanide, erythromycin, ethanol, glutethimide, lincomycin, metformin, methotrexate, nitrofurans, oral contraceptives, penicillin, pentamidine, phenytoin, pyrimethamine, tetracycline, and triamterene.
• Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when radioimmunoassay is the test method.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to detect folate deficiency and to monitor folate therapy.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s gastrointestinal and hematopoietic systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. Protect the specimen from light.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for
bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- **Nutritional considerations:** Instruct the folate-deficient patient (especially pregnant women), as appropriate, to eat foods rich in folate, such as liver, salmon, eggs, asparagus, green leafy vegetables, broccoli, sweet potatoes, beans, and whole wheat.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include antibodies antithyroglobulin, biopsy intestinal, capsule endoscopy, complete blood count, complete blood count, RBC indices, complete blood count, RBC morphology, complete blood count, WBC count and differential, eosinophil count, fecal analysis, gastric acid emptying scan, gastric acid stimulation test, gastrin, G6PD, hemosiderin, homocysteine, intrinsic factor antibodies, thyroid and vitamin B₁₂.
- Refer to the Gastrointestinal and Hematopoietic System tables at the back of the book for related tests by body system.

---

**Follicle-Stimulating Hormone**

**SYNONYM/ACRONYM:** Follitropin, FSH.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** (Method: Immunoassay)

FOLLICLE-STIMULATING HORMONE

DESCRIPTION: Follicle-stimulating hormone (FSH) is produced and stored in the anterior portion of the pituitary gland. In women, FSH promotes maturation of the graafian (germinal) follicle, causing estrogen secretion and allowing the ovum to mature. In men, FSH partially controls spermatogenesis, but the presence of testosterone is also necessary. Gonadotropin-releasing hormone secretion is stimulated by a decrease in estrogen and testosterone levels. Gonadotropin-releasing hormone secretion stimulates FSH secretion. FSH production is inhibited by an increase in estrogen and testosterone levels. FSH production is pulsatile, episodic, and cyclic, and is subject to diurnal variation. Serial measurement is often required.

INDICATIONS:
• Assist in distinguishing between primary and secondary (pituitary or hypothalamic) gonadal failure
• Define menstrual cycle phases as a part of infertility testing
• Evaluate ambiguous sexual differentiation in infants
• Evaluate early sexual development in girls younger than age 9 or boys younger than age 10 (precocious puberty associated with elevated levels)
• Evaluate failure of sexual maturation in adolescence
• Evaluate testicular dysfunction
• Investigate impotence, gynecomastia, and menstrual disturbances

RESULT:

Increased in:
• Alcoholism (Related to suppressed secretion from the pituitary gland)

Decreased in:
• Anorexia nervosa (Related to suppressive effects of severe caloric restriction on the hypothalamic-pituitary axis)
• Anterior pituitary hypofunction (Underproduction resulting from dysfunctional pituitary gland)
Hemochromatosis (Hypogonadotropic hypogonadism related to absence of the gonadal stimulating pituitary hormones, estrogen, and testosterone; iron deposits in pituitary may affect normal production of FSH)

- Hypoprolactinemia (Related to suppressive effect on estrogen production)
- Hypothalamic disorders (Decreased production in response to lack of hypothalamic stimulators)
- Polycystic ovary disease (Stein-Leventhal syndrome) (Suppressed secretion related to feedback mechanism involving increased estrogen levels)
- Pregnancy (Related to elevated estrogen levels)
- Sickle cell anemia (Although primary testicular dysfunction is mainly associated with sickle cell disease, related to testicular microinfarcts, hypogonadotropic hypogonadism has been reported in some men with sickle cell disease)

Critical Values: N/A

Interfering Factors:
- Drugs that may increase FSH levels include cimetidine, clomiphene, digitalis, gonadotropin-releasing hormone, ketoconazole, levodopa, nafarelin, naloxone, nilutamide, oxcarbazepine, and pravastatin.
- Drugs that may decrease FSH levels include anabolic steroids, anticonvulsants, buserelin, estrogens, corticotropin-releasing hormone, goserelin, megestrol, mestranol, oral contraceptives, phenothiazine, pimozide, pravastatin, progesterone, stanozolol, tamoxifen, toremifene, and valproic acid.
- In menstruating women, values vary in relation to the phase of the menstrual cycle. Values are higher in postmenopausal women.

Nursing Implications and Procedure

Pretest:
- Inform the patient that the test is used to distinguish primary causes of gonadal failure from secondary causes, evaluate menstrual disturbances, and assist in infertility evaluations.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine and reproductive systems, as well as phase of menstrual cycle, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient ID.
FRUCTOSAMINE

Fructosamine

SYNONYM/ACRONYM: Glycated albumin.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Spectrophotometry)

DESCRIPTION: Fructosamine is the result of a covalent linkage between glucose and albumin or other proteins. Similar to glycated hemoglobin, fructosamine can be used to monitor long-term control of glucose in diabetics. It has a shorter half-life.

POST-TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Social and cultural considerations: Recognize anxiety related to test results and provide a supportive, non-judgmental environment when assisting a patient through the process of fertility testing. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient and partner regarding access to counseling services, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that multiple specimens may be required. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include antibodies, antisperm, BMD, chlamydia group antibody, chromosome analysis, CT pituitary, estradiol, laparoscopy gynecologic, LH, MRI pituitary, prolactin, testosterone, semen analysis, and US scrotal.
- Refer to the Endocrine and Reproductive System tables at the back of the book for related tests by body system.
than glycated hemoglobin and is thought to be more sensitive to short-term fluctuations in glucose concentrations. Some glycated hemoglobin methods are affected by hemoglobin variants. Fructosamine is not subject to this interference.

**INDICATIONS:**
Evaluate diabetic control

**RESULT:**
**Increased in:**
Diabetic patients with poor glucose control

**Decreased in:**
Severe hypoproteinemia

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase fructosamine levels include bendrofluamide and captopril.
- Drugs that may decrease fructosamine levels include ascorbic acid, pyridoxine, and terazosin.
- Decreased albumin levels may result in falsely decreased fructosamine levels.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate diabetic control.
- Obtain a history of the patient’s complaints, especially related to diabetic control. Obtain a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine and gastrointestinal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergy reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Nutritional considerations: Abnormal fructosamine levels may be associated with conditions resulting from poor glucose control. Instruct the diabetic patient, as appropriate, in nutritional management of the disease. Patients who adhere to dietary recommendations report a better general feeling of health, better

**INDICATIONS:**
Evaluate diabetic control

**RESULT:**
**Increased in:**
Diabetic patients with poor glucose control

**Decreased in:**
Severe hypoproteinemia

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase fructosamine levels include bendrofluamide and captopril.
- Drugs that may decrease fructosamine levels include ascorbic acid, pyridoxine, and terazosin.
- Decreased albumin levels may result in falsely decreased fructosamine levels.
weight management, greater control of glucose and lipid values, and improved use of insulin. There is no “diabetic diet”; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association. The nutritional needs of each diabetic patient must be determined individually with the appropriate health care professionals, particularly professionals trained in nutrition.

Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).

Recognize anxiety related to test results, and be supportive of impaired activity related to perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, as appropriate, that good control of glucose levels delays the onset and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Diabetes Association (www.diabetes.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include CT cardiac scoring, cortisol, C-peptide, fecal fat, fluorescein angiography, fundus photography, gastric emptying scan, glucagon, glucose, GTT, glycated hemoglobin, insulin, insulin antibodies, intraocular pressure, ketones, microalbumin, slit-lamp biomicroscopy, and visual fields testing.

- Refer to the Endocrine and Gastrointestinal System tables at the back of the book for related tests by body system.

**SYNONYM/ACRONYM:** N/A.

**AREA OF APPLICATION:** Eyes.

**CONTRAST:** N/A.

**DESCRIPTION:** This test involves the photographic examination of the structures of the eye to document the condition of the eye, detect abnormalities, and assist in following the progress of treatment.

**INDICATIONS:**

- Detect the presence of choroidal nevus
- Detect various types and stages of glaucoma
- Document the presence of diabetic retinopathy
- Document the presence of macular degeneration and any other
degeneration and any associated hemorrhaging
• Observe ocular effects resulting from the long-term use of high-risk medications

RESULT:

Normal findings in:
• Normal optic nerve and vessels
• No evidence of other ocular abnormalities

Abnormal findings in:
• Aneurysm
• Choroidal nevus
• Diabetic retinopathy
• Macular degeneration
• Obstructive disorders of the arteries or veins that lead to collateral circulation

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with narrow-angle glaucoma if pupil dilation is performed; dilation can initiate a severe and sight-threatening open-angle attack
• Patients with allergies to mydriatics if pupil dilation using mydriatics is performed

Factors that may impair the results of the examination:
• Inability of the patient to cooperate or remain still during the test because of age, significant pain, or mental status may interfere with the test results.
• Presence of cataracts may interfere with fundal view.
• Ineffective dilation of the pupils may impair clear imaging.
• Rubbing or squeezing the eyes may affect results.
• Failure to follow medication restrictions before the procedure may cause the procedure to be canceled or repeated.

PRETEST:

• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient the procedure detects possible vascular or other structural abnormalities of the eye.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially mydriatics if dilation is to be performed.
• Obtain a history of the patient’s known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; and eye conditions with treatment regimens.
• Obtain a history of results of previously performed laboratory tests and diagnostic and surgical procedures.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Instruct the patient to remove contact lenses or glasses, as appropriate.
• Instruct the patient regarding the importance of keeping the eyes open for the test.
• Review the procedure with the patient. Explain that the patient will be requested to fixate the eyes during the procedure. Address concerns about pain and explain that mydriatics, if used, may cause blurred vision and sensitivity to light. There may also be a brief stinging sensation when the drop is put in the eye but that no discomfort will be experienced during the examination.
• Inform the patient that a health care provider (HCP) performs the test, in a quiet, darkened room, and that to dilate and evaluate both eyes, the test can take up 60 min.
• Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• There are no food or fluid restrictions, unless by medical direction.
• The patient should avoid eye medications (particularly mydriatic eye drops if the patient has glaucoma) for at least 1 day prior to the test.
Ensure that the patient understands that he or she must refrain from driving until the pupils return to normal (about 4 hr) after the test and has made arrangements to have someone else be responsible for transportation after the test.

**INTRATEST:**

- Ensure that the patient has complied with medication restrictions; assure that eye medications, especially mydriatics, have been restricted for at least 1 day prior to the test.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still during the procedure because movement produces unreliable results.
- Seat the patient in a chair that faces the camera. Instruct the patient to look at directed target while the eyes are examined.
- If dilation is to be performed, administer the ordered mydriatic to each eye and repeat in 5 to 15 min. Drops are placed in the eye with the patient looking up and the solution directed at the six o’clock position of the sclera (white of the eye) near the limbus (grey, semi-transparent area of the eyeball where the cornea and sclera meet). Neither dropper nor bottle should touch the eyelashes.
- Instruct the patient to place the chin in the chin rest and gently press the forehead against the support bar. Instruct the patient to open his or her eyes wide and look at desired target while a sequence of photographs are taken.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual medications, as directed by the HCP.
- Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss or anticipated loss of driving privileges. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information regarding vision aids, if desired, for ABLEDATA (sponsored by the National Institute on Disability and Rehabilitation Research [NIDRR], available at www.abledata.com). Information can also be obtained from the American Macular Degeneration Foundation (www.macular.org) and the American Diabetes Association (www.diabetes.org).
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that visual acuity and responses to light may change. Suggest that the patient wear dark glasses after the test until the pupils return to normal size. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include fluorescein angiography, fructosamine, glucagon, glucose, glycated hemoglobin, gonioscopy, insulin, intraocular pressure, microalbumin, intraocular pressure, microalbumin, plethysmography, refraction, slit-lamp biomicroscopy, and visual field testing.
- Refer to the table of tests associated with the Ocular System at the back of the book for related tests by body system.
SYNONYM/ACRONYM: Ga; Gallium scan, tumor; gallium scan, abscess; gallium scan, fever of undetermined origin.

