SPECIMEN: Urine (5 mL) from a random first morning sample, collected in a clean plastic collection container.

REFERENCE VALUE: (Method: Microscopic examination of Prussian blue–stained specimen) None seen.

DESCRIPTION: Hemosiderin stain is used to indicate the presence of iron storage granules called hemosiderin by microscopic examination of urine sediment. Granules of hemosiderin stain blue when potassium ferrocyanide is added to the sample. Hemosiderin is normally found in the liver, spleen, and bone marrow, but not in the urine. Under normal conditions, hemosiderin is absorbed by the renal tubules; however, in extensive hemolysis, renal tubule damage, or an iron metabolism disorder, hemosiderin filters its way into the urine. The Prussian blue stain may also be used to identify siderocytes (iron-containing red blood cells [RBCs]) in peripheral blood. The presence of siderocytes in circulating RBCs is abnormal.

INDICATIONS:
• Assist in the diagnosis of hemochromatosis (tissue damage caused by iron toxicity)
• Detect excessive RBC hemolysis within the systemic circulation
• Evaluate renal tubule dysfunction

RELATED MONOGRAPHS:
Related tests include biopsy bone marrow, blood gases, complete blood count, complete blood count, hematocrit, complete blood count, hemoglobin, methemoglobin, osmotic fragility, complete blood count, RBC morphology, and sickle cell screen.

POST-TEST:
• A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
• Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
• Answer any questions or address any concerns voiced by the patient or family.
• Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

Related tests include biopsy bone marrow, blood gases, complete blood count, complete blood count, hematocrit, complete blood count, hemoglobin, methemoglobin, osmotic fragility, complete blood count, RBC morphology, and sickle cell screen.

Refer to the Hematopoietic System table at the back of the book for related tests by body system.
RESULT:

**Increased in:**
Any condition that involves hemo-
lysis will release hemoglobin
from RBCs into circulation. Hemo-
globin is converted to hemosiderin
in the renal tubular epithelial cells.

- Burns
- Cold hemagglutinin disease
- Hemochromatosis
- Hemolytic transfusion reactions
- Mechanical trauma to RBCs
- Megaloblastic anemia
- Microangiopathic hemolytic
anemia
- Paroxysmal nocturnal
hemoglobinuria
- Pernicious anemia
- Sickle cell anemia
- Thalassemia major

**Decreased in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:** N/A

---

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at
  least two unique identifiers before pro-
  viding care, treatment, or services.
- Inform the patient that the test is used
to indicate recent intravascular hemoly-
sis and to assist in the diagnosis of
unexplained anemia.
- Obtain a history of the patient’s com-
  plaints, including a list of known aller-
gens, especially allergies or sensitivities
to latex.
- Obtain a history of the patient’s
  hematopoietic and genitourinary sys-
  tems, especially a history of hemolytic
  anemia, symptoms, and results of pre-
  viously performed laboratory tests and
diagnostic and surgical procedures.
- Obtain a list of the patient’s current
  medications, including herbs, nutritional
  supplements, and nutraceuticals.

- Review the procedure with the
  patient. Inform the patient that speci-
  men collection takes approximately
  5 to 10 min. Address concerns about
  pain and explain that there should
  be no discomfort during the
  procedure.
- Sensitivity to social and cultural issues,
as well as concern for modesty, is im-
  portant in providing psychological support
  before, during, and after the procedure.
- There are no food, fluid, or medication
  restrictions, unless by medical
  direction.

**INTRATEST:**

- If the patient has a history of allergic
  reaction to latex, avoid the use of
  equipment containing latex.
- Instruct the patient to cooperate fully
  and to follow directions.
- Observe standard precautions, and
  follow the general guidelines in
  Appendix A. Positively identify the
  patient, and label the appropriate
  collection container with the corre-
  sponding patient demographics, date,
  and time of collection.
- Clean-Catch Specimen:
  - Instruct the male patient to (1) thor-
    oughly wash his hands, (2) cleanse the
    meatus, (3) void a small amount into
    the toilet, and (4) void directly into the
    specimen container.
  - Instruct the female patient to (1) thor-
    oughly wash her hands; (2) cleanse
    the labia from front to back; (3) while
    keeping the labia separated, void
    a small amount into the toilet; and
    (4) without interrupting the urine
    stream, void directly into the
    specimen container.
- Indwelling Catheter:
  - Put on gloves. Empty drainage tube
    of urine. It may be necessary to
    clamp off the catheter for 15 to
    30 min before specimen collection.
    Cleanse specimen port with antiseptic
    swab, and then aspirate 5 mL of urine
    with a 21- to 25-gauge needle and
    syringe. Transfer urine to a collection
    container.
- General:
  - Promptly transport the specimen to
    the laboratory for processing and
    analysis.
**HEPATITIS A ANTIBODY**

**SYNONYM/ACRONYM:** HAV serology.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** (Method: Enzyme immunoassay) Negative.

**DESCRIPTION:** The hepatitis A virus is classified as a picornavirus. Its primary mode of transmission is by the fecal-oral route under conditions of poor personal hygiene or inadequate sanitation. The incubation period is about 28 days, with a range of 15 to 50 days. Onset is usually abrupt, with the acute disease lasting about 1 wk. Therapy is supportive, and there is no development of chronic or carrier states. Assays for total (immunoglobulin G and immunoglobulin M [IgM]) hepatitis A antibody and IgM-specific hepatitis A antibody assist in differentiating recent infection from prior exposure. If results from the IgM-specific or from both assays are positive, recent infection is suspected. If the IgM-specific test results are negative and the total antibody test results are positive, past infection is indicated. The clinically significant assay—IgM-specific antibody—is often the only test requested. Jaundice occurs in 70% to 80% of adult cases of HAV infection and in 70% of pediatric cases.

Access additional resources at davisplus.fadavis.com
INDICATIONS:
• Screen individuals at high risk of exposure, such as those in long-term residential facilities or correctional facilities
• Screen individuals with suspected HAV infection

RESULT:
Positive findings in:
• Individuals with current hepatitis A infection
• Individuals with past hepatitis A infection

CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
铷 Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
铷 Inform the patient that the test is used to test blood for the presence of antibodies that would indicate past or current hepatitis A infection.
铷 Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
铷 Obtain a history of the patient’s hepatobiliary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
铷 Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
铷 Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
铷 There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
铷 If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
铷 Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
铷 Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
铷 Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
铷 Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
铷 A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
铷 Nutritional considerations: Dietary recommendations may be indicated and will vary depending on the type and severity of the condition. Elimination of alcohol ingestion and a diet optimized for convalescence are commonly included in the treatment plan.
铷 Social and cultural considerations: Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Counsel the patient, as appropriate, regarding risk of transmission and proper prophylaxis. Immune globulin can be given before exposure (in the case of individuals who may be traveling to a location where the disease is endemic) or after exposure, during the incubation period. Prophylaxis is most effective when administered 2 wk after exposure.
铷 Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Provide information regarding
vaccine-preventable diseases where indicated (e.g., encephalitis, Hepatitis A and B, human papillomavirus, influenza, measles, mumps, polio, rubella, smallpox, varicella, yellow fever). Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ALT, ALP, AST, bilirubin, GGT, and HBV and HBC antigens and antibodies.
- Refer to the Hepatobiliary and Immune System tables at the back of the book for related tests by body system.

**Hepatitis B Antigen and Antibody**

**SYNONYM/ACRONYM:** HBeAg, HBeAb, HBcAb, HBsAb, HBsAg.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** (Method: Enzyme immunoassay) Negative.

**DESCRIPTION:** The hepatitis B virus (HBV) is classified as a double-stranded DNA retrovirus of the Hepadnaviridae family. Its primary modes of transmission are parenteral, perinatal, and sexual contact. Serological profiles vary with different scenarios (i.e., asymptomatic infection, acute/resolved infection, coinfection, and chronic carrier state). The formation and detectability of markers is also dose dependent. The following description refers to HBV infection that becomes resolved. The incubation period is generally 6 to 16 wk. The hepatitis B surface antigen (HBsAg) is the first marker to appear after infection. It is detectable 8 to 12 wk after exposure and often precedes symptoms. At about the time liver enzymes fall back to normal levels, the HBsAg titer has fallen to nondetectable levels. If the HBsAg remains detectable after 6 mo, the patient will likely become a chronic carrier who can transmit the virus. Hepatitis Be antigen (HBeAg) appears in the serum 10 to 12 wk after exposure. HBeAg can be found in the serum of patients with acute or chronic HBV infection and is a sign of active viral replication and infectivity. Levels of hepatitis Be antibody (HBeAb) appear about 14 wk after exposure, suggesting resolution of the infection and reduction of the patient’s ability to transmit the disease. The more quickly HBeAg disappears, the shorter the acute phase of the infection. Immunoglobulin M–specific hepatitis B core antibody (HBcAb) appears 6 to
14 wk after exposure to HBsAg and continues to be detectable either until the infection is resolved or over the life span in patients who are in a chronic carrier state. In some cases, HBCAb may be the only detectable marker; hence, its lone appearance has sometimes been referred to as the core window. HBCAb is not an indicator of recovery or immunity; however, it does indicate current or previous infection. Hepatitis B surface antibody (HBsAb) appears 2 to 16 wk after HBsAg disappears. Appearance of HBsAb represents clinical recovery and immunity to the virus.