AREA OF APPLICATION: Whole body.

CONTRAST: IV radioactive gallium-67 citrate.

DESCRIPTION: Gallium imaging is a nuclear medicine study that assists in diagnosing neoplasm and inflammation activity. Gallium, which has 90% sensitivity for inflammatory disease, is readily distributed throughout plasma and body tissues. Gallium imaging is sensitive in detecting abscesses, pneumonia, pyelonephritis, active sarcoidosis, and active tuberculosis. In immunocompromised patients, such as patients with AIDS, gallium imaging can detect complications such as Pneumocystis jiroveci (formerly carinii) pneumonitis. Gallium imaging is useful but less commonly performed in the diagnosis and staging of some neoplasms, including Hodgkin’s disease, lymphoma, melanoma, and leukemia. Imaging can be performed 6 to 72 hr after gallium injection. A gamma camera detects the radiation emitted from the injected radioactive material, and a representative image of the distribution of the radioactive material is obtained. The nonspecificity of gallium imaging requires correlation with other diagnostic studies, such as computed tomography, magnetic resonance imaging, and ultrasonography.

INDICATIONS:
• Aid in the diagnosis of infectious or inflammatory diseases
• Evaluate lymphomas

• Evaluate recurrent lymphomas or tumors after radiation therapy or chemotherapy
• Perform as a screening examination for fever of undetermined origin

RESULT:
Normal findings in:
• Normal distribution of gallium. Some localization of the radionuclide within the liver, spleen, bone, nasopharynx, lacrimal glands, breast, and bowel is expected.

Abnormal findings in:
• Abscess
• Infection
• Inflammation
• Lymphoma
• Tumor

CRITICAL VALUES: N/A

INTERFERING FACTORS:
This procedure is contraindicated for:
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
Performance of other nuclear scans within the preceding 24 to 48 hr
Administration of certain medications (e.g., gastrin, cholecystokinin), which may interfere with gastric emptying

Other considerations:
Improper injection of the radionuclide may allow the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test detects inflammation, infection, or tumor.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- Obtain a history of the patient’s immune, musculoskeletal, and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department, by a HCP specializing in this procedure, with support staff, and takes approximately 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
There are no food, fluid, or medication restrictions, unless by medical direction.
Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into
the gown, robe, and foot coverings provided.

- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to lie still during the procedure because movement produces unclear images.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in a supine position on a flat table with foam wedges, which help maintain position and immobilization.
- IV radionuclide is administered and the patient is instructed to return for scanning at a designated time after injection. Typical scanning occurs at 6, 24, 48, 72, 96, and/or 120 hr postinjection depending on diagnosis.
- If an abdominal abscess or infection is suspected, laxatives or enemas may be ordered before imaging at 48 or 72 hr after the injection.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- Remove the needle or catheter and apply a pressure dressing over the puncture site.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- Instruct the patient to resume usual medication, or activity, as directed by the HCP.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the injection site. Observe for bleeding, hematoma formation, and inflammation.
- If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- Instruct the patient to immediately flush the toilet, and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- Instruct all caregivers to wear gloves when discarding urine for 48 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash ungloved hands after removing the gloves.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include angiotensin converting enzyme, biopsy bone marrow, biopsy kidney, biopsy lung, blood gases, bronchoscopy, complete blood count, chest x-ray, CT abdomen, CT pelvis, CT thoracic, culture blood, culture and smear mycobacteria, culture viral, cytology sputum, cytology urine, ESR, HIV-1/2 antibodies, IVP, lung perfusion scan, MRI chest, MRI abdomen, mediastinoscopy, pleural fluid analysis, plethysmography, PFT, pulse oximetry, renogram, US kidney, and US lymph node.
- Refer to the Immune, Musculoskeletal, and Respiratory System tables in the back of the book for related tests by body system.
**Gastric Acid Stimulation Test**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Gastric fluid collected in eight plastic tubes at 15-min intervals.

**REFERENCE VALUE:** (Method: Volume measurement and pH by ion-selective electrode)

### Basal acid output (BAO)
- **Male:** 0–10.5 mmol/hr
- **Female:** 0–5.6 mmol/hr

### Peak acid output (PAO)
- **Male:** 12–60 mmol/hr
- **Female:** 8–40 mmol/hr

### Peak response time
- **Pentagastrin, intramuscular:** 15–45 min
- **Pentagastrin, subcutaneous:** 10–30 min

### BAO/PAO ratio
- Less than 0.20

**DESCRIPTION:** The gastric acid stimulation test is performed to determine the response to substances administered to induce increased gastric acid production. Pentagastrin is the usual drug of choice to induce gastric secretion because it has no major side effects. The samples obtained from gastric acid stimulation tests are examined for volume, pH, and amount of acid secreted. First, basal acid output (BAO) is determined by averaging the results of gastric samples collected before the administration of a gastric stimulant. Then a gastric stimulant is administered and peak acid output (PAO) is determined by adding together the gastric acid output of the highest two consecutive 15-min stimulation samples. Finally, BAO and PAO are compared as a ratio, which is normally less than 0.20.

**INDICATIONS:**
- Detect duodenal ulcer
- Detect gastric carcinoma
- Detect pernicious anemia
- Detect Zollinger-Ellison syndrome
- Evaluate effectiveness of vagotomy in the treatment of peptic ulcer disease

**RESULT:**

*Increased in:*

Any alteration in the balance between the digestive and protective functions of the stomach that increases gastric acidity, e.g., hypersecretion of gastrin, use of NSAIDs or *Helicobacter pylori* infection.

*Increased:*
- BAO
  - Basophilic leukemia
  - Duodenal ulcer
  - G-cell hyperplasia
  - Recurring peptic ulcer
  - Retained antrum syndrome
  - Systemic mastocytosis
Vagal hyperfunction
Zollinger-Ellison syndrome

• PAO
Duodenal ulcer
Zollinger-Ellison syndrome

**Decreased in:**
Conditions that result in the gradual loss of function of the antrum and G-cells, where gastrin is produced, will reflect decreased gastrin levels.

**Decreased:**
• BAO
Gastric ulcer

• PAO
Chronic gastritis
Gastric cancers
Gastric polyps
Gastric ulcer
Myxedema
Pernicious anemia

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
• Drugs that may increase gastric volume include atropine, diazepam, ganglionic blocking agents, and insulin.
• Drugs and substances that may increase gastric pH include caffeine, calcium salts, corticotropin, ethanol, rauwolfia, reserpine, and tolazoline.
• Drugs and substances that may decrease gastric pH include atropine, cimetidine, diazepam, famotidine, ganglionic blocking agents, glucagon, nizatidine, omeprazole, oxmetidine, propranolol, prostaglandin F$_{2a}$, ranitidine, and secretin.
• Gastric intubation is contraindicated in patients with esophageal varices, diverticula, stenosis, malignant neoplasm of the esophagus, aortic aneurysm, severe gastric hemorrhage, and congenital heart failure.
• The use of histamine diphosphate is contraindicated in patients with a history of asthma, paroxysmal hypertension, urticaria, or other allergic conditions.
• Failure to follow dietary restrictions may result in stimulation of gastric secretions.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
• Exposure to the sight, smell, or thought of food immediately before and during the test may result in stimulation of gastric secretions.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRE-TEST:**
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to assist in the differential diagnosis of gastrointestinal disorders.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Inform the patient that specimen collection takes approximately 60 to 120 min. Address concerns about pain and explain that some discomfort is experienced from insertion of the nasogastric tube.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• Drugs and substances that may alter gastric secretions (e.g., alcohol, histamine, nicotine, adrenocorticotropic
steroids, insulin, parasympathetic agents, belladonna alkaloids, anticholinergic drugs, histamine receptor antagonists) should be restricted by medical direction for 72 hr before the test. Instruct the patient to fast from food after the evening meal the night before the test, and not to drink water for 1 hr before the test. Instruct the patient to refrain from the use of chewing gum or tobacco products for at least 12 hr prior to and for the duration of the test. Protocols may vary from facility to facility. Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**
- Ensure that the patient has complied with dietary restrictions and other pretesting preparations; assure that food has been restricted for at least 12 hr prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Ensure that the patient does not have a history of asthma, paroxysmal hypertension, urticaria, or other allergic conditions if histamine diphosphate is being considered for use in the test.
- Record baseline vital signs.
- If the patient is wearing dentures, have him or her remove them.
- Ask the patient to sit, or help the patient recline on the left side.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date, and time of collection.
- A cold lubricated gastric (Levine) tube is inserted orally. Alternatively, if the patient has a hyperactive gag reflex, the tube can be inserted nasally. The tube must have a radiopaque tip.
- Fluoroscopy or x-ray is used to confirm proper position of the tube before the start of the test.
- Using a constant but gentle suction, gastric contents are collected. Do not use specimens obtained from the first 15 to 30 min of suctioning.
- The gastric stimulant is administered, and the peak basal specimens are collected over a 60-min period as four 15-min specimens. Number the specimen tubes in the order in which they were collected.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume usual diet and medication, as directed by the HCP.
- Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP for evaluation. Protocols may vary from facility to facility.
- Instruct the patient to report any chest pain, upper abdominal pain, pain on swallowing, difficulty breathing, or expectoration of blood. Report these to the HCP immediately.
- Monitor for side effects of drugs administered to induce gastric secretion (e.g., flushing, headache, nasal stuffiness, dizziness, faintness, nausea).

**Nutritional considerations:** Nutritional support with calcium, iron, and vitamin B12 supplementation may be ordered, as appropriate. Dietary modifications may include encouraging liquids and low-residue foods, eating multiple small meals throughout the day, and avoidance of foods that slow digestion such as foods high in fat and fiber. Severe cases of gastroparesis may require temporary treatments that include total parenteral nutrition or use of jejunostomy tubes.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Gastric Emptying Scan

SYNONYM/ACRONYM: Gastric emptying quantitation, gastric emptying scintigraphy.

AREA OF APPLICATION: Esophagus, stomach, small bowel.

CONTRAST: Oral radioactive technetium-99m sulfur colloid.

DESCRIPTION: A gastric emptying scan quantifies gastric emptying physiology. The procedure is indicated for patients with gastric motility symptoms, including diabetic gastroparesis, anorexia nervosa, gastric outlet obstruction syndromes, postvagotomy and postgastrectomy syndromes, and assessment of medical and surgical treatments for diseases known to affect gastric motility. A radionuclide is administered, and the clearance of solids and liquids may be evaluated. The images are recorded electronically, showing the gastric emptying function over time.

INDICATIONS:
- Investigate the cause of rapid or slow rate of gastric emptying
- Measure gastric emptying rate

RESULT:

Normal findings in:
- Mean time emptying of liquid phase: 30 min (range, 11 to 49 min)
- Mean time emptying of solid phase: 40 min (range, 28 to 80 min)
- No delay in gastric emptying rate

Abnormal findings in:
- Decreased rate:
  - Dumping syndrome
  - Duodenal ulcer
  - Malabsorption syndromes
  - Zollinger-Ellison syndrome
Increased rate:
- Amyloidosis
- Anorexia nervosa
- Diabetes
- Gastric outlet obstruction
- Gastric ulcer
- Gastroenteritis
- Gastroesophageal reflux
- Hypokalemia, hypomagnesemia
- Post–gastric surgery period
- Postoperative ileus
- Post–radiation therapy period
- Scleroderma

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
- Patients with esophageal motor disorders or swallowing difficulties

Factors that may impair clear imaging:
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Retained barium from a previous radiological procedure
- Other nuclear scans done within the previous 24 to 48 hr
- Administration of certain medications (e.g., gastrin, cholecystokinin), which may interfere with gastric emptying

Other considerations:
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation.

Access additional resources at davisplus.fadavis.com
A procedure is performed in a nuclear medicine department by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 120 min.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during and after the procedure.

Instruct the patient to restrict food and fluids for 8 hr before the scan. Protocols may vary from facility to facility.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure the patient has complied with dietary and fluid restrictions for 8 hr before the scan.
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Record baseline vital signs and neurological status. Protocols may vary from facility to facility.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to lie still during the procedure because movement produces unclear images.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in an upright position in front of the gamma camera.
- Ask the patient to take the radionuclide mixed with water or other liquid orally, or combined with eggs for a solid study.
- Images are recorded over a period of time (30 to 60 min) and evaluated with regard to the amount of time the stomach takes to empty its contents.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Advise the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- Monitor vital signs every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Compare with baseline values. Protocols may vary from facility to facility.
- Instruct the patient to resume usual diet, fluids, medication, and activity, as directed by the HCP.
- If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water after each voiding for 24 hr after the procedure.
- Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water after removing gloves. Then wash hands after removing the gloves.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

Stimulation Tests

- Gastrin stimulation test with calcium or secretin
- No response or slight increase over baseline

DESCRIPTION: Gastrin is a hormone secreted by the stomach and duodenum in response to vagal stimulation; the presence of food, alcohol, or calcium in the stomach; and the alkalinity of gastric secretions. After its absorption into the circulation, gastrin returns to the stomach and acts as a stimulant for acid, insulin, pepsin, and intrinsic factor secretion. Gastrin stimulation tests can be performed after a test meal or IV infusion of calcium or secretin.

INDICATIONS:
- Assist in the diagnosis of gastric carcinoma, pernicious anemia, or G-cell hyperplasia
- Assist in the diagnosis of Zollinger-Ellison syndrome
- Assist in the differential diagnosis of ulcers from other gastrointestinal (GI) peptic disorders

RESULT:

Increased in:
- Chronic gastritis (Related to hypersecretion of gastrin, use of NSAIDs, or Helicobacter pylori infection.)
- Chronic renal failure (*Related to inadequate renal excretion*)
- Gastric and duodenal ulcers (*Related to hypersecretion of gastrin, use of NSAIDs, or H. pylori infection.*)
- Gastric carcinoma (*Related to disturbance in pH favoring alkalinity, which stimulates gastrin production*)
- G-cell hyperplasia (*Hyperplastic G-cells produce excessive amounts of gastrin*)
- Hyperparathyroidism (*Related to hypercalcemia; calcium is a potent stimulator for the release of gastrin*)
- Pernicious anemia (*Related to antibodies against gastric intrinsic factor [66% of cases] and parietal cells [80% of cases that affect the stomach’s ability to secrete acid; achlorhydria is a strong stimulator of gastrin production]*)
- Pyloric obstruction (*Related to gastric distension, which stimulates gastrin production*)
- Retained antrum (*Remaining tissue stimulates gastrin production*)
- Zollinger-Ellison syndrome (*Gastrin-producing tumor*)

Decreased in:
- Hypothyroidism (*Related to hypocalcemia*)
- Vagotomy (*Vagus nerve impulses stimulate secretion of digestive secretions; interruptions in these nerve impulses result in decreased gastrin levels*)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may decrease gastrin levels include atropine, enprostil, glucagon, secretin, streptozocin, and tolbutamide.
- In some cases, protein ingestion elevates serum gastrin levels.
- Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when radioimmunoassay is the test method.
- Failure to follow dietary and medication restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of Zollinger-Ellison syndrome and gastrinoma.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine and GI systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to fast for 12 hr before the test. Instruct the patient to refrain from the use of chewing gum or tobacco products for at least 4 hr.
Prior to and for the duration of the test. Protocols may vary from facility to facility.

- Instruct the patient to withhold medications and alcohol for 12 to 24 hr, as ordered by the health care provider (HCP).
- There are no fluid restrictions, unless by medical direction.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure that the patient has complied with dietary and medication restrictions and other pretesting preparations; assure that food and medications have been withheld for at least 4 and 12 hr, respectively prior to the procedure. The patient should be reminded to refrain from use of chewing gum or tobacco products during the test.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Administer gastrin stimulators as appropriate.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet and medications, as directed by the HCP.

**Nutritional considerations:** Nutritional support with calcium, iron, and vitamin B₁₂ supplementation may be ordered, as appropriate. Dietary modifications may include encouraging liquids and low-residue foods, eating multiple small meals throughout the day, and avoidance of foods that slow digestion such as foods high in fat and fiber. Severe cases of gastroparesis may require temporary treatments that include total parental nutrition or use of jejunostomy tubes.

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
- Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in the significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include capsule endoscopy, complete blood count, complete blood count, RBC indices, complete blood count, RBC morphology, complete blood count, WBC count and differential, esophagogastroduodenoscopy, fecal analysis, folate, gastric acid stimulation test, gastric emptying scan, *H. pylori* antibody, intrinsic factor antibodies, upper GI series, and vitamin B₁₂.
- Refer to the Endocrine and Gastrointestinal System tables at the back of the book for related tests by body system.
Gastroesophageal Reflux Scan

SYNONYM/ACRONYM: Aspiration scan, GER scan, GERD scan.

AREA OF APPLICATION: Esophagus and stomach.

CONTRAST: Oral radioactive technetium-99m sulfur colloid.

DESCRIPTION: The gastroesophageal reflux (GER) scan assesses gastric reflux across the esophageal sphincter. Symptoms of GER include heartburn, regurgitation, vomiting, dysphagia, and a bitter taste in the mouth. This procedure may be used to evaluate the medical or surgical treatment of patients with GER and to detect aspiration of gastric contents into the lungs. A radionuclide such as technetium-99m sulfur colloid is ingested orally in orange juice. Scanning studies are done immediately to assess the amount of liquid that has reached the stomach. An abdominal binder is applied and then tightened gradually to obtain images at increasing degrees of abdominal pressure: 0, 20, 40, 60, 80, and 100 mm Hg. Computer calculation determines the amount of reflux into the esophagus at each of these abdominal pressures as recorded on the images. For aspiration scans, images are taken over the lungs to detect tracheoesophageal aspiration of the radionuclide.

In infants, the study distinguishes between vomiting and reflux. Reflux occurs predominantly in infants younger than age 2, who are mainly on a milk diet. This procedure is indicated when an infant has symptoms such as failure to thrive, feeding problems, and episodes of wheezing with chest infection. The radionuclide is added to the infant’s milk, images are obtained of the gastric and esophageal area, and the images are evaluated visually and by computer.

INDICATIONS:
• Aid in the diagnosis of GER in patients with unexplained nausea and vomiting
• Distinguish between vomiting and reflux in infants with failure to thrive, feeding problems, and wheezing combined with chest infection

RESULT:
Normal findings in:
• Reflux less than or equal to 4% across the esophageal sphincter

Abnormal findings in:
• Reflux of greater than 4% at any pressure level
• Pulmonary aspiration

CRITICAL VALUES: N/A

INTERFERING FACTORS:
This procedure is contraindicated for:
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
Patients with hiatal hernia, esophageal motor disorders, or swallowing difficulties

**Factors that may impair clear imaging:**
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Metallic objects (e.g., jewelry, body rings, dentures) within the examination field, which may inhibit organ visualization and cause unclear images
- Retained barium from a previous radiological procedure
- Other nuclear scans done within the previous 24 to 48 hr

**Other considerations:**
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation.

**Obtain a history of the patient’s complaints, including a list of known allergens (especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes).**

**Obtain a history of the patient’s GI system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.**

**Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.**

**Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.**

**Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.**

**Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.**

**Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.**

**Instruct the patient to remove jewelry and other metallic objects from the area to be examined.**

**There are no food or fluid restrictions, unless by medical direction.**

**Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

**INTRATEST:**
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure evaluates gastric reflux.

Access additional resources at davisplus.fadavis.com
Record baseline vital signs and assess neurological status. Protocols may vary from facility to facility.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Administer a sedative to a child or to an uncooperative adult, as ordered.

Place the patient in an upright position and instruct them to ingest the radionuclide combined with orange juice.

Place the patient in a supine position on a flat table 15 min after ingestion.

An abdominal binder with an attached sphygmomanometer is applied, and scans are taken as the binder is tightened at various pressures.

If reflux occurs at lower pressures, an additional 30 mL of water may be given to clear the esophagus.

Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

POST-TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Advise the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hr.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Compare with baseline values. Protocols may vary from facility to facility.

Instruct the patient to resume usual diet, fluids, medication, and activity, as directed by the HCP.

No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.

If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.

Instruct the patient to immediately flush the toilet, and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.

Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.

Nutritional considerations: A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes. High fat consumption increases the amount of bile acids in the colon and should be avoided.

Recognize anxiety related to test results, and be supportive of expected changes in lifestyle. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include CT abdomen, esophageal manometry, gastric emptying scan, and upper GI series.

Refer to the Gastrointestinal and Musculoskeletal System tables in the back of the book for related tests by body system.
Gastrointestinal Blood Loss Scan

**SYNONYM/ACRONYM:** Gastrointestinal bleed localization study, GI bleed scintigraphy, lower GI blood loss scan, GI scintigram.

**AREA OF APPLICATION:** Abdomen.

**CONTRAST:** IV radioactive technetium-99m–labeled red blood cells.

**DESCRIPTION:** Gastrointestinal (GI) blood loss scan is a nuclear medicine study that assists in detecting and localizing active GI tract bleeding (2 or 3 mL/min) for the purpose of better directing endoscopic or angiographic studies. This procedure can detect bleeding if the rate is greater than 0.5 mL/min, but it is not specific for site localization or cause of bleeding. Endoscopy is the procedure of choice for diagnosing upper GI bleeding. After injection of technetium-99m–labeled red blood cells, immediate and delayed images of various views of the abdomen are obtained. The radionuclide remains in the circulation long enough to extravasate and accumulate within the bowel lumen at the site of active bleeding. This procedure is valuable for the detection and localization of recent non–GI intra-abdominal hemorrhage. Images may be taken over an extended period to show intermittent bleeding.

**RESULT:**

**Normal findings in:**
- Normal distribution of radionuclide in the large vessels with no extravascular activity

**Abnormal findings in:**
- Angiodysplasia
- Aortoduodenal fistula
- Diverticulosis
- GI bleeding
- Inflammatory bowel disease
- Polyps
- Tumor
- Ulcer

**CRITICAL VALUES:**
- Acute GI bleed
- Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

**INTERFERING FACTORS:**

*This procedure is contraindicated for:*
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

*Factors that may impair clear imaging:*
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

**INDICATIONS:**
- Diagnose unexplained abdominal pain and GI bleeding
• Retained barium from a previous radiological procedure
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
• Other nuclear scans done within the previous 24 to 48 hr
• Inaccurate timing of imaging after the radionuclide injection

**Other considerations:**
• The examination detects only active or intermittent bleeding.
• The procedure is of little value in patients with chronic anemia or slowly decreasing hematocrit.
• The scan is less accurate for localization of bleeding sites in the upper GI tract.
• Improper injection of the radionuclide allows the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
• The test is not specific and does not indicate the exact pathological condition causing the bleeding, and may miss small sites of bleeding (less than 0.5 mL/min) caused by diverticular disease or angiodysplasia.
• Physiologically unstable patients may be unable to be scanned over long periods or may need to go to surgery before the procedure is complete.
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure evaluates GI bleeding.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- Obtain a history of the patient’s GI system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects.
- Inform the patient that the procedure is performed in a nuclear medicine department by a HCP specializing in this procedure, with support staff, and takes approximately 60 min to complete, with additional images taken periodically over 24 hr.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives. Usually normal saline is infused.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
There are no food or fluid restrictions, unless by medical direction. Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Record baseline vital signs and assess neurological status. Protocols may vary from facility to facility.
- Have emergency equipment readily available.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer a sedative to a child or to an uncooperative adult, as ordered.
- Establish IV fluid line for the injection of emergency drugs, radionuclide, and sedatives.
- Place the patient in a supine position on a flat table with foam wedges to help maintain position and immobilization.
- The radionuclide is administered IV and images are recorded immediately and every 5 min over a period of 60 min in various positions.
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Advise the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Compare with baseline values. Protocols may vary from facility to facility.
- No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- Instruct the patient to resume usual diet, fluids, medication, and activity, as directed by the HCP.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the injection site. Observe for bleeding, hematoma formation, and inflammation.
- If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- Instruct the patient to immediately flush the toilet, and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- Nutritional considerations: A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes. High fat consumption increases the amount of bile acids in the colon and should be avoided.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Plasma (1 mL) collected in chilled, lavender-top (EDTA) tube. Specimen should be transported tightly capped and in an ice slurry.