Onset of HBV infection is usually insidious. Most children and half of infected adults are asymptomatic. During the acute phase of infection, symptoms range from mild to severe. Chronicity decreases with age. HBsAg and HBCAb tests are used to screen donated blood before transfusion. HBsAg testing is often part of the routine prenatal screen. Vaccination of infants, children, and young adults is becoming a standard of care and in some cases a requirement.

**INDICATIONS:**
- Detect exposure to HBV
- Detect possible carrier status
- Pre- and postvaccination testing
- Routine prenatal testing
- Screen donated blood before transfusion
- Screen for individuals at high risk of exposure, such as hemodialysis patients, persons with multiple sex partners, persons with a history of other sexually transmitted diseases, IV drug abusers, infants born to infected mothers, individuals residing in long-term residential facilities or correctional facilities, recipients of blood- or plasma-derived products, allied health care workers, and public service employees who come in contact with blood and blood products.

**RESULT:**

**Positive findings in:**
- Patients currently infected with HBV
- Patients with a past HBV infection

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
Drugs that may decrease HBeAb and HBsAb include interferon.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to identify and confirm hepatitis B infection.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hepatobiliary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a history of IV drug use, high-risk sexual activity, or occupational exposure.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- **Nutritional considerations:** Dietary recommendations may be indicated and will vary depending on the type and severity of the condition. Elimination of alcohol ingestion, and a diet optimized for convalescence are commonly included in the treatment plan. A high-calorie, high-protein, moderate-fat diet with a high fluid intake is often recommended for patients with hepatitis.
- **Cultural and social considerations:** Recognize anxiety related to test results, and be supportive of impaired activity related to lack of neuromuscular control, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPH**
- Related tests include ALT, ALP, antibodies, antimitochondrial, AST, bilirubin, biopsy liver, *chlamydia* group antibody, cholangiography percutaneous transhepatic, culture anal, GGT, hepatitis C serology, HIV serology, liver and spleen scan, syphilis serology, and US liver.
  - Refer to the Hepatobiliary and Immune System tables at the back of the book for related tests by body system.

---

**Hepatitis C Antibody**

**SYNONYM/ACRONYM:** HCV serology, hepatitis non-A/non-B.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** (Method: Enzyme immunoassay, branched chain DNA [bDNA], polymerase chain reaction [PCR], recombinant immunoblot assay [RIBA]) Negative.

**DESCRIPTION:** The hepatitis C virus (HCV) causes the majority of blood-borne non-A, non-B hepatitis cases. Its primary modes of transmission are parenteral, perinatal, and sexual contact. The virus is thought to be a flavivirus and contains a single-stranded RNA core. The incubation period varies widely, from 2 to 52 wk. Onset is insidious, and the risk of chronic liver disease after infection is high. On average, antibodies to hepatitis C are detectable in approximately 45% of infected individuals within 6 wk of infection. The remaining 55% produce antibodies within the next 6 to 12 mo. Once infected with HCV, 50% of patients will become chronic carriers. Infected individuals and carriers have a high frequency of chronic liver diseases such as cirrhosis and chronic active hepatitis, and they have a higher risk of developing hepatocellular cancer. The transmission of hepatitis C by blood transfusion has decreased dramatically since it became part of the routine screening panel for blood donors. The possibility of prenatal transmission exists, especially in the presence of HIV coinfection. Therefore, this test is often included in prenatal testing packages. Currently, nucleic acid amplification testing (NAT) is the only way to document the presence of ongoing infection. PCR and bDNA methods are recognized by the Centers of Disease Control (CDC) as appropriate supplemental testing for the confirmation of anti-HCV antibody.
INDICATIONS:
• Assist in the diagnosis of non-A, non-B viral hepatitis infection
• Monitor patients suspected of HCV infection but who have not yet produced antibody
• Routine prenatal testing
• Screen donated blood before transfusion

RESULT:
Positive findings in:
• Patients currently infected with HCV
• Patients with a past HCV infection

Negative findings in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
Drugs that may decrease hepatitis C antibody levels include interferon.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to identify and confirm hepatitis C infection.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s hepatobiliary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Obtain a history of IV drug use, high-risk sexual activity, and occupational exposure.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
• If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
• Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
• Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
• Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
• Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
• A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Nutritional considerations: Dietary recommendations may be indicated and will vary depending on the type and severity of the condition. Currently, for example, there are no specific medications that can be given to cure hepatitis; however, bed rest, elimination of alcohol ingestion, and a diet optimized for convalescence are commonly included in the treatment plan. A high-calorie, high-protein, moderate-fat diet with a high fluid intake is often recommended for patients with hepatitis.

Cultural and social considerations: Recognize anxiety related to test results, and be supportive of impaired activity related to lack of neuromuscular...
Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Counsel the patient, as appropriate, regarding the risk of transmission and proper prophylaxis. Interferon alfa was approved in 1991 by the U.S. Food and Drug Administration for use as a therapeutic agent in the treatment of chronic HCV infection.

Inform the patient that positive findings must be reported to local health department officials, who will question him or her regarding sexual partners.

Sensitivity to social and cultural considerations: Offer support, as appropriate, to patients who may be the victims of rape or other forms of sexual assault, including children and elderly individuals. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nonthreatening atmosphere for a discussion during which the risks of sexually transmitted diseases are explained. It is also important to discuss the problems that the patient may experience (e.g., guilt, depression, anger).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

 RELATED MONOGRAPHS:

Related tests include ALT, ALP, antibodies, antimitochondrial, AST, bilirubin, biopsy liver, chlamydia group antibody, cholangiography percutaneous transhepatic, culture anal, GGT, hepatitis B serology, hepatobiliary scan, HIV serology, liver and spleen scan, syphilis serology, and US liver.

Refer to the Hepatobiliary and Immune System tables at the back of the book for related tests by body system.

RESULT:

Positive findings in:

• Individuals currently infected with HDV

• Individuals with a past HDV infection

CRITICAL VALUES: N/A

**Hepatobiliary Scan**

**SYNONYM/ACRONYM:** Hepatobiliary imaging, biliary tract radionuclide scan, hepatobiliary scintigraphy, gallbladder scan, cholescintigraphy, HIDA (a technetium-99m disopropyl analogue) scan.

**AREA OF APPLICATION:** Bile ducts.

**CONTRAST:** IV contrast medium (aminodiacetic acid compounds), usually combined with technetium-99m.

**DESCRIPTION:** The hepatobiliary scan is a nuclear medicine study of the hepatobiliary excretion system. It is primarily used to determine the patency of the cystic and common bile ducts, but it can also be used to determine overall hepatic function, gallbladder function, presence of gallstones (indirectly), and sphincter of Oddi dysfunction. Technetium (Tc-99m) HIDA (tribromoethyl, an aminodiacetic acid) is injected IV and excreted into the bile duct system. A gamma camera detects the radiation emitted from the injected contrast medium, and a representative image of the duct system is obtained. The results are correlated with other diagnostic studies, such as IV cholangiography, computed tomography (CT) scan of the gallbladder, and ultrasonography. Gallbladder emptying or ejection fraction can be determined by administering a fatty meal or cholecystokinin to the patient. This procedure can be used before and after surgery to determine the extent of bile reflux.
INTERFERING FACTORS:

**This procedure is contraindicated for:**
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

**Factors that may impair the results of the examination:**
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Retained barium from a previous radiological procedure
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Bilirubin levels greater than or equal to 30 mg/dL, depending on the radionuclide used, which may decrease hepatic uptake
- Other nuclear scans done within the previous 24 to 48 hr
- Fasting for more than 24 hr before the procedure, total parenteral nutrition, and alcoholism
- Ingestion of food or liquids within 2 to 4 hr before the scan

**Other considerations:**
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue can produce erroneous hot spots.
- Inaccurate timing of imaging after the radionuclide injection can affect the results.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures.
- Personnel in the room with the patient should stand behind a shield, or leave the area while the examination is being done.
- Personnel working in the examination area should wear badges to record their level of radiation exposure.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure detects inflammation or obstruction of the gallbladder or bile duct system.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- Obtain a history of results of the patient’s hepatobiliary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain and explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in a nuclear medicine department by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
Inform the patient that the HCP will place him or her in a supine position on a flat table.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.