**REFERENCE VALUE:** (Method: Radioimmunoassay)

**DESCRIPTION:** Glucagon is a hormone secreted by the alpha cells of the islets of Langerhans in the pancreas in response to hypoglycemia. This hormone acts primarily on the liver to promote glucose production from glycogen stores and to control glycogen storage. Glucagon also produces glucose from the oxidation of fatty acids like triglycerides to basic glycerol components. The coordinated release of insulin, glucagon, and somatostatin ensures an adequate fuel supply while maintaining stable blood glucose. Patients with glucagonoma have values greater than 500 ng/L. Values greater than 1000 ng/L are diagnostic for this condition. Glucagonoma causes three different syndromes:

- **Syndrome 1:** A characteristic skin rash, diabetes or impaired glucose tolerance, weight loss, anemia, and venous thrombosis
- **Syndrome 2:** Severe diabetes
- **Syndrome 3:** Multiple endocrine neoplasia

A dramatic increase in glucagon occurring soon after renal
**INDICATIONS:**
- Assist in confirming glucagon deficiency
- Assist in the diagnosis of suspected glucagonoma (alpha islet-cell neoplastic tumor)
- Assist in the diagnosis of suspected renal failure or renal transplant rejection

**RESULT:**

*Increased in:*
Glucagon is produced in the pancreas and excreted by the kidneys; conditions that affect the pancreas and cause cellular destruction or conditions that impair the ability of the kidneys to remove glucagon from circulation will result in elevated glucagon levels.
- Acromegaly *(Growth hormone stimulates production of glucagon)*
- Acute pancreatitis
- Burns *(Stress-induced release of catecholamines stimulates glucagon production)*
- Cirrhosis *(Pathophysiology is not well established)*
- Cushing's syndrome *(Overproduction of cortisol stimulates glucagon production)*
- Diabetes (uncontrolled) *(Pathophysiology is not well established)*
- Glucagonoma
- Hyperlipoproteinemia *(Pathophysiology is not well established)*
- Hypoglycemia *(Produced in response to decreased glucose level)*
- Infection *(Related to feedback loop in response to stress)*
- Kidney transplant rejection
- Pheochromocytoma *(Excessive production of catecholamines stimulates increased glucagon levels)*
- Renal failure
- Stress *(Catecholamines released during stressful periods stimulate production of glucagon)*
- Trauma *(Stress-induced release of catecholamines stimulates glucagon production)*

*Decreased in:*
Related to decreased pancreatic function.
- Chronic pancreatitis
- Cystic fibrosis
- Postpancreatectomy period

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase glucagon levels include amino acids (e.g., arginine), cholecystokinin, danazol, gastrin, glucocorticoids, insulin, and nifedipine.
- Drugs that may decrease glucagon levels include atenolol, pindolol, propranolol, secretin, and verapamil.
- Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when radioimmunoassay is the test method.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of glucagonoma.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to fast for at least 12 hr before specimen collection for baseline values. Diabetic patients should be in good glycemic control before testing.
- Prepare an ice slurry in a cup or plastic bag to have ready for immediate transport of the specimen to the laboratory. Prechill the lavender-top tube in the ice slurry.

INTRATEST:
- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 12 hr prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the

patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a chilled tube. The sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume usual diet, as directed by the HCP.
- Nutritional considerations: Instruct the diabetic patient, as appropriate, in nutritional management of the disease. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. There is no “diabetic diet”; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association. The nutritional needs of each diabetic patient must be determined individually with the appropriate health care professionals, particularly professionals trained in nutrition.
- Increased glucagon levels may be associated with diabetes. Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical
implications of the test results, as appropriate. Emphasize, as appropriate, that good glycemic control delays the onset and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Diabetes Association (www.diabetes.org).

- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include angiography adrenal, catecholamines, cholangiopancreatography endoscopic retrograde, CT cardiac scoring, CT pancreas, CT renal, C peptide, gastric emptying scan, glucose, GTT, glycated hemoglobin, GH, HVA, insulin, insulin antibodies, MRI pancreas, metanephrines, microalbumin, peritoneal fluid analysis, and US pancreas.
- Refer to the Endocrine System table at the end of the book for related tests by body system.

ADA-recommended treatment goal for FBG is less than 120 mg/dL.

Access additional resources at davisplus.fadavis.com
DESCRIPTION: Glucose, a simple six-carbon sugar (monosaccharide), enters the diet as part of the sugars sucrose, lactose, and maltose and as the major constituent of the complex polysaccharide called dietary starch. The body acquires most of its energy from the oxidative metabolism of glucose. Excess glucose is stored in the liver or in muscle tissue as glycogen.

Diabetes is a group of diseases characterized by hyperglycemia or elevated glucose levels. Hyperglycemia results from a defect in insulin secretion (type 1 diabetes), a defect in insulin action, or a combination of defects in secretion and action (type 2 diabetes). The chronic hyperglycemia of diabetes may result over time in damage, dysfunction, and eventually failure of the eyes, kidneys, nerves, heart, and blood vessels. The American Diabetes Association’s criteria for diagnosing diabetes include any combination of the following findings or confirmation of any of the individual findings by repetition on a subsequent day:

- Symptoms of diabetes (e.g., polyuria, polydipsia, unexplained weight loss) in addition to a random glucose level greater than 200 mg/dL
- Fasting blood glucose greater than 126 mg/dL, after a minimum of an 8-hr fast
- Glucose level greater than 200 mg/dL 2 hr after glucose challenge with standardized 75-mg load

RESULT:

Increased in:
- Acromegaly, gigantism (GH stimulates the release of glucagon, which in turn increases glucose levels)
- Acute stress reaction (Hyperglycemia is stimulated by the release of catecholamines and glucagon)
- Cerebrovascular accident (Possibly related to stress)
- Cushing’s syndrome (Related to elevated cortisol)
- Diabetes (Glucose intolerance and elevated glucose levels define diabetes)
- Glucagonoma (Glucagon releases stored glucose; glucagon-secreting tumors will increase glucose levels)
- Hemochromatosis (Related to iron deposition in the pancreas; subsequent damage to pancreatic tissue releases cell contents including glucagon, resulting in hyperglycemia)
- Liver disease (severe) (Damaged liver tissue releases cell contents into circulation including stored glucose)
- Myocardial infarction (Related to stress and/or pre-existing diabetes)
- Pancreatic adenoma (Damage to pancreatic tissue releases cell contents including glucagon, resulting in hyperglycemia)
- Pancreatitis (acute and chronic) (Damage to pancreatic tissue releases cell contents including glucagon, resulting in hyperglycemia)
- Pancreatitis due to mumps (Damage to pancreatic tissue releases cell contents including glucagon, resulting in hyperglycemia)
- Pheochromocytoma (Related to increased catecholamines, which increase glucagon; glucagon increases glucose levels)

INDICATIONS:
- Assist in the diagnosis of insulinoma
- Determine insulin requirements
- Evaluate disorders of carbohydrate metabolism
- Identify hypoglycemia
- Screen for diabetes
• Renal disease (severe) *(Glucagon is degraded by the kidneys; when damaged kidneys cannot metabolize glucagon, glucagon levels in blood rise and result in hyperglycemia)*
• Shock, trauma *(Hyperglycemia is stimulated by the release of catecholamines and glucagon)*
• Somatostatinoma *(Somatostatin-producing tumor of pancreatic delta cells, associated with diabetes)*
• Strenuous exercise *(Hyperglycemia is stimulated by the release of catecholamines and glucagon)*
• Syndrome X (metabolic syndrome) *(Related to the development of diabetes)*
• Thyrotoxicosis *(Related to loss of kidney function)*
• Vitamin B₁ deficiency *(Thiamine is involved in the metabolism of glucose; deficiency results in accumulation of glucose)*

**Decreased in:**
• Acute alcohol ingestion *(Most glucose metabolism occurs in the liver; alcohol inhibits the liver from making glucose)*
• Addison’s disease *(Cortisol affects glucose levels; insufficient levels of cortisol result in diminished glucose levels)*
• Ectopic insulin production from tumors (adrenal carcinoma, carcinoma of the stomach, fibrosarcoma)
• Excess insulin by injection
• Galactosemia *(Inherited enzyme disorder that results in accumulation of galactose in excessive proportion to glucose levels)*
• Glucagon deficiency *(Glucagon controls glucose levels; hypoglycemia occurs in the absence of glucagon)*
• Glycogen storage diseases *(Deficiencies in enzymes involved in conversion of glycogen to glucose)*
• Hereditary fructose intolerance *(Inherited disorder of fructose metabolism; phosphates needed for intermediate steps in gluconeogenesis are trapped from further action by the enzyme deficiency responsible for fructose metabolism)*
• Hypopituitarism *(Decreased levels of hormones such as ACTH and GH result in decreased glucose levels)*
• Hypothyroidism *(Thyroid hormones affect glucose levels; decreased thyroid hormone levels result in decreased glucose levels)*
• Insulinoma *(The function of insulin is to decrease glucose levels)*
• Malabsorption syndromes *(Insufficient absorption of carbohydrates)*
• Maple syrup urine disease *(Inborn error of amino acid metabolism; accumulation of leucine is believed to inhibit the rate of gluconeogenesis, independently of insulin, and thereby diminish release of hepatic glucose stores)*
• Poisoning resulting in severe liver disease *(Decreased liver function correlates with decreased glucose metabolism)*
• Postgastrectomy *(Insufficient intake of carbohydrates)*
• Starvation *(Insufficient intake of carbohydrates)*
• von Gierke disease *(Most common glycogen storage disease; G6PD deficiency)*

**CRITICAL VALUES:**

- Less than 40 mg/dL
- Greater than 400 mg/dL

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms.
Glucose monitoring is an important measure in achieving tight glycemic control. The enzymatic GDH-PQQ test method may produce falsely elevated results in patients who are receiving products that contain other sugars (e.g., oral xylose, parenterals containing maltose or galactose, and peritoneal dialysis solutions that contain icodextrin). The GDH-NAD, glucose oxidase, and glucose hexokinase methods are capable of distinguishing between glucose and other sugars.

Symptoms of decreased glucose levels include headache, confusion, hunger, irritability, nervousness, restlessness, sweating, and weakness. Possible interventions include oral or IV administration of glucose, IV or intramuscular injection of glucagon, and continuous glucose monitoring.

Symptoms of elevated glucose levels include abdominal pain, fatigue, muscle cramps, nausea, vomiting, polyuria, and thirst. Possible interventions include subcutaneous or IV injection of insulin with continuous glucose monitoring.