Instruct the patient to restrict food and fluids for 4 to 6 hr prior to the procedure. Protocols may vary from facility to facility.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure that the patient has complied with dietary, fluids, and medication restrictions for 4 to 6 hr prior to the procedure.
- Ensure that the patient has removed all external metallic objects prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to lie still during the procedure because movement produces unclear images.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in a supine position on a flat table with foam wedges to help maintain position and immobilization.
- IV radionuclide is administered, and the upper right quadrant of the abdomen is scanned immediately, with images then taken every 5 min for the first 30 min and every 10 min for the next 30 min. Delayed views are taken in 2, 4, and 24 hr if the gallbladder cannot be visualized, in order to differentiate acute from chronic cholecystitis or to detect the degree of obstruction.
- IV morphine may be administered during the study to initiate spasms of the sphincter of Oddi, forcing the radionuclide into the gallbladder, if the organ is not visualized within 1 hr of injection of the radionuclide. Imaging is then done 20 to 50 min later to determine delayed visualization or nonvisualization of the gallbladder.
- If gallbladder function or bile reflux is being assessed, the patient will be given a fatty meal or cholecystokinin 60 min after the injection.
- If gallbladder function or bile reflux is being assessed, the patient will be given a fatty meal or cholecystokinin 60 min after the injection.
- Remove the needle or catheter and apply a pressure dressing over the puncture site.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- Instruct the patient to resume usual diet, fluids, medications, and activity as directed by the HCP.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the injection site.
- Observe for bleeding, hematoma formation, and inflammation.
- If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- Instruct the patient to immediately flush the toilet and to meticulously...
wash hands with soap and water after each voiding for 24 hr after the procedure.

- Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash ungloved hands after the gloves are removed.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.

Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include amylase, bilirubin, CT abdomen, lipase, liver and spleen scan, MRI abdomen, radiofrequency ablation liver, and US liver and bile ducts.
- Refer to the Hepatobiliary System table at the back of the book for related tests by body system.

### Hexosaminidase A and B

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Serum (3 mL) collected in a red-top tube. After the specimen is collected, it must be brought immediately to the laboratory. Once in the laboratory, the specimen must be allowed to clot for 1 to 1.5 hr in the refrigerator. The serum should then be removed and frozen immediately.

**REFERENCE VALUE:** (Method: Fluorometry)

Hexosaminidase A and B

**DESCRIPTION:** Hexosaminidase is a lysosomal enzyme. There are three predominant isoenzymes: hexosaminidase A, B, and S. Deficiency results in the accumulation of complex sphingolipids and gangliosides in the brain. There are more than 70 lysosomal enzyme disorders. Testing for hexosaminidase A is done to determine the presence of Tay-Sachs disease, a genetic autosomal recessive condition characterized by early and progressive retardation of physical and mental development. This enzyme deficiency is most common among Ashkenazi Jews. Patients who are homozygous for this trait have no hexosaminidase A and have greatly elevated levels of hexosaminidase B; signs and symptoms include red spot in the retina, blindness, and muscular weakness. Tay-Sachs disease results in early death, usually by age 3 or 4.

**INDICATIONS:**
- Assist in the diagnosis of Tay-Sachs disease
- Identify carriers with hexosaminidase deficiency

**RESULT:**
**Increased in:**
Alterations in lysosomal enzymes metabolism are associated with various conditions.
- Total:
  - Gastric cancer

**INTERFERING FACTORS:**
Drugs that may increase hexosaminidase levels include ethanol, isoniazid, oral contraceptives, and rifampin.

**CRITICAL VALUES:** N/A

**DESCRIPTION:**
 Hepatic disease  
 Myeloma  
 Myocardial infarction  
 Pregnancy  
 Symptomatic porphyria  
 Vascular complications of diabetes

- Hexosaminidase A:  
  - Diabetes  
  - Pregnancy  

- Hexosaminidase B:  
  - Tay-Sachs disease

**Decreased in:**
- Total  
  - Sandhoff’s disease *(Inherited disorder of enzyme metabolism lacking both essential enzymes for metabolizing gangliosides)*  

- Hexosaminidase A:  
  - Tay-Sachs disease *(Inherited disorder of enzyme metabolism lacking only the hexosaminidase A enzyme for metabolizing gangliosides)*  

- Hexosaminidase B:  
  - Sandhoff’s disease

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

Access additional resources at davisplus.fadavis.com
Inform the patient that the test is used to identify carrier status for Tay-Sachs disease.

Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient’s reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage. Immediately transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Encourage the family to seek genetic counseling if results are abnormal. It is also important to discuss feelings the mother and father may experience (e.g., guilt, depression, anger) if abnormalities are detected. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the National Tay Sachs and Allied Diseases Association (www.ntsad.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include ALT, amniotic fluid analysis, bilirubin, biopsy chorionic villus, biopsy liver, blood pool imaging, cancer antigens, capsule endoscopy, ceruloplasmin, chromosome analysis, CT cardiac scoring, CK and isoenzymes, GGT, gastric acid stimulation, gastrin stimulation, GH, Helicobacter pylori, Holter monitor, liver and spleen scan, myocardial infarction scan, myocardial perfusion scan, myoglobin, PET heart, protein total and fractions, radiography bone, troponin, upper GI series, and complete blood count, WBC count and differential.

Refer to the Reproductive System table at the back of the book for related tests by body system.
**Holter Monitor**

**SYNONYM/ACRONYM:** Holter electrocardiography, ambulatory monitoring, ambulatory electrocardiography, event recorder.

**AREA OF APPLICATION:** Heart.

**CONTRAST:** None.

**DESCRIPTION:** The Holter monitor records electrical cardiac activity on a continuous basis for 24 to 48 hr. This noninvasive study includes the use of a portable device worn around the waist or over the shoulder that records cardiac electrical impulses on a magnetic tape. The recorder has a clock that allows accurate time markings on the tape. The patient is asked to keep a log or diary of daily activities and to record any occurrence of cardiac symptoms. When the client pushes a button indicating that symptoms (e.g., pain, palpitations, dyspnea, syncope) have occurred, an event marker is placed on the tape for later comparison with the cardiac activity recordings and the daily activity log. Some recorders allow the data to be transferred to the physician’s office by telephone, where the tape is interpreted by a computer to detect any significantly abnormal variations in the recorded waveform patterns.

**INDICATIONS:**
- Detect arrhythmias that occur during normal daily activities, and correlate them with symptoms experienced by the patient
- Evaluate activity intolerance related to oxygen supply and demand imbalance
- Evaluate chest pain, dizziness, syncope, and palpitations
- Evaluate the effectiveness of antiarrhythmic medications for dosage adjustment, if needed
- Evaluate pacemaker function
- Monitor for ischemia and arrhythmias after myocardial infarction or cardiac surgery before changing rehabilitation and other therapy regimens

**RESULT:**

**Normal findings in:**
- Normal sinus rhythm

**Abnormal findings in:**
- Arrhythmias such as premature ventricular contractions, bradyarrhythmias, tachyarrhythmias, conduction defects, and bradycardia
- Cardiomyopathy
- Hypoxic or ischemic changes
- Mitral valve abnormality
- Palpitations

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

**Factors that may impair the results of the examination:**
- Improper placement of the electrodes or movement of the electrodes
- Failure of the patient to maintain a daily log of symptoms or to push the button to produce a mark on the strip when experiencing a symptom

Access additional resources at davisplus.fadavis.com
Positively identify the patient using at least two unique identifiers before providing care, treatment, or services. Inform the patient that the procedure evaluates the heart’s response to normal activity or to a medication regimen.

Obtain a history of the patient’s complaints or symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast mediums. Obtain a history of the patient’s cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals. Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no electricity is delivered to the body during this procedure and no discomfort is experienced during monitoring. Inform the patient that the electrocardiography (ECG) recorder is worn for 24 to 48 hr, at which time the patient is to return to the laboratory with an activity log to have the monitor and strip removed for interpretation.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient to wear loose-fitting clothing over the electrodes and not to disturb or disconnect the electrodes or wires.

Advise the patient to avoid contact with electrical devices that can affect the strip tracings (e.g., shavers, toothbrush, massager, blanket) and to avoid showers and tub bathing.

Instruct the patient to perform normal activities, such as walking, sleeping, climbing stairs, sexual activity, bowel or urinary elimination, cigarette smoking, emotional upsets, and medications, and to record them in an activity log.

Instruct the patient regarding recording and pressing the button upon experiencing pain or discomfort.

Advise the patient to report a light signal on the monitor, which indicates equipment malfunction or that an electrode has come off.

There are no food, fluid, or medication restrictions, unless by medical direction.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions.

Observe standard precautions, and follow the general guidelines in Appendix A.

Place the patient in a supine position.

Expose the chest. Shave excessive hair at the skin sites; cleanse thoroughly with alcohol and rub until red in color.

Apply electropaste to the skin sites to provide conduction between the skin and electrodes, or apply prelubricated disk electrodes that are disposable.

Apply two electrodes (negative electrodes) on the manubrium, one in the V1 position (fourth intercostal space at the border of the right sternum), and one at the V5 position (level of the fifth intercostal space at the midclavicular line, horizontally and at the left axillary line). A ground electrode is also placed and secured to the skin of the chest or abdomen.

After checking to ensure that the electrodes are secure, attach the electrode cable to the monitor and the lead wires to the electrodes.

Check the monitor for paper supply and battery, insert the tape, and turn on the recorder. Tape all wires to the chest, and place the belt or shoulder strap in the proper position.

After the patient has worn the monitor for the required 24 to 48 hr, gently remove the tape and other items securing the electrodes to him or her.

The activity log and tape recording are compared for changes during the monitoring period.

A report of the examination will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Advise the patient to immediately report symptoms such as fast heart rate or difficulty breathing.
Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include antiarrhythmic drugs, blood pool imaging, calcium, chest x-ray, echocardiography, echocardiography transesophageal, electrocardiogram, exercise stress test, magnesium, myocardial perfusion heart scan, PET heart, and potassium.
- Refer to the Cardiovascular System table at the back of the book for related tests by body system.

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Serum (4 mL) collected in a red- or tiger-top tube if methylmalonic acid and homocysteine are to be measured together. Alternatively, plasma collected in a lavender-top (EDTA) tube may be acceptable for the homocysteine measurement. The laboratory should be consulted before specimen collection because specimen type may be method dependent. Care must be taken to use the same type of collection container if serial measurements are to be taken.

**REFERENCE VALUE:** (Method: Chromatography) Homocysteine: 4.6–11.2 micro-mol/L; methylmalonic acid: 70–270 nmol/L.

**DESCRIPTION:** Homocysteine is an amino acid formed from methionine. Normally homocysteine is rapidly remetabolized in a biochemical pathway that requires vitamin B₁₂ and folate, preventing the buildup of homocysteine in the blood. Excess levels damage the endothelial lining of blood vessels; change coagulation factor levels, increasing the risk of blood clot formation; prevent smaller arteries from dilating, increasing the risk of plaque formation; cause platelet aggregation; and cause smooth muscle cells lining the arterial wall to multiply, promoting atherosclerosis.

Approximately one-third of patients with hyperhomocystinuria have normal fasting levels. Patients with a heterozygous biochemical enzyme defect in cystathionine B synthase or with a nutritional deficiency in vitamin B₆ can be identified through the administration of a
methionine challenge or loading test. Specimens are collected while fasting and 2 hr later. An increase in homocysteine after 2 hr is indicative of hyperhomocystinuria. In patients with vitamin B₁₂ deficiency, elevated levels of methylmalonic acid and homocysteine develop fairly early in the course of the disease. Unlike vitamin B₁₂, levels, homocysteine levels will remain elevated for at least 24 hr after the start of vitamin therapy. This may be useful if vitamin therapy is inadvertently begun before specimen collection. Patients with folate deficiency, for the most part, will only develop elevated homocysteine levels. Hyperhomocysteinemia due to folate deficiency in pregnant women is believed to increase the risk of neural tube defects. Elevated levels of homocysteine are thought to chemically damage the exposed neural tissue of the developing fetus.

**INDICATIONS:**
- Evaluate inherited enzyme deficiencies that result in homocystinuria
- Evaluate the risk for cardiovascular disease
- Evaluate the risk for venous thrombosis

**RESULT:**

**Increased in:**
- Chronic renal failure (*Pathophysiology is unclear*)
- Coronary artery disease (CAD) (*There is a relationship but the pathophysiology is not clear*)
- Folic acid deficiency (*Folate is required for completion of biochemical reactions involved in homocysteine metabolism*)
- Homocystinuria (*Inherited disorder of methionine metabolism*

**that results in accumulation of homocysteine**
- Vitamin B₁₂ deficiency (*Vitamin B₁₂ is required for completion of biochemical reactions involved in homocysteine metabolism*)

**Decreased in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase plasma homocysteine levels include anti-convulsants, cycloserine, hydralazine, isoniazid, methotrexate, penicillamine, phenelzine, and theophylline.
- Specimens should be kept at a refrigerated temperature and delivered immediately to the laboratory for processing.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to screen for risk of cardiovascular disease and stroke.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular and hematopoietic systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological
support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen for combined methylmalonic acid and homocysteine studies in two 5-mL red- or tiger-top tubes. If only homocysteine is to be measured, a 5-mL lavender-top tube is acceptable.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- **Nutritional considerations:** Increased homocysteine levels may be associated with atherosclerosis and CAD. Nutritional therapy is recommended for individuals identified to be at high risk for developing CAD. If overweight, these patients should be encouraged to achieve a normal weight. The American Heart Association has Step 1 and Step 2 diets that may be helpful in achieving a goal of lowering total cholesterol and triglyceride levels. The Step 1 diet emphasizes a reduction in foods high in saturated fats and cholesterol. Red meats, eggs, and dairy products are the major sources of saturated fats and cholesterol. If triglycerides are also elevated, patients should be advised to eliminate or reduce alcohol and simple carbohydrates from their diet. The Step 2 diet recommends stricter reductions.
- **Nutritional considerations:** Diets rich in fruits, grains, and cereals, in addition to a multivitamin containing B12 and folate, may be recommended for patients with elevated homocysteine levels. Processed and refined foods should be kept to a minimum.
- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org).
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, ANP, blood gases, BMD, BNP, BUN, calcitonin, calcium, cholesterol (total, HDL, and LDL), complete blood count, complete blood count, RBC count, complete blood count, RBC indices, complete blood count, RBC morphology, complete blood count, WBC count and differential, CRP, CK and isoenzymes, creatinine, folate, glucose, glycated hemoglobin, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, myoglobin, osteocalcin, PTH, pericardial fluid analysis, potassium, prealbumin, renogram, triglycerides, troponin, US kidney, UA, and vitamin B12.
- Refer to the Cardiovascular and Hematopoietic System tables at the back of the book for related tests by body system.
Homovanillic Acid

SYNONYM/ACRONYM: HVA.

SPECIMEN: Urine (10 mL) from a timed specimen collected in a clean plastic collection container with 6N HCl as a preservative.

REFERENCE VALUE: (Method: Chromatography)

**DESCRIPTION:** Homovanillic acid (HVA) is the main terminal metabolite of dopamine. Vanillylmandelic acid is a major metabolite of epinephrine and norepinephrine. Both of these tests should be evaluated together for the diagnosis of neuroblastoma. Excretion may be intermittent; therefore, a 24-hour specimen is preferred. Creatinine is usually measured simultaneously to ensure adequate collection and to calculate an excretion ratio of metabolite to creatinine.

**RESULT:**

*Increased in:*

HVA is excreted in excessive amounts in the following conditions:
- Ganglioblastoma
- Neuroblastoma
- Pheochromocytoma
- Riley-Day syndrome

*Decreased in:*

- Schizotypal personality disorders

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase HVA levels include acetylsalicylic acid, disulfiram, levodopa, pyridoxine, and reserpine.
- Drugs that may decrease HVA levels include moclobemide.
- All urine voided for the timed collection period must be included.
in the collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

**NURSING IMPLICATIONS ANDPROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to diagnose neuroblastoma, pheochromocytoma, and ganglioblastoma, and to monitor therapy.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.
- Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- If possible, and with medical direction, patients should withhold acetylsalicylic acid, disulfiram, pyridoxine, and reserpine for 2 days before specimen collection. Levodopa should be withheld for 2 wk before specimen collection.
- There are no food or fluid restrictions, unless by medical direction.