**INTERFERING FACTORS:**

- Drugs that may increase glucose levels include acetazolamide, alanine, albuterol, anesthetic agents, antipyrine, atenolol, betamethasone, cefotaxime, chlorpromazine, chlorprothixene, clonidine, clorexolone, corticotropin, cortisone, cyclic AMP, cyclopropane, dexamethasone, dextroamphetamine, diapamide, epinephrine, enfurane, ethacrynic acid, ether, fluoxetine, furosemide, glucagon, glucocorticoids, homoharringtonine, hydrochlorothiazide, hydroxydione, isoniazid, maltose, meperidine, meprednisone, methylcloothiaze, metolazone, nacian, nifedipine, normpipritpyline, octreotide, oral contraceptives, oxyphenbutazone, pancreozymin, phenelzine, phenylbutazone, piperacetazine, polythiazide, prednisone, quinethazone, reserpine, rifampin, ritodrine, salbutamol, secretin, somatostatin, thiazides, thyroid hormone, and triamcinolone.

- Drugs that may decrease glucose levels include acarbose, acetylsalicylic acid, acipimox, alanine, allopurinol, antimony compounds, arsenicals, ascorbic acid, benzene, buformin, cannabis, captopril, carbutamide, chloroform, clofibrate, dexfenfluramine, enalapril, enprostil, erythromycin, fenfluramine, gemfibrozil, glibornuride, glyburide, guanethidine, nicertrol, nitrazepam, oral contraceptives, oxandrolone, oxymetholone, phenololamine, phosphorus, promethazine, ramipril, rotenone, sulfonylureas, thiocarlide, tolbutamide, tromethamine, and verapamil.

- Elevated urea levels and uremia can lead to falsely elevated glucose levels.

- Extremely elevated white blood cell counts can lead to falsely decreased glucose values.

- Failure to follow dietary restrictions before the fasting test can lead to falsely elevated glucose values.

- Administration of insulin or oral hypoglycemic agents within 8 hr of a fasting blood glucose can lead to falsely decreased values.

- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is present in the IV solution, falsely increasing the result.

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
Inform the patient that the test is used to assist in the diagnosis of diabetes and to evaluate disorders of carbohydrate metabolism.

Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of medications the patient is taking, including herbs, nutritional supplements, nutraceuticals, insulin, and any other substances used to regulate glucose levels.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

For the fasting glucose test, the patient should fast for at least 12 hr before specimen collection.

The patient should follow the instructions given for 2-hr postprandial glucose test. Some HCP’s may order administration of a standard glucose solution, whereas others may instruct the patient to eat a meal with a known carbohydrate composition.

Ensure that the patient has complied with dietary restrictions and other pretesting preparations; assure that food has been restricted for at least 12 hr prior to the fasting procedure.

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

A report of the results will be sent to the requesting HCP who will discuss the results with the patient.

Instruct the patient to resume usual diet, as directed by the HCP.

Nutritional considerations: Increased glucose levels may be associated with diabetes. Instruct the diabetic patient, as appropriate, in nutritional management of the disease. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. There is no "diabetic diet"; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association. The nutritional needs of each diabetic patient must be determined individually with the appropriate health care professionals, particularly professionals trained in nutrition.

Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).
Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, as appropriate, that good glycemic control delays the onset of and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Diabetes Association (www.diabetes.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ACTH, angiography adrenal, BUN, calcium, catecholamines, cholesterol (HDL, LDL, total), cortisol, C-peptide, CT cardiac scoring, CRP, CK and isoenzymes, creatinine, DHEA, echocardiography, fecal analysis, fecal fat, fluorescein angiography, fructosamine, fundus photography, gastric emptying scan, GTT, glycated hemoglobin A1C, gonioscopy, Holter monitor, HVA, insulin, insulin antibodies, ketones, LDH and isoenzymes, lipoprotein electrophoresis, MRI chest, metanephrines, microalbumin, myoglobin, MI infarct scan, myocardial perfusion heart scan, PET heart, renin, sodium, troponin, and visual fields test.

Refer to the Endocrine System table at the back of the book for related tests by body system.

---

**Glucose-6-Phosphate Dehydrogenase**

**SYNONYM/ACRONYM:** G6PD.

**SPECIMEN:** Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

**REFERENCE VALUE:** (Method: Fluorescent) Qualitative assay—enzyme activity detected; quantitative assay—the following table reflects enzyme activity in units per gram of hemoglobin:

<table>
<thead>
<tr>
<th>Age</th>
<th>Conventional Units</th>
<th>SI Units</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>(Conventional Units × 0.0645)</td>
<td></td>
</tr>
<tr>
<td>Newborn</td>
<td>7.8–14.4 international units/g hemoglobin</td>
<td>0.5–0.93 micro units/mol hemoglobin</td>
</tr>
<tr>
<td>Adult</td>
<td>5.5–9.3 international units/g hemoglobin</td>
<td>0.35–0.60 micro units/mol hemoglobin</td>
</tr>
</tbody>
</table>
**DESCRIPTION:** Glucose-6-phosphate dehydrogenase (G6PD) is a red blood cell enzyme. It is involved in the hexose monophosphate shunt, and its function is to protect hemoglobin from oxidation. G6PD deficiency is an inherited X-linked abnormality; approximately 20% of female carriers are heterozygous. This deficiency results in hemolysis of varying degrees and acuity depending on the severity of the abnormality. There are three G6PD variants of high frequency in different ethnic groups. G6PD A– is more common in African-Americans (10% of males). G6PD Mediterranean is especially common in Iraqis, Kurds, Sephardic Jews, and Lebanese and less common in Greeks, Italians, Turks, North Africans, Spaniards, Portuguese, and Ashkenazi Jews. G6PD Mahidol is common in Southeast Asians (22% of males).

**INDICATIONS:**
- Assist in identifying the cause of hemolytic anemia resulting from drug sensitivity, metabolic disorder, or infection
- Assist in identifying the cause of hemolytic anemia resulting from enzyme deficiency

**RESULT:**

**Increased in:**
- Hepatic coma
- Hyperthyroidism (Possible response to increased basal metabolic rate and role of G6PD in glucose metabolism)
- Idiopathic thrombocytopenic purpura
- Myocardial infarction

*(Medications given, e.g., salicylates, may aggravate or stimulate a hemolytic crisis in G6PD-deficient patients)*
- Pernicious anemia
- Viral hepatitis

**Decreased in:**
- Congenital nonspherocytic anemia
- G6PD deficiency
- Nonimmunological hemolytic disease of the newborn

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Sulfates may decrease G6PD levels.
- G6PD levels are increased in reticulocytes; the test results may be falsely positive when a patient is in a period of acute hemolysis. G6PD levels can also be affected by the presence of large numbers of platelets and white blood cells, which also contain significant amounts of the enzyme.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to identify an enzyme deficiency that can result in red blood cell hemolysis.
- Obtain a history of the patient’s complaints, including a list of known
allergens, especially allergies or sensitivities to latex.

- Obtain a history of the patient’s hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- **Nutritional considerations:** Educate the patient with G6PD deficiency, as appropriate, to avoid certain foods, vitamins, and drugs that may precipitate an acute episode of intravascular hemolysis, including fava beans, ascorbic acid (large doses), acetanilid, antimalarials, furazolidone, isobutyl nitrate, methylene blue, nalidixic acid, naphthalene, niridazole, nitrofurantoin, phenazopyridine, phenylhydrazine, primaquine, sulfacetamide, sulfamethoxazole, sulfanilamide, sulfapyridine, thiazolesulfone, toluidine blue, trinitrotdoluene, and urate oxidase.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include biopsy bone marrow, bilirubin, complete blood count, complete blood count, RBC morphology (including examination of peripheral smear for the presence of Heinz bodies), direct antiglobulin test, folate, Ham’s test, haptoglobin, hemosiderin, osmotic fragility, reticulocyte count, UA, and vitamin B₁₂.
- Refer to the Hematopoietic System table at the back of the book for related tests by body system.
**SYNONYM/ACRONYM:** Standard oral tolerance test, standard gestational screen, standard gestational tolerance test, GTT.

**SPECIMEN:** Plasma (1 mL) collected in gray-top (sodium fluoride) tube. Serum (1 mL) collected in a red- or tiger-top tube or plasma collected in a green-top (heparin) tube is also acceptable. It is important to use the same type of collection container throughout the entire test.

**REFERENCE VALUE:** (Method: Spectrophotometry)

**Glucose Tolerance Tests**

**DESCRIPTION:** The glucose tolerance test (GTT) measures glucose levels after administration of an oral or IV carbohydrate challenge. Patients with diabetes are unable to metabolize glucose at a normal rate. The oral GTT is used for individuals who are able to eat and who are not known to have problems with gastrointestinal malabsorption. The IV GTT is used for individuals who are unable to tolerate oral glucose.

Diabetes is a group of diseases characterized by hyperglycemia or elevated glucose levels. Hyperglycemia results from a defect in insulin secretion (type 1 diabetes), a defect in insulin action, or a combination of dysfunction secretion and action (type 2 diabetes). The chronic hyperglycemia of diabetes over time results in damage, dysfunction, and eventually failure of the eyes, kidneys, nerves, heart, and blood vessels. The American Diabetes Association’s criteria for diagnosing diabetes include any combination of the following findings or confirmation of any

Plasma glucose values are reported to be 10%–20% higher than serum values.
of the individual findings by repetition on a subsequent day:
  • Symptoms of diabetes (e.g., polyuria, polydipsia, and unexplained weight loss) in addition to a random glucose level greater than 200 mg/dL.
  • Fasting blood glucose greater than 126 mg/dL, after a minimum of an 8-hr fast.
  • Glucose level greater than 200 mg/dL 2 hr after glucose challenge with standardized 75-mg load.

**INDICATIONS:**
  • Evaluate abnormal fasting or postprandial blood glucose levels that do not clearly indicate diabetes.
  • Evaluate glucose metabolism in women of childbearing age, especially women who are pregnant and have (1) a history of previous fetal loss or birth of infants weighing 9 pounds or more, and/or (2) a family history of diabetes.
  • Identify abnormal renal tubular function if glycosuria occurs without hyperglycemia.
  • Identify impaired glucose metabolism without overt diabetes.
  • Support the diagnosis of hyperthyroidism and alcoholic liver disease, which are characterized by a sharp rise in blood glucose followed by a decline to subnormal levels.

**RESULT:**

**Tolerance increased in:**
  • Decreased absorption of glucose: Adrenal insufficiency (Addison’s disease), hypopituitarism
  • Hypothyroidism
  • Intestinal diseases, such as celiac disease and tropical sprue
  • Whipple’s disease
  • Increased insulin secretion: Pancreatic islet cell tumor

**Tolerance impaired in:**
  • Increased absorption of glucose: Excessive intake of glucose
  • Gastrectomy
  • Gastroenterostomy
  • Hyperthyroidism
  • Vagotomy
  • Decreased usage of glucose: Central nervous system lesions
  • Cushing’s syndrome
  • Diabetes
  • Hemochromatosis
  • Hyperlipidemia
  • Decreased glycogenesis: Hyperthyroidism
  • Infections
  • Liver disease (severe)
  • Pheochromocytoma
  • Pregnancy
  • Stress
  • von Gierke disease

**CRITICAL VALUES:**
Less than 40 mg/dL
Greater than 400 mg/dL
Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms.

Symptoms of decreased glucose levels include headache, confusion, hunger, irritability, nervousness, restlessness, sweating, and weakness. Possible interventions include oral or IV administration of glucose, IV or intramuscular injection of glucagon, and continuous glucose monitoring.

Symptoms of elevated glucose levels include abdominal pain, fatigue, muscle cramps, nausea, vomiting, polyuria, and thirst. Possible interventions include subcutaneous or IV injection of insulin with continuous glucose monitoring.

**INTERFERING FACTORS:**
  • Drugs and substances that may increase GTT values include acetylsalicylic acid, atenolol, bendroflumethiazide, caffeine, clofibrate, fenfluramine, fluoxymesterone,
GLUCOSE TOLERANCE TESTS

glyburide, guanethidine, lisinopril, methandrostanolone, metoprolol, nandrolone, niceritrol, nifedipine, nitrendipine, norethisterone, phenformin, phenobarbital, prazosin, and terazosin.

- Drugs and substances that may decrease GTT values include acebutolol, beclomethasone, bendroflumethiazide, betamethasone, calcitonin, catecholamines, chlorothiazide, chlorpromazine, chlorthalidone, cimetidine, corticotropin, cortisone, danazol, deflazacort, dexamethasone, diapamide, diethylstilbestrol, ethacryninc acid, fluordrocortisone, furosemide, glucagon, glucocorticosteroids, heroin, hydrochlorothiazide, mephenytoin, mestranol, methadone, methandrostanolone, methylprednisolone, muzolimine, niacin, nifedipine, norethindrone, norethynodrel, oral contraceptives, paramethasone, perphenazine, phenolphthalein, phenothiazine, phenytoin, pindolol, prednisolone, prednisone, propranolol, quinethazone, thiazides, triamcinolone, triamterene, and verapamil.

- The test should be performed on ambulatory patients. Impaired physical activity can lead to falsely increased values.
- Excessive physical activity before or during the test can lead to falsely decreased values.
- Failure of the patient to ingest a diet with sufficient carbohydrate content (e.g., 150 g/day) for at least 3 days before the test can result in falsely decreased values.
- The patient may have difficulty drinking the extremely sweet glucose beverage and become nauseous. Vomiting during the course of the test will cause the test to be canceled.
- Smoking before or during the test can lead to falsely increased values.
- The patient should not be under recent or current physiological stress during the test. If the patient has had recent surgery (less than 2 wk previously), an infectious disease, or a major illness (e.g., myocardial infarction), the test should be delayed or rescheduled.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of diabetes.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Inform the patient that multiple specimens may be required. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- The patient should fast for at least 8 to 12 hr before the standard oral and standard gestational GTTs.
- There are no fluid or medication restrictions, unless by medical direction prior to the gestational screen.

INTRATEST:

- Ensure that the patient has complied with dietary and activity restrictions as well as other pretesting preparations; assure that food has been restricted.
for at least 8 to 12 hr prior to the procedure.
If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
Promptly transport the specimen to the laboratory for processing and analysis. Do not wait until all specimens have been collected to transport.

**Standard Oral GTT:**
The standard oral GTT takes 2 hr. A fasting blood glucose is determined before administration of an oral glucose load. If the fasting blood glucose is less than 126 mg/dL, the patient is given an oral glucose load.
An oral glucose load should not be administered before the value of the fasting specimen has been received. If the fasting blood glucose is greater than 126 mg/dL, the standard glucose load is not administered and the test is canceled. The laboratory will follow its protocol as far as notifying the patient of his or her glucose level and the reason why the test was canceled. The requesting HCP will then be issued a report indicating the glucose level and the cancellation of the test. A fasting glucose greater than 126 mg/dL indicates diabetes; therefore, the glucola would never be administered before allowing the requesting HCP to evaluate the clinical situation.
Adults receive 75 g and children receive 1.75 g/kg ideal weight, not to exceed 75 g. The glucose load should be consumed within 5 min, and time 0 begins as soon as the patient begins to ingest the glucose load. A second specimen is collected at 2 hr, concluding the test. The test is discontinued if the patient vomits before the second specimen has been collected.

**Standard Gestational Screen:**
The standard gestational screen is performed on pregnant women. If results from the screen are abnormal, a full gestational GTT is performed. The gestational screen does not require a fast. The patient is given a 50-g oral glucose load. The glucose load should be consumed within 5 min, and time 0 begins as soon as the patient begins to ingest the glucose load. A specimen is collected 1 hr after ingestion. The test is discontinued if the patient vomits before the 1-hr specimen has been collected.

**Standard Gestational GTT:**
The standard gestational GTT takes 3 hr. A fasting blood glucose is determined before administration of a 100-g oral glucose load. If the fasting blood glucose is less than 126 mg/dL, the patient is given an oral glucose load.
An oral glucose load should not be administered before the value of the fasting specimen has been received. If the fasting blood glucose is greater than 126 mg/dL, the glucola is not administered and the test is canceled (see previous explanation).
The glucose load should be consumed within 5 min, and time 0 begins as soon as the patient begins to ingest the glucose load. Subsequent specimens are collected at 1, 2, and 3 hr, concluding the test. The test is discontinued if the patient vomits before all specimens have been collected.

**POST-TEST:**
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
Instruct the patient to resume usual diet and activity, as directed by the HCP.
**Nutritional considerations:** Increased glucose levels may be associated with diabetes. Instruct the diabetic patient, as appropriate, in nutritional management of the disease. Patients who adhere to dietary recommendations report a better general feeling of
health, better weight management, greater control of glucose and lipid values, and improved use of insulin. There is no “diabetic diet”; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association. The nutritional needs of each diabetic patient need to be determined individually with the appropriate health care professionals, particularly professionals trained in nutrition.

Impaired glucose tolerance may be associated with diabetes. Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).

Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, as appropriate, that good glycemic control delays the onset of and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Diabetes Association (www.diabetes.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ACTH, ALP, antibodies gliadin, angiography adrenal, biopsy intestinal, biopsy thyroid, BUN, C-peptide, capsule endoscopy, catecholamines, cholesterol (total and HDL), cortisol, creatinine, DHEAS, fecal fat, folate, fructosamine, gastric acid stimulation, gastrin stimulation, glucagon, glucose, glycated hemoglobin, 5-HIAA, insulin, insulin antibodies, ketones, metanephrines, microalbumin, oxalate, RAIU, thyroid scan, TSH, thyroxine, triglycerides, and VMA.

- Refer to the Endocrine System table at the back of the book for related tests by body system.

---

**γ-Glutamyltransferase**

**SYNONYM/ACRONYM:** Serum γ-glutamyltransferase, γ-glutamyl transpeptidase, GGT, SGGT.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

**REFERENCE VALUE:** (Method: Spectrophotometry)

Access additional resources at davisplus.fadavis.com
**DESCRIPTION:** Glutamyltransferase (GGT) assists with the reabsorption of amino acids and peptides from the glomerular filtrate and intestinal lumen. Hepatobiliary, renal tubular, and pancreatic tissues contain large amounts of GGT. Other sources include the prostate gland, brain, and heart. GGT is elevated in all types of liver disease and is more responsive to biliary obstruction, cholangitis, or cholecystitis than any of the other enzymes used as markers for liver disease.

**INDICATIONS:**
- Assist in the diagnosis of obstructive jaundice in neonates
- Detect the presence of liver disease
- Evaluate and monitor patients with known or suspected alcohol abuse (levels rise after ingestion of small amounts of alcohol)

**RESULT:**

*Increased in:*

GGT is released from any damaged cell in which it is stored so conditions that affect the liver, kidneys, or pancreas and cause cellular destruction demonstrate elevated GGT levels.

- Cirrhosis
- Diabetes with hypertension
- Hepatitis
- Hepatobiliary tract disorders
- Hepatocellular carcinoma
- Hyperthyroidism (There is a strong association with concurrent liver abnormalities)
- Infectious mononucleosis
- Obstructive liver disease
- Pancreatitis
- Renal transplantation
- Significant alcohol ingestion

*Decreased in:*
- Hypothyroidism (Related to decreased enzyme production by the liver)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase GGT levels include acetaminophen, aminoglutethimide, anticonvulsants, barbiturates, captopril, clotiazepam, disulfiram, methyl-dopa, oral contraceptives, phenothiazines, rifampin, and streptokinase.
- Drugs that may decrease GGT levels include bezafibrate, cefotaxime, clofibrate, fenofibrate, and ursodiol.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess liver function.
- Obtain a history of the patient’s complaints, including a list of known allergies, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hepatobiliary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a history of IV drug use, alcohol use, high-risk sexual activity, and occupational exposure.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that...
A high-protein, moderate-fat diet with a high fluid intake is often recommended for patients with hepatitis. Treatment of cirrhosis is different because a low-protein diet may be in order if the patient’s liver has lost the ability to process the end products of protein metabolism. A diet of soft foods also may be required if esophageal varices have developed. Ammonia levels may be used to determine whether protein should be added to or reduced from the diet. The patient should be encouraged to eat simple carbohydrates and emulsified fats (as in homogenized milk or eggs), as opposed to complex carbohydrates (e.g., starch, fiber, and glycogen [animal carbohydrates]) and complex fats, which require additional bile to emulsify them so that they can be used. The cirrhotic patient should also be carefully observed for the development of ascites, in which case fluid and electrolyte balance requires strict attention. The alcoholic patient should be encouraged to avoid alcohol and to seek appropriate counseling for substance abuse.

Recognize anxiety related to test results, and be supportive of impaired activity related to lack of neuromuscular control, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Nutritional considerations: Increased GGT levels may be associated with liver disease. Dietary recommendations may be indicated and vary depending on the condition and its severity. Currently, there are no specific medications that can be given to cure hepatitis, but elimination of alcohol ingestion and a diet optimized for convalescence are commonly included in the treatment plan. A high-calorie, high-protein, moderate-fat diet with a high fluid intake is often recommended for patients with hepatitis. Treatment of cirrhosis is different because a low-protein diet may be in order if the patient’s liver has lost the ability to process the end products of protein metabolism. A diet of soft foods also may be required if esophageal varices have developed. Ammonia levels may be used to determine whether protein should be added to or reduced from the diet. The patient should be encouraged to eat simple carbohydrates and emulsified fats (as in homogenized milk or eggs), as opposed to complex carbohydrates (e.g., starch, fiber, and glycogen [animal carbohydrates]) and complex fats, which require additional bile to emulsify them so that they can be used. The cirrhotic patient should also be carefully observed for the development of ascites, in which case fluid and electrolyte balance requires strict attention. The alcoholic patient should be encouraged to avoid alcohol and to seek appropriate counseling for substance abuse.

Recognize anxiety related to test results, and be supportive of impaired activity related to lack of neuromuscular control, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.
Glycated Hemoglobin

SYNONYM/ACRONYM: Hemoglobin A$_{1C}$, A$_{1C}$.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

REFERENCE VALUE: (Method: Chromatography)

<table>
<thead>
<tr>
<th>Test</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total A$_1$</td>
<td>4.0–7.0%</td>
</tr>
<tr>
<td>A$_{1C}$</td>
<td>4.0–5.5%</td>
</tr>
</tbody>
</table>

Values vary widely by method. ADA-recommended treatment goal for hemoglobin A$_{1C}$ is less than 7%.

DESCRIPTION: Glycosylated or glycated hemoglobin is a term used to describe the combination of glucose and hemoglobin into a ketamine; the rate at which this occurs is proportional to glucose concentration. The average life span of a red blood cell (RBC) is approximately 120 days; measurement of glycated hemoglobin is a way to monitor long-term diabetic management. The average plasma glucose can be estimated using the formula:

$$\text{Average plasma glucose (mg/dL)} = \frac{(\text{A$_{1C}$} \times 35.6) - 77.3}{6}$$

For example an A$_{1C}$ value of 6% would reflect an average plasma glucose of 136.3 mg/dL or $[(6 \times 35.6) - 77.3]$.

Diabetes is a group of diseases characterized by hyperglycemia or elevated glucose levels. Hyperglycemia results from a defect in insulin secretion (type 1 diabetes), a defect in insulin action, or a combination of dysfunctional secretion and action (type 2 diabetes). The chronic hyperglycemia of diabetes over time results in damage, dysfunction, and eventually failure of the eyes, kidneys, nerves, heart, and blood vessels. Hemoglobin A$_{1C}$ levels are not age dependent and are not affected by exercise, diabetic medications, or nonfasting state before specimen collection.