**INTRATEST:**
- Ensure that the patient has complied with medication restrictions; assure that specified medications, with medical direction, have been restricted for at least 2 days prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection.

**Timed Specimen:**
- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 a.m. and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the
beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time. If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger refrigerated container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.

At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.

Include on the collection container’s label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

➤ A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

➤ Instruct the patient to resume usual medications, as directed by the HCP.

➤ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

➤ Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

➤ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

➤ Related tests include angiography adrenal, CEA, catecholamines, CT renal, metanephrines, renin, and VMA.

➤ Refer to the Endocrine System table at the back of the book for related tests by body system.

---

**Human Chorionic Gonadotropin**

**SYNONYM/ACRONYM:** Chorionic gonadotropin, pregnancy test, HCG, hCG, α-HCG, β-subunit HCG.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

**REFERENCE VALUE:** (Method: Immunoassay)
DESCRIPTION: Human chorionic gonadotropin (HCG) is a hormone secreted by the placenta beginning 8 to 10 days after conception, which coincides with implantation of the fertilized ovum. It stimulates secretion of progesterone by the corpus luteum. HCG levels peak at 8 to 12 wk of gestation and then fall to less than 10% of first trimester levels by the end of pregnancy. By postpartum wk 2, levels are undetectable. HCG levels increase at a slower rate in ectopic pregnancy and spontaneous abortion than in normal pregnancy; a low rate of change between serial specimens is predictive of a nonviable fetus. As assays improve in sensitivity over time, ectopic pregnancies are increasingly being identified before rupture. HCG is used along with α-fetoprotein, dimeric inhibin-A, and estriol in prenatal screening for neural tube defects.

These prenatal measurements are also known as triple or quad markers, depending on which tests are included. Serial measurements are needed for an accurate estimate of gestational stage and determination of fetal viability. Triple- and quad-marker testing has also been used to screen for trisomy 21 (Down syndrome). (To compare HCG to other tests in the triple- and quad-marker screening procedure, see monograph titled “α₁-Fetoprotein.”) HCG is also produced by some germ cell tumors. Most assays measure both the intact and free β-HCG subunit, but if HCG is to be used as a tumor marker, the assay must be capable of detecting both intact and free β-HCG.

INDICATIONS:
- Assist in the diagnosis of suspected HCG-producing tumors,
such as choriocarcinoma, germ cell tumors of the ovary and testes, or hydatidiform moles
• Confirm pregnancy, assist in the diagnosis of suspected ectopic pregnancy, or determine threatened or incomplete abortion
• Determine adequacy of hormonal levels to maintain pregnancy
• Monitor effects of surgery or chemotherapy
• Monitor ovulation induction treatment
• Prenatally detect neural tube defects and trisomy 21 (Down syndrome)

RESULT:

Increased in:
• Choriocarcinoma (HCG-producing tumor)
• Ectopic HCG-producing tumors (stomach, lung, colon, pancreas, liver, breast)
• Erythroblastosis fetalis (Hemolytic anemia as a result of fetal sensitization by incompatible maternal blood group antigens such as Rh, Kell, Kidd, Duffy is associated with increased HCG levels)
• Germ cell tumors (ovary and testes) (HCG-producing tumors)
• Hydatidiform mole (HCG-secreting mole)
• Islet cell tumors (HCG-producing tumors)
• Multiple gestation pregnancy (Related to increased levels produced by the presence of multiple fetuses)
• Pregnancy (Related to increased production by placenta)

Decreased in:
Any condition associated with diminished viability of the placenta will reflect decreased levels.
• Ectopic pregnancy (HCG levels increase slower than in viable intrauterine pregnancies, plateau, and then decrease prior to rupture)
• Incomplete abortion
• Intrauterine fetal demise
• Spontaneous abortion
• Threatened abortion

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may decrease HCG levels include epostane and mifepristone.
• Results may vary widely depending on the sensitivity and specificity of the assay. Performance of the test too early in pregnancy may cause false-negative results. HCG is composed of an α and a β subunit. The structure of the α subunit is essentially identical to the β subunit of follicle-stimulating hormone, luteinizing hormone, and thyroid-stimulating hormone. The structure of the β subunit differentiates HCG from the other hormones. False-positive results can therefore be obtained if the HCG assay does not detect β subunit.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient, as appropriate, that the test is used to verify pregnancy, screen for neural tube defects, or detect HCG-secreting tumors.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s endocrine, immune, and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

**Social and cultural considerations:** Recognize anxiety related to abnormal test results, and encourage the family to seek counseling if concerned with pregnancy termination or to seek genetic counseling if a chromosomal abnormality is determined. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Decisions regarding elective abortion should take place in the presence of both parents. Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks and difficulties of delivering and raising a developmentally challenged infant, as well as exploring other options (termination of pregnancy or adoption). It is also important to discuss feelings the mother and father may experience (e.g., guilt, depression, anger) if fetal abnormalities are detected.

**Social and cultural considerations:** Offer support, as appropriate, to patients who may be the victims of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nonthreatening atmosphere for a discussion during which risks of sexually transmitted diseases are explained. It is also important to discuss problems the victim of sexual assault may experience (e.g., guilt, depression, anger) if there is possibility of pregnancy related to the assault.

**Social and cultural considerations:** In patients with carcinoma, recognize anxiety related to test results and offer support. Provide teaching and information regarding the clinical implications of abnormal test results, as appropriate. Educate the patient regarding access to counseling services, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor the patient’s condition and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
Related laboratory tests include biopsy choriocarcinoma villus, Chlamydia group antibody, chromosome analysis, CMV, estradiol, fetal fibronectin, α₁-fetoprotein, complete blood count, hematocrit, complete blood count, hemoglobin, progesterone, rubella antibody, rubella antibody, syphilis serology, toxoplasma antibody, US biophysical profile obstetric, and complete blood count, WBC count and differential.
Refer to the Endocrine, Immune, and Reproductive System tables at the back of the book for related tests by body system.

Access additional resources at davisplus.fadavis.com
Human Immunodeficiency Virus Type 1 and Type 2 Antibodies

**SYNONYM/ACRONYM:** HIV-1/HIV-2.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Enzyme immunoassay) Negative.

**DESCRIPTION:** Human immunodeficiency virus (HIV) is the etiologic agent of AIDS and is transmitted through bodily secretions, especially by blood or sexual contact. The virus preferentially binds to the T4 helper lymphocytes and replicates within the cells. Current assays detect several viral proteins. Positive results should be confirmed by Western blot assay. This test is routinely recommended as part of a prenatal work-up and is required for evaluating donated blood units before release for transfusion. The Centers for Disease Control and Prevention (CDC) has structured its recommendations to increase identification of HIV-infected patients as early as possible; early identification increases treatment options, increases frequency of successful treatment, and can decrease further spread of disease. Current recommendations presented in Advancing HIV Prevention: New Strategies for a Changing Epidemic 2003–2005 (www.cdc.gov):

- Include HIV testing in routine medical care; screening of all patients between the ages of 13 and 64 years of age as part of routine medical care.
- Implement new models to diagnose HIV infections outside medical settings; availability of rapid waived testing kits like OraQuick®.
- Prevent new infections by working with persons diagnosed with HIV and their partners; adapt a voluntary opt-out approach that includes elimination of pretest counseling and written consent requirements.
- Further decrease prenatal transmission of HIV by incorporating HIV testing as a routine part of prenatal medical care.

**INDICATIONS:**

- Evaluate donated blood units before transfusion
- Perform as part of prenatal screening
- Screen organ transplant donors
- Test individuals who have documented and significant exposure to other infected individuals
- Test exposed high-risk individuals for detection of antibody (e.g., persons with multiple sex partners, persons with a history of other sexually transmitted diseases, IV drug users, infants born to infected mothers, allied health care workers, public service employees who have contact with blood and blood products)
RESULT:

Positive findings in: HIV-1 or HIV-2 infection

CRITICAL VALUES: N/A

INTERFERING FACTORS:

• Drugs that may decrease HIV antibody levels include didanosine, dideoxycytidine, zalcitabine, and zidovudine.
• Nonreactive HIV test results occur during the acute stage of the disease, when the virus is present but antibodies have not sufficiently developed to be detected. It may take up to 6 mo for the test to become positive. During this stage, the test for HIV antigen may not confirm an HIV infection.
• Test kits for HIV are very sensitive. As a result, nonspecific reactions may occur, leading to a false-positive result.