INDICATIONS: Assess long-term glucose control in diabetics

RELATED MONOGRAPHS:
- Related tests include ALT, ALP, ammonia, AST, bilirubin, cholangiography, percutaneous transhepatic, electrolytes, HAV antibody, HBV antigen and antibody, HCV antibody, hepatobiliary scan, infectious mono screen, KUB studies, liver and spleen scan, MRI liver, TSH, and US liver.
- Refer to the Hepatobiliary System table at the back of the book for related tests by body system.
RESULT:

**Increased in:**
- Diabetes (poorly controlled or uncontrolled) *(Related to and reflective of elevated glucose levels)*

**Decreased in:**
- Chronic blood loss *(Blood loss decreases concentration of RBC-bound glycated hemoglobin)*
- Chronic renal failure *(Low RBC count associated with this condition reflects corresponding decrease in RBC bound glycated hemoglobin)*
- Conditions that decrease RBC life span *(Low RBC count reflects corresponding decrease in RBC-bound glycated hemoglobin)*
- Hemolytic anemia *(Low RBC count due to hemolysis reflects corresponding decrease in RBC-bound glycated hemoglobin)*
- Pregnancy *(Low RBC associated with pregnancy reflects corresponding decrease in RBC-bound glycated hemoglobin)*

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase glycated hemoglobin A\(_{1C}\) values include hydrochlorothiazide, indapamide, insulin, morphine, propranolol, and sulfonyleurases.
- Drugs that may decrease glycated hemoglobin A\(_{1C}\) values include carbamate, galactose, and metformin.
- Conditions involving abnormal hemoglobins (hemoglobinopathies) affect the reliability of glycated hemoglobin A\(_{1C}\) values, causing (1) falsely increased values, (2) falsely decreased values, or (3) discrepancies in either direction depending on the method.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess long-term glycemic control (past 3 mo).
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally.
and to avoid unnecessary movement.

- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

**Nutritional considerations:** Increased glycated hemoglobin A1C levels may be associated with diabetes. Instruct the diabetic patient, as appropriate, in nutritional management of the disease. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. There is no “diabetic diet”; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association. The nutritional needs of each diabetic patient must be determined individually with the appropriate health care professionals, particularly professionals trained in nutrition.
- Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy.
- Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, as appropriate, that good glycemic control delays the onset of and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Diabetes Association (ADA) (www.diabetes.org). The ADA recommends A1C testing 4 times a yr for insulin-dependent type 1 or type 2 diabetes and twice a yr for non–insulin-dependent type 2 diabetes.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient in the use of FDA approved home test kits, if prescribed. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include C-peptide, cholesterol (total and HDL), CT cardiac scoring, creatinine/eGFR, EMG, ENG, fluorescein angiography, fructosamine, fundus photography, gastric emptying scan, glucagon, glucose, glucose tolerance tests, insulin, insulin antibodies, ketones, microalbumin, plethysmography, slit-lamp biomicroscopy, triglycerides, and visual fields test.
- Refer to the Endocrine System table at the back of the book for related tests by body system.
Gonioscopy

SYNONYM/ACRONYM: N/A.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION: Gonioscopy is a technique used for examination of the anterior chamber structures of the eye, i.e., the trabecular meshwork and the anatomic relationship of the trabecular meshwork to the iris. The trabecular meshwork is the drainage system of the eye, and gonioscopy is performed to determine if it is suspected that the drainage angle may be damaged, blocked, or clogged. Gonioscopy in combination with biomicroscopy is considered to be the most thorough basis to confirm a diagnosis of glaucoma and to differentiate between open-angle and angle-closure glaucoma. The angle structures of the anterior chamber are normally not visible because light entering the eye through the cornea is reflected back into the anterior chamber. Placement of a special contact lens (goniolens) over the cornea allows reflected light to pass back through the cornea and onto a reflective mirror in the contact lens. It is in this way that the angle structures can be visualized. There are two types of gonioscopy; indirect and direct. The more commonly used indirect technique employs a mirrored goniolens and biomicroscope.

Direct gonioscopy is performed with a gonioscope containing a dome-shaped contact lens known as a gonioprism. The gonioprism eliminates internally reflected light, allowing direct visualization of the angle. Interpretation of visual examination is usually documented in a colored hand-drawn diagram. Scheie’s classification is used to standardize definition of angles based on appearance by gonioscopy. Shaffer’s classification is based on the angular width of the angle recess.

INDICATIONS:
- Assessment of peripheral anterior synchiae (PAS)
- Conditions affecting the ciliary body
- Degenerative conditions of the anterior chamber
- Evaluation of glaucoma (confirmation of normal structures and estimation of angle width)
- Growth or tumor in the angle
- Hyperpigmentation
- Post-trauma evaluation for angle recession
- Suspected neovascularization of the angle
- Uveitis
Normal findings in:
- Normal appearance of anterior chamber structures and wide, unblocked, normal angle

Abnormal findings in:
- Corneal endothelial disorders (Fuchs endothelial dystrophy, iridocorneal endothelial syndrome)
- Glaucoma
- Lens disorders (cataract, displaced lens)
- Malignant ocular neoplasm in angle
- Neovascularization in angle
- Ocular hemorrhage
- PAS
- Schwartz syndrome
- Trauma
- Tumors
- Uveitis

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Inability of the patient to cooperate or remain still during the test because of age, significant pain, or mental status may interfere with the test results.

### Scheie’s Classification Based on Visible Angle Structures

<table>
<thead>
<tr>
<th>Classification</th>
<th>Appearance</th>

</tbody>
</table>

**RESULT:**

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient the procedure detects abnormalities in the structures of the anterior chamber of the eye.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; and eye surgery; as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.
- Review the procedure with the patient. Explain that the patient will be requested...
to fixate the eyes during the procedure. Address concerns about pain related to the procedure. Explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Explain to the patient that some discomfort may be experienced after the test when the numbness wears off from anesthetic drops administered prior to the test. Inform the patient that the test is performed by a health care provider (HCP) or optometrist specially trained to perform this procedure and takes about 5 min to complete.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- Seat the patient comfortably. Instill ordered topical anesthetic in each eye, as ordered, and allow time for it to work. Topical anesthetic drops are placed in the eye with the patient looking up and the solution directed at the six o’clock position of the sclera (white of the eye) near the limbus (grey, semi-transparent area of the eyeball where the cornea and sclera meet). Neither the dropper nor the bottle should touch the eyelashes.
- Ask the patient to place the chin in the chin rest and gently press the forehead against the support bar. Ask the patient to open his or her eyes wide and look at desired target. Explain that the HCP or optometrist will place a lens on the eye while a narrow beam of light is focused on the eye.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss or anticipated loss of driving privileges. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include fundus photography, pachymetry, slit-lamp biomicroscopy, and visual field testing.
- Refer to the Ocular System table at the back of the book for related tests by body system.

---

**Gram Stain**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Blood, biopsy specimen, or body fluid as collected for culture.

**REFERENCE VALUE:** N/A.
DESCRIPTION: Gram stain is a technique commonly used to identify bacterial organisms based on their specific staining characteristics. The method involves smearing a small amount of specimen on a slide, and then exposing it to gentian or crystal violet, iodine, alcohol, and safranin O. Gram-positive bacteria retain the gentian or crystal violet and iodine stain complex after a decolorization step and appear purple-blue in color. Gram-negative bacteria do not retain the stain after decolorization but can pick up the pink color of the safranin O counterstain. Gram stain results should be correlated with culture results to interpret the significance of isolated organisms. A sputum Gram stain showing greater than 25 squamous epithelial cells per low-power field, regardless of the number of polymorphonuclear white blood cells, indicates contamination of the specimen with saliva, and the specimen should be rejected for subsequent culture. The occasional presence of bacteria in an unspun urine Gram stain suggests a correlating colony count of 10,000 bacteria/mL. The presence of bacteria in most fields is clinically significant and suggests greater than 100,000 bacteria/mL of urine.

INDICATIONS:
- Provide a rapid determination of the acceptability of the specimen for further analysis
- Provide rapid, presumptive information about the type of potential pathogen present in the specimen (i.e., gram-positive bacteria, gram-negative bacteria, or yeast)

RESULT:

</table>

Note: Treponema species are classified as gram-negative spirochetes, but they are most often visualized using dark-field or silver staining techniques.
CRITICAL VALUES:

- Note and immediately report to the health care provider (HCP) any positive results in blood, cerebrospinal fluid, or any body cavity fluid, along with related symptoms.

INTERFERING FACTORS:

- Very young, very old, or dead cultures may react atypically to the Gram stain technique.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in identifying the presence of pathogenic organisms.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s gastrointestinal, genitourinary, immune, reproductive, and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedure.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that the time it takes to collect a proper specimen varies according to the patient’s level of cooperation as well as the specimen collection site. Address concerns about pain and explain to the patient that there may be some discomfort during the procedure.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.
- Specific collection instructions are found in the associated culture monographs.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Administer antibiotics as ordered, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include amniotic fluid analysis, relevant biopsies, bronchoscopy, cultures bacterial and viral, CSF analysis, complete blood count, pericardial fluid analysis, peritoneal fluid analysis, pleural fluid analysis, synovial fluid analysis, and UA.
- Refer to the Gastrointestinal, Genitourinary, Immune, Reproductive, and Respiratory System tables at the back of the book for related tests by body system.
Group A Streptococcal Screen

SYNONYM/ACRONYM: Strep screen, rapid strep screen, direct strep screen.

SPECIMEN: Throat swab (two swabs should be submitted so that a culture can be performed if the screen is negative).

REFERENCE VALUE: *(Method: Enzyme immunoassay or latex agglutination)*
Negative.

DESCRIPTION: Rheumatic fever is a possible sequela to an untreated streptococcal infection. Early diagnosis and treatment appear to lessen the seriousness of symptoms during the acute phase and overall duration of the infection and sequelae. The onset of strep throat is sudden and includes symptoms such as chills, headache, sore throat, malaise, and exudative gray-white patches on the tonsils or pharynx. The group A streptococcal screen should not be ordered unless the results would be available within 1 to 2 hr of specimen collection to make rapid, effective therapeutic decisions. A positive result can be a reliable basis for the initiation of therapy. A negative result is presumptive for infection and should be backed up by culture results. In general, specimens showing growth of less than 10 colonies on culture yield negative results by the rapid screening method. Evidence of group A streptococci disappears rapidly after the initiation of antibiotic therapy. A nucleic acid probe method has also been developed for rapid detection of group A streptococci.

INDICATIONS: Assist in the rapid determination of the presence of group A streptococci.

RESULT:
Positive findings in:
- Rheumatic fever
- Scarlet fever
- Strep throat
- Streptococcal glomerulonephritis
- Tonsillitis

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Polyester (rayon or dacron) swabs are favored over cotton for best chance of detection. Fatty acids are created on cotton fibers during the sterilization process. Detectable target antigens on the streptococcal cell wall are destroyed without killing the organism when there is contact between the specimen and the fatty acids on the cotton collection swab. False-negative test results can be obtained on specimens collected with cotton tip swabs. Negative strep screens should always be followed with a traditional culture.
- Sensitivity of the method varies from manufacturer to manufacturer.
- Adequate specimen collection in children may be difficult to achieve, which explains the higher percentage of false-negative results in this age group.
NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to detect group A streptococcal infection.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a history of prior antibiotic therapy.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Before specimen collection, verify with the laboratory whether wet or dry swabs are preferred for collection.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the swabbing procedure.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, date, and time of collection. Vigorous swabbing of both tonsillar pillars and the posterior throat enhances the probability of streptococcal antigen detection.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Administer antibiotics as ordered, and emphasize to the patient or caregiver the importance of completing the entire course of antibiotic therapy even if no symptoms are present.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related laboratory tests include analgesic and antipyretic drugs, antibiotic drugs, ASO, chest x-ray, complete blood count, culture (throat, viral), and gram stain.
- Refer to the Immune and Respiratory System tables at the back of the book for related tests by body system.
Growth Hormone, Stimulation and Suppression Tests

SYNONYM/ACRONYM: Somatotropic hormone, somatotropin, GH, hGH.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

Stimulation Tests
- Rise above baseline: Greater than 5 ng/mL (Greater than 5 mcg/L)
- Peak response: Greater than 10 ng/mL (Greater than 10 mcg/L)

Suppression Tests
- 0–2 ng/mL (0–2 mcg/L)

DESCRIPTION: Human growth hormone (GH) is secreted in episodic bursts by the anterior pituitary gland; the highest level is usually secreted during deep sleep. Release of GH is modulated by three hypothalamic factors: GH-releasing hormone, GH-releasing peptide-6, and GH inhibitory hormone (also known as somatostatin). The effects of GH are carried out by insulin-like growth factors, formerly called somatomedins. GH plays an integral role in growth from birth to puberty. GH promotes skeletal growth by stimulating hepatic production of proteins; it also affects lipid and glucose metabolism. Random levels are rarely useful because secretion of GH is episodic and pulsatile. Stimulation tests with arginine, glucagon, insulin, or L-dopa, as well as suppression tests with glucose, provide useful information.