INTRATEST:

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Warn the patient that false-positive results occur and that the absence of antibody does not guarantee absence of infection, because the virus may be latent or may not have produced detectable antibody at the time of testing.

Social and cultural considerations:
Recognize anxiety related to test results, and be supportive of impaired activity related to weakness, perceived loss of independence, and fear of shortened life expectancy.

Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Access additional resources at davisplus.fadavis.com
Educate the patient regarding access to counseling services. Provide contact information, if desired, for AIDS information provided by the National Institutes of Health (www.aidsinfo.nih.gov).

**Social and cultural considerations:**
Counsel the patient, as appropriate, regarding risk of transmission and proper prophylaxis, and reinforce the importance of strict adherence to the treatment regimen, including consultation with a pharmacist.

**Social and cultural considerations:**
Inform patient that positive findings must be reported to local health department officials, who will question him or her regarding sexual partners.

**Social and cultural considerations:**
Offer support, as appropriate, to patients who may be the victims of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nonthreatening atmosphere for a discussion during which risks of sexually transmitted diseases are explained. It is also important to discuss problems the patient may experience (e.g., guilt, depression, anger).

Inform the patient that retesting may be necessary.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include biopsy bone marrow, bronchoscopy, CD4/CD8 enumeration, *Chlamydia* group antibody, complete blood count, culture and smear mycobacteria, culture viral, cytology sputum, CMV, culture skin, gallium scan, HBV antibody and antigen, HCV antibody, human T-cell lymphotropic virus types I and II, laparoscopy abdominal, LAP, lymphangiogram, MRI musculoskeletal, mediastinoscopy, $\beta_2$-microglobulin, complete blood count, platelet count, syphilis serology, and complete blood count, WBC count and differential.

Refer to the Immune and Reproductive System tables at the back of the book for related tests by body system.

**Human Leukocyte Antigen B27**

**SYNONYM/ACRONYM:** HLA-B27.

**SPECIMEN:** Whole blood (5 mL) collected in green-top (heparin) or yellow-top (acid-citrate-dextrose [ACD]) tube.

**REFERENCE VALUE:** (Method: Flow cytometry) Negative (indicating absence of the antigen).

**DESCRIPTION:** The human leukocyte antigens (HLAs) are gene products of the major histocompatibility complex, derived from their respective loci on the short arm of chromosome 6. There are more than 27 identified HLAs. HLA-B27 is an allele (one of two or more genes for an inheritable trait that occupy the
same location on each chromosome, paternal and maternal) of the HLA-B locus. The antigens are present on the surface of nucleated tissue cells as well as on white blood cells. HLA testing is used in determining histocompatibility for organ and tissue transplantation. Another application for HLA testing is in paternity investigations. The presence of HLA-B27 is associated with several specific conditions, but HLA-B27 should not be used as a screening test for these conditions.

**INDICATIONS:**
Assist in diagnosing ankylosing spondylitis and Reiter’s syndrome

**RESULT:**

*Positive findings in:*
- Ankylosing spondylitis
- Juvenile rheumatoid arthritis
- Psoriatic arthritis
- Reiter’s syndrome

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- The specimen should be stored at room temperature and should be received by the laboratory performing the assay within 24 hr of collection. It is highly recommended that the laboratory be contacted before specimen collection to avoid specimen rejection.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate ankylosing spondylitis and other disorders associated with HLA-B27.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider...
(HCP), who will discuss the results with the patient.

Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. These diseases can be moderately to severely debilitating, resulting in significant lifestyle changes. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that false-positive test results occur and that retesting may be required. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ANA, complete blood count, CT spine, ESR, MRI musculoskeletal, radiography bone, and RF.
- Refer to the Immune and Musculoskeletal System tables at the back of the book for related tests by body system.

---

### Human T-Lymphotrophic Virus Type I and Type II Antibodies

**SYNONYM/ACRONYM:** HTLV-I/HTLV-II.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Enzyme immunoassay) Negative.

**DESCRIPTION:** Human T-lymphotropic virus type I (HTLV-I) and type II (HTLV-II) are two closely related retroviruses known to remain latent for extended periods before becoming reactive. The viruses are transmitted by sexual contact, contact with blood, placental transfer from mother to fetus, or ingestion of breast milk. As with HIV-1 and HIV-2, HTLV targets the T4 lymphocytes. The disease is uncommon in the United States, but retrospective studies conducted by the American Red Cross demonstrated that a small percentage of transfusion recipients became infected by HTLV-positive blood. The results of this study led to a requirement that all donated blood units be tested for HTLV-I/HTLV-II before release for transfusion.

**INDICATIONS:**

- Distinguish HTLV-I/HTLV-II infection from spastic myelopathy
• Establish HTLV-I as the causative agent in adult lymphoblastic (T-cell) leukemia
• Evaluate donated blood units before transfusion
• Evaluate HTLV-II as a contributing cause of chronic neuromuscular disease

RESULT:

Positive findings in:
• HTLV-I/HTLV-II infection

CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➧ Inform the patient that the test is used to test blood for the presence of antibodies that would indicate past or current HTLV infection.
➧ Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
➧ Obtain a history of the patient’s immune system, a history of high-risk behaviors, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
➧ Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
➧ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

➧ If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
➧ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
➧ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
➧ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
➧ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

➧ A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
➧ Warn the patient that false-positive results occur and that the absence of antibody does not guarantee absence of infection, because the virus may be latent or not have produced detectable antibody at the time of testing.

Social and cultural considerations:
Recognize anxiety related to test results, and be supportive of impaired activity related to weakness, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of positive test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Social and cultural considerations:
Counsel the patient, as appropriate, regarding risk of transmission and proper prophylaxis, and reinforce the importance of strict adherence to the
treatment regimen, including consultation with a pharmacist.
Inform the patient that the presence of HTLV-I/HTLV-II antibodies precludes blood donation, but it does not mean that leukemia or a neurological disorder is present or will develop.
Inform the patient that subsequent retesting may be necessary.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include complete blood count, hepatitis B, C, and D antigens and antibodies, and HIV-1/HIV-2.
- Refer to the Immune System table at the back of the book for related tests by body system.

**5-Hydroxyindoleacetic Acid**

**SYNONYM/ACRONYM:** 5-HIAA.

**SPECIMEN:** Urine (10 mL) from a timed specimen collected in a clean plastic collection container with boric acid as a preservative.

**REFERENCE VALUE:** (Method: High-pressure liquid chromatography)

<table>
<thead>
<tr>
<th>Conventional Units</th>
<th>SI Units (Conventional Units × 5.23)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2–7 mg/24 hr</td>
<td>10.5–36.6 micromol/24 hr</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Because 5-hydroxyindoleacetic acid (5-HIAA) is a metabolite of serotonin, 5-HIAA levels reflect plasma serotonin concentrations. 5-HIAA is excreted in the urine. Increased urinary excretion occurs in the presence of carcinoid tumors. This test, which replaces serotonin measurement, is most accurate when obtained from a 24-hr urine specimen.

**RESULT:**

*Increased in:*
Serotonin is produced by the enterochromaffin cells of the small intestine and secreted ectopically by tumor cells. It is converted to 5-HIAA in the liver and excreted in the urine. Increased values are associated with malabsorption conditions but the relationship is not clear.

- Celiac and tropical sprue
- Cystic fibrosis
- Foregut and midgut carcinoid tumors
- Oat cell carcinoma of the bronchus

**INDICATIONS:**
Detect early, small, or intermittently secreting carcinoid tumors
• Ovarian carcinoid tumors
• Whipple’s disease

**Decreased in:**
The documented relationship between decreased levels of serotonin, defective amino acid metabolism, and mental illness is not clear.