INDICATIONS:
- Assist in the diagnosis of acromegaly in adults
- Assist in establishing a diagnosis of dwarfism or growth retardation in
children with decreased GH levels, indicative of a pituitary cause
• Assist in establishing a diagnosis of gigantism in children with GH increased levels, indicative of a pituitary cause
• Detect suspected disorder associated with decreased GH
• Monitor response to treatment of growth retardation

RESULT:

Increased in:
Production of GH is modulated by numerous factors including stress, exercise, sleep, nutrition, and response to circulating levels of GH.
• Acromegaly
• Anorexia nervosa
• Cirrhosis
• Diabetes (uncontrolled)
• Ectopic GH secretion (neoplasms of stomach, lung)
• Exercise
• Gigantism (pituitary)
• Hyperpituitarism
• Laron dwarfism
• Malnutrition
• Renal failure
• Stress

Decreased in:
• Adrenocortical hyperfunction (Inhibits secretion of GH)
• Dwarfism (pituitary) (Related to GH deficiency)
• Hypopituitarism (Related to lack of production)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may increase GH levels include alanine, anabolic steroids, angiotensin II, apomorphine, arginine, clonidine, corticotropin, cyclic AMP, desipramine, dexamethasone, dopamine, fenfluramine, galanin, glucagon, GH-releasing hormone, hydrazine, levodopa, methamphetamine, methyldopa, metoclopramide, midazolam, niacin, oral contraceptives, phenytoin, propranolol, and vasopressin.
• Drugs that may decrease GH levels include corticosteroids, corticotropin, hydrocortisone, octreotide, and pirenzepine.
• Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when radioimmunoassay is the test method.
• Failure to follow dietary and activity restrictions before the procedure may cause the procedure to be canceled or repeated.
Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

The patient should fast and avoid strenuous exercise for 12 hr before specimen collection. Protocols may vary from facility to facility.

INTRATEST:

Ensure that the patient has complied with dietary and activity restrictions; assure that food and strenuous activity have been restricted for at least 12 hr prior to the procedure.

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. Test samples may be requested at baseline and 10-, 20-, 30-, 45-, and 60-min intervals after stimulation and at baseline and 30-, 60-, 90-, and 120-min intervals after suppression.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage. Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

A related test is ACTH.

Refer to the Endocrine System table at the back of the book for related tests by body system.
Ham’s Test for Paroxysmal Nocturnal Hemoglobinuria

**SYNONYM/ACRONYM:** Acid hemolysis test for PNH.

**SPECIMEN:** Whole blood (5 mL) collected in lavender-top (EDTA) tube and serum (3 mL) collected in red-top tube.

**REFERENCE VALUE:** (Method: Acidified hemolysis) No hemolysis seen.

**RESULT:**

**Increased in:**
- Congenital dyserythropoietic anemia, type II
- PNH

**CRITICAL VALUES:** N/A

**DESCRIPTION:** Haptoglobin is an α₂-globulin produced in the liver. It binds with the free hemoglobin released when red blood cells (RBCs) are lysed. If left unchecked, free hemoglobin in the plasma can cause renal damage; haptoglobin prevents it from accumulating. In conditions such as hemolytic anemia, so many hemolyzed RBCs are available for binding that the liver cannot compensate by producing additional haptoglobin fast enough, resulting in low serum levels.

**INDICATIONS:**
- Assist in the investigation of suspected transfusion reaction
- Evaluate known or suspected chronic liver disease, as indicated by decreased levels of haptoglobin
• Evaluate known or suspected disorders characterized by excessive RBC hemolysis, as indicated by decreased levels of haptoglobin
• Evaluate known or suspected disorders involving a diffuse inflammatory process or tissue destruction, as indicated by elevated levels of haptoglobin

RESULT:

**Increased in:**
- Biliary obstruction
- Disorders involving tissue destruction, such as cancers, burns, and acute myocardial infarction
- Infection or inflammatory diseases, such as ulcerative colitis, arthritis, and pyelonephritis
- Neoplasms
- Steroid therapy

**Decreased in:**
- Autoimmune hemolysis
- Hemolysis due to drug reaction
- Hemolysis due to mechanical destruction (e.g., artificial heart valves, contact sports, subacute bacterial endocarditis)
- Hemolysis due to RBC membrane or metabolic defects
- Hemolysis due to transfusion reaction
- Hypersplenism
- Ineffective hematopoiesis due to conditions such as folate deficiency or hemoglobinopathies
- Liver disease

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase haptoglobin levels include anabolic steroids, danazol, ethylestrenol, fluoxymesterone, methandrostenolone, norethandrolone, oxandrolone, oxymetholone, and stanozolol.
- Drugs that may decrease haptoglobin levels include acetanilid, aminosalicylic acid, chlorpromazine, dapsone, dextran, diphenhydramine, furadaltone, furazolidone, isoniazid, nitrofurantoin, norethindrone, oral contraceptives, quinidine, resorcinol, stibophen, tamoxifen, thiazolsulfone, and tripelennamine.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is primarily used to investigate hemolytic states.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic, hepatobiliary, and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate
Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ALT, AST, bilirubin, blood group and type, complete blood count, complete blood count, RBC count, complete blood count, RBC indices, complete blood count, RBC morphology, Coombs’ antiglobulin, folate, G6PD, GGT, Ham’s test, hepatobiliary scan, and osmotic fragility.
- Refer to the Hematopoietic, Hepatobiliary, and Immune System tables at the back of the book for related tests by body system.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to immediately report symptoms of hemolysis, including chills, fever, flushing, back pain, and fast heartbeat, to the HCP.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.

**SYNONYM/ACRONYM:** *H. pylori.*

**SPECIMEN:** Serum (1 mL) collected in a plain red-top tube.

**REFERENCE VALUE:** (Method: Enzyme-linked immunosorbent assay [ELISA]) Negative.

**DESCRIPTION:** There is a strong association between *Helicobacter pylori* infection and gastric cancer, duodenal and gastric ulcer, and chronic gastritis. Immunoglobulin G (IgG) antibodies can be detected for up to 1 yr after treatment. The presence of *H. pylori* can also be demonstrated by a positive urea breathe test, positive stool culture, or positive endoscopic biopsy. Patients with symptoms and evidence of *H. pylori* infection are considered to be infected with the organism; patients who demonstrate evidence of *H. pylori* but are without symptoms are said to be colonized.

---

**Helicobacter Pylori Antibody**

**SYNONYM/ACRONYM:** *H. pylori.*

**SPECIMEN:** Serum (1 mL) collected in a plain red-top tube.

**REFERENCE VALUE:** (Method: Enzyme-linked immunosorbent assay [ELISA]) Negative.

**DESCRIPTION:** There is a strong association between *Helicobacter pylori* infection and gastric cancer, duodenal and gastric ulcer, and chronic gastritis. Immunoglobulin G (IgG) antibodies can be detected for up to 1 yr after treatment. The presence of *H. pylori* can also be demonstrated by a positive urea breathe test, positive stool culture, or positive endoscopic biopsy. Patients with symptoms and evidence of *H. pylori* infection are considered to be infected with the organism; patients who demonstrate evidence of *H. pylori* but are without symptoms are said to be colonized.
INDICATIONS:
- Assist in differentiating between H. pylori infection and NSAID use as the cause of gastritis or peptic or duodenal ulcer
- Assist in establishing a diagnosis of gastritis, gastric carcinoma, or peptic or duodenal ulcer

RESULT:

Positive findings in:
- H. pylori infection
- H. pylori colonization

Negative findings in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of H. pylori infection in patients with duodenal and gastric disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s gastrointestinal and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
- If the patient has a history of an allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that a positive test result constitutes an independent risk factor for gastric cancer. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include capsule endoscopy, EGD, gastric acid stimulation, gastric emptying scan, gastrin, and upper GI series.
- Refer to the Gastrointestinal and Immune System tables at the back of the book for related test by body system.
**Hemoglobin Electrophoresis**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

**REFERENCE VALUE:** (Method: Electrophoresis)

**DESCRIPTION:** Hemoglobin (Hgb) electrophoresis is a separation process used to identify normal and abnormal forms of Hgb. Hgb A is the main form of Hgb in the normal adult. Hgb F is the main form of Hgb in the fetus, the remainder being composed of Hgb A<sub>1</sub> and A<sub>2</sub>. Small amounts of Hgb F are normal in the adult. Hgb D, E, H, S, and C result from abnormal amino acid substitutions during the formation of Hgb and are inherited hemoglobinopathies.

**INDICATIONS:**
- Assist in the diagnosis of Hgb C disease
- Assist in the diagnosis of thalassemia, especially in patients with a family history positive for the disorder
- Differentiate among thalassemia types
- Evaluate hemolytic anemia of unknown cause
- Evaluate a positive sickle cell screening test to differentiate sickle cell trait from sickle cell disease

**RESULT:**

### Increased in:

- **Hgb A<sub>2</sub>:**
  - Megaloblastic anemia
  - Thalassemias

- **Hgb F:**
  - Acquired aplastic anemia
  - Hereditary persistence of fetal Hgb
  - Hyperthyroidism
  - Leakage of fetal blood into maternal circulation
  - Leukemia (acute or chronic)
  - Myeloproliferative disorders
  - Sickle cell disease
  - Thalassemias

Access additional resources at davisplus.fadavis.com
β-Chain substitutions:
- Hgb C (second most common variant in the United States, it has a higher prevalence among African Americans)
- Hgb C disease:
  - Hgb D (rare hemoglobinopathy that may also be found in combination with Hgb S or thalassemia)
- Splenomegaly without other significant clinical implications:
  - Hgb E (second most common hemoglobinopathy in the world, occurs with the highest frequency in Southeast Asians and African-Americans)
- Thalassemia-like condition:
  - Hgb S (most common variant in the United States, occurs with a frequency of about 8% among African Americans)
  - Hgb S disease or trait
  - α-Chain substitutions:
    - Hgb H
  - α-Thalassemias:
    - Bart’s Hgb
  - α-Thalassemias
  - Hgb Bart’s hydrops fetalis syndrome

Decreased in:
- Hgb A₂: Erythroleukemia
- Hgb H disease
- Iron-deficiency anemia (untreated)
- Sideroblastic anemia

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- High altitude and dehydration may increase values.
- Iron deficiency may decrease Hgb A₂, C, and S.
- In patients less than 3 mo of age, false-negative results for Hgb S occur in coincidental polycythemia.
- Red blood cell transfusion within 4 mo of test can mask abnormal Hgb levels.

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to identify hemoglobin variants and diagnose thalassemias.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop
Hemosiderin

SYNONYM/ACRONYM: Hemosiderin stain, Pappenheimer body stain, iron stain.