- Depressive illnesses
- Hartnup disease
- Mastocytosis
- Phenylketonuria
- Renal disease (Related to decreased renal excretion)
- Small intestine resection (Related to a decrease in enterochromaffin-producing cells)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

- Drugs that may increase 5-HIAA levels include acetaminophen, cisplatin, ephedrine, fluorouracil, cough syrups containing glyceryl guaiacolate, melphalan, mephenesin, methocarbamil, naproxen, phenacetin, pindolol, and rauwolfia alkaloids.
- Drugs that may decrease 5-HIAA levels include corticotropin, ethanol, imipramine, isoniazid, levodopa, methenamine, methyldopa, monoamine oxidase inhibitors, and phenothiazines.
- Foods containing serotonin, such as avocados, bananas, chocolate, eggplant, pineapples, plantains, red plums, tomatoes, and walnuts, can falsely elevate levels if ingested within 4 days of specimen collection.
- Severe gastrointestinal disturbance or diarrhea can interfere with test results.
- Failure to collect all the urine and store the specimen properly during the 24-hr test period invalidates the results.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.**

**Inform the patient that the test is used to diagnose carcinoid tumors.**

**Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.**

**Obtain a history of the patient’s endocrine, gastrointestinal, and immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.**

**Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.**

**Review the procedure with the patient.**

**Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device.**

**Address concerns about pain and explain to the patient that there should be no discomfort during the procedure.**

**Inform the patient that all urine collected over a 24-hr period must be saved; if a preservative has been added to the container, instruct the patient not to discard the preservative. Instruct the patient not to void directly into the container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom as a reminder to save all urine.**

**Instruct the patient to void all urine into the collection device, then pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.**

**Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.**

**There are no fluid restrictions, unless by medical direction.**

**Inform the patient that foods and medications listed under “Interfering**
Factors” should be restricted by medical direction for at least 4 days before specimen collection.

**INTRATEST:**
- Ensure that the patient has complied with dietary and medication restrictions; assure foods and medications listed under “Interfering Factors” have been restricted for at least 4 days prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

**Timed Specimen:**
- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started, and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage. Conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the specimen collection container’s label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results. Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume usual diet, as directed by the HCP. Consideration may be given to niacin supplementation and increased protein, if appropriate, for patients with abnormal findings. In some cases, the tumor may divert dietary tryptophan to serotonin, resulting in pellagra.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ALP, amino acid screen, antibodies gliadin, biopsy intestine, biopsy lung, calcium, cancer antigens, capsule endoscopy, chloride sweat, fecal fat, folate, and GTT.
- Refer to the Endocrine, Gastrointestinal, and Immune System tables at the back of the book for related tests by body system.
Hypersensitivity Pneumonitis Serology

SYNONYM/ACRONYM: Farmer’s lung disease serology, extrinsic allergic alveolitis.

SPECIMEN: Serum (2 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Immunodiffusion) Negative.

RESULT: CRITICAL VALUES: N/A

Increased in:
- Hypersensitivity Pneumonitis

Find and print out the full monograph at DavisPlus (davisplus.fadavis.com, keyword Van Leeuwen).

Hysterosalpingography

SYNONYM/ACRONYM: Uterography, uterosalpingography, hysterogram.

AREA OF APPLICATION: Uterus and fallopian tubes.

CONTRAST: Iodinated contrast medium.

DESCRIPTION: Hysterosalpingography is performed as part of an infertility study to identify anatomic abnormalities of the uterus or occlusion of the fallopian tubes. The procedure allows visualization of the uterine cavity, fallopian tubes, and peritubal area after the injection of contrast medium into the cervix. The contrast medium should flow through the uterine cavity, through the fallopian tubes, and into the peritoneal cavity, where it is absorbed if no obstruction exists. Passage of the contrast medium through the tubes may clear mucous plugs, straighten kinked tubes, or break up adhesions, thus restoring fertility. This procedure is also used to evaluate the fallopian tubes after tubal ligation and to evaluate the results of reconstructive surgery. Risks include uterine perforation, exposure to radiation, infection, allergic reaction to contrast medium, bleeding, and pulmonary embolism.

INDICATIONS:
- Confirm the presence of fistulas or adhesions
- Confirm tubal abnormalities such as adhesions and occlusions
- Confirm uterine abnormalities such as congenital malformation,

Access additional resources at davisplus.fadavis.com
traumatic injuries, or the presence of foreign bodies
- Detect bicornate uterus
- Evaluate adequacy of surgical tubal ligation and reconstructive surgery

RESULT:

Normal findings in:
- Contrast medium flowing freely into the fallopian tubes and from the uterus into the peritoneal cavity
- Normal position, shape, and size of the uterine cavity

Abnormal findings in:
- Bicornate uterus
- Developmental abnormalities
- Extraterine pregnancy
- Internal scarring
- Kinking of the fallopian tubes due to adhesions
- Partial or complete blockage of fallopian tube(s)
- Tumors
- Uterine cavity anomalies
- Uterine fistulas
- Uterine masses or foreign body
- Uterine fibroid tumors (leiomyomas)

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients who are in renal failure.
- Patients with menses, undiagnosed vaginal bleeding, or pelvic inflammatory disease.
- Young patients (17 yr and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.

Factors that may impair clear imaging:
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Insufficient injection of contrast medium
- Excessive traction during the test or tubal spasm, which may cause the appearance of a stricture in an otherwise normal fallopian tube

Other considerations:
- Excessive traction during the test may displace adhesions, making the fallopian tubes appear normal.
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow pretesting preparations may cause the procedure to be canceled or repeated.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel remaining in the room with the patient should wear a protective lead apron. Personnel working in the examination area should wear badges to record their level of radiation exposure.
Hysterosalpingography

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the uterus and fallopian tubes.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, and contrast mediums.
- Obtain a history of the patient’s reproductive and genitourinary systems and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent barium or other radiological contrast procedures. Ensure that barium studies were performed more than 4 days before the hysterosalpingography.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Explain to the patient that she may feel temporary sensations of nausea, dizziness, slow heartbeat, and menstrual-like cramping during the procedure, as well as shoulder pain from subphrenic irritation from the contrast medium as it spills into the peritoneal cavity. Inform the patient that the procedure is performed in a radiology department by a health care provider (HCP), with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during and after the procedure.
- Instruct the patient to take a laxative or a cathartic, as ordered, on the evening before the examination.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- There are no food, fluid or medication restrictions, unless by medical direction or department protocol.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

- Ensure the patient has complied with pretesting preparations prior to the procedure.
- Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Assess for completion of bowel preparation according to the institution’s procedure. Administer enemas or suppositories on the morning of the test, as ordered.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in a lithotomy position on the fluoroscopy table.
- A kidney, ureter, and bladder film is taken to ensure that no stool, gas, or barium will obscure visualization of the uterus and fallopian tubes.
- A speculum is inserted into the vagina, and contrast medium is introduced into the uterus through the cervix via a cannula, after which both fluoroscopic and radiographic images are taken.

Access additional resources at davisplus.fadavis.com
POST-TEST:

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual medications and activity, as directed by the HCP.
- Observe for delayed reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Inform the patient that a vaginal discharge is common and that it may be bloody, lasting 1 to 2 days after the test.
- Inform the patient that dizziness and cramping may follow this procedure, and that analgesia may be given if there is persistent cramping. Instruct the patient to contact the HCP in the event of severe cramping or profuse bleeding.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include CT abdomen, laparoscopy gynecological, MRI abdomen, US obstetric, US pelvis, and uterine fibroid embolization.
- Refer to the Genitourinary System table at the back of the book for related tests by body system.
**SYNONYM/ACRONYM:** IFE.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube. Urine (10 mL) from a random or timed collection in a clean plastic container.

**REFERENCE VALUE:** (Method: Immunoprecipitation combined with electrophoresis) Test results are interpreted by a pathologist. Normal placement and intensity of staining provide information about the immunoglobulin bands.

**DESCRIPTION:** Immunofixation electrophoresis (IFE) is a qualitative technique that provides a detailed separation of individual immunoglobulins according to their electrical charges. Abnormalities are revealed by changes produced in the individual bands, such as displacement, color, or absence of color. Urine IFE has replaced the Bence Jones screening test for light chains. IFE has replaced immunoelectrophoresis because it is more sensitive and easier to interpret.

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase immunoglobulin levels include asparaginase, cimetidine, and narcotics.
- Drugs that may decrease immunoglobulin levels include dextran, oral contraceptives, methylprednisolone (high doses), and phenytoin.
- Chemotherapy and radiation treatments may alter the width of the bands and make interpretation difficult.

**INDICATIONS:**
- Assist in the diagnosis of multiple myeloma and amyloidosis
- Assist in the diagnosis of suspected immunodeficiency
- Assist in the diagnosis of suspected immunoproliferative disorders, such as multiple myeloma and Waldenström's macroglobulinemia
- Identify biclonal or monoclonal gammopathies
- Identify cryoglobulinemia
- Monitor the effectiveness of chemotherapy or radiation therapy

**RESULT:**
See monograph titled “Immunoglobulins A, D, G, and M.”

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess the immune system with respect to the type and quantity of immunoglobulins in blood and urine.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
Note any recent procedures that can interfere with test results. Assess whether the patient received any vaccinations or immunizations within the last 6 mo or any blood or blood components within the last 6 wk.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device.

Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.

Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, date, and time of collection.

**Blood:**

Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

**Urine:**

**Clean-Catch Specimen:**

Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.

Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

**Blood or Urine:**

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in
Immunoglobulin E

SYNONYM/ACRONYM: IgE.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

DESCRIPTION: Immunoglobulin E (IgE) is an antibody whose primary response is to allergic reactions and parasitic infections. Most of the body’s IgE is bound to specialized tissue cells; little is available in the circulating blood. IgE binds to the membrane of special granulocytes called basophils in the circulating blood and mast cells in the tissues. Basophil and mast cell membranes have receptors for IgE. Mast cells are abundant in the skin and the tissues lining the respiratory and alimentary tracts. When IgE antibody becomes cross-linked with antigen/allergen, the release of histamine, heparin, and other chemicals from the granules in the cells is triggered. A sequence of events follows activation of IgE that affects smooth muscle contraction, vascular permeability, and inflammatory reactions. The inflammatory response allows proteins from the bloodstream to enter the tissues. Helminths (worm parasites) are especially susceptible to immunoglobulin-mediated cytotoxic chemicals. The inflammatory reaction...
proteins attract macrophages from the circulatory system and granulocytes, such as eosinophils, from circulation and bone marrow. Eosinophils also contain enzymes effective against the parasitic invaders.

**INDICATIONS:**
Assist in the evaluation of allergy and parasitic infection

**RESULT:**

*Increased in:*
Conditions involving allergic reactions or infections that stimulate production of IgE.
- Alcoholism *(Alcohol may play a role in the development of environmentally instigated IgE mediated hypersensitivity)*
- Allergy
- Asthma
- Bronchopulmonary aspergillosis
- Dermatitis
- Eczema
- Hay fever
- IgE myeloma
- Parasitic infestation
- Rhinitis
- Sinusitis
- Wiskott-Aldrich syndrome

*Decreased in:*
- Advanced carcinoma *(Generalized decrease in immune system response)*
- Agammaglobulinemia *(Related to decreased production)*
- Ataxia-telangiectasia *(Familial immunodeficiency disorder)*
- IgE deficiency

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may cause a decrease in IgE levels include phenytoin and tryptophan.
- Penicillin G has been associated with increased IgE levels in some patients with drug-induced acute interstitial nephritis.
- Normal IgE levels do not eliminate allergic disorders as a possible diagnosis.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess IgE levels in order to identify the presence of an allergic or inflammatory immune system response.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the
patient to breathe normally and to avoid unnecessary movement.

- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- **Nutritional considerations:** Increased IgE levels may be associated with allergy. Consideration should be given to diet if the patient has food allergies.

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the patient’s condition and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include allergen-specific IgE, alveolar/arterial gradient, biopsy intestine, biopsy liver, biopsy muscle, blood gases, carbon dioxide, complete blood count, eosinophil count, fecal analysis, hypersensitivity pneumonitis, lung perfusion scan, complete blood count, platelet count, PFT, and complete blood count, WBC count and differential.

- Refer to the Immune and Respiratory System tables at the back of the book for related tests by body system.

**DESCRIPTION:** Immunoglobulins A, D, E, G, and M are made by plasma cells in response to foreign particles. Immunoglobulins neutralize toxic substances, support phagocytosis, and destroy invading microorganisms. They are made up of heavy and light chains. Immunoglobulins produced by the proliferation of a single plasma cell (clone) are called monoclonal. Polyclonal increases result when multiple cell lines produce antibody. IgA is found mainly in secretions such as tears, saliva, and breast milk. It is believed to protect mucous membranes from viruses and bacteria. The function of IgD is not well understood. For details on IgE, see the monograph titled “Immunoglobulin E.” IgG is the predominant serum immunoglobulin and is important in long-term defense against disease. It is the only antibody that crosses the placenta. IgM is the largest immunoglobulin, and it is the first antibody to react to an antigenic stimulus. IgM also forms natural antibodies, such as ABO blood group antibodies. The presence of IgM in cord blood is an indication of congenital infection.

**INDICATIONS:**
- Assist in the diagnosis of multiple myeloma
- Evaluate humoral immunity status
- Monitor therapy for multiple myeloma
- IgA: Evaluate patients suspected of IgA deficiency prior to transfusion. Evaluate anaphylaxis associated with the transfusion of blood and blood products (anti-IgA antibodies may develop in patients with low levels of IgA, possibly resulting in anaphylaxis when donated blood is transfused)

**RESULT:**

**Increased in:**

**IgA:**
- Polyclonal:
  - Chronic liver disease *(Pathophysiology is not clear)*
Immunodeficiency states, such as Wiskott-Aldrich syndrome (Inherited condition of lymphocytes characterized by increased IgA and IgE)

Inflammatory bowel disease (IgG and/or IgA antibody positive for Saccharomyces cerevisiae with negative perinuclear-antineutrophil cytoplasmic antibody is indicative of Crohn’s disease)

Lower gastrointestinal (GI) cancer (Pathophysiology is not clear)

Rheumatoid arthritis (Pathophysiology is not clear)

• Monoclonal:
  IgA-type multiple myeloma (Related to excessive production by a single clone plasma cells)

IgD:
• Polyclonal: (Pathophysiology is unclear but increases are associated with increases in IgM)
  Certain liver diseases
  Chronic infections
  Connective tissue disorders

• Monoclonal:
  IgD-type multiple myeloma (Related to excessive production by a single clone plasma cells)

IgG:
Conditions that involve inflammation and/or development of an infection stimulate production of IgG.

• Polyclonal:
  Autoimmune diseases, such as systemic lupus erythematosus, rheumatoid arthritis, and Sjögren’s syndrome
  Chronic liver disease
  Chronic or recurrent infections
  Intrauterine devices (The IUD creates a localized inflammatory reaction that stimulates production of IgG)
  Sarcoidosis

• Monoclonal:
  IgG-type multiple myeloma (Related to excessive production by a single clone of plasma cells)

Leukemias
Lymphomas

IgM:
• Polyclonal: (Humoral response to infections and inflammation; both acute and chronic)
  Active sarcoidosis
  Chronic hepatocellular disease
  Collagen vascular disease
  Early response to bacterial or parasitic infection
  Hyper-IgM dysgammaglobulinemia
  Rheumatoid arthritis
  Variable in nephrogammatinemia
  Viral infection (hepatitis or mononucleosis)

• Monoclonal:
  Cold agglutinin hemolysis disease
  Malignant lymphoma
  Neoplasms (especially in GI tract)
  Reticulosis
  Waldenström’s macroglobulinemia (Related to excessive production by a single clone of plasma cells)

Decreased in:

IgA:
• Ataxia-telangiectasia
• Chronic sinopulmonary disease
• Genetic IgA deficiency

IgD:
• Genetic IgD deficiency
• Malignant melanoma of the skin
• Pre-eclampsia

IgG:
• Burns
• Genetic IgG deficiency
• Nephrotic syndrome
• Pregnancy

IgM:
• Burns
• Secondary IgM deficiency associated with IgG or IgA gammopathies

CRITICAL VALUES: N/A
INTERFERING FACTORS:

- Drugs that may increase immunoglobulin levels include asparaginase, cimetidine, and narcotics.
- Drugs that may decrease immunoglobulin levels include dextran, oral contraceptives, methylprednisolone (high doses), and phenytoin.
- Chemotherapy, immunosuppressive therapy, and radiation treatments decrease immunoglobulin levels.
- Specimens with macroglobulins, cryoglobulins, or cold agglutinins tested at cold temperatures may give falsely low values.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess the immune system with respect to the quantity of immunoglobulin levels present in the blood.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s GI, hematopoietic, immune, and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Note any recent procedures that can interfere with test results.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain to the patient that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include ALT, anion gap, ANA, bilirubin, biopsy bone, biopsy bone marrow, biopsy liver, biopsy lymph node, blood groups and antibodies, cold agglutinin, complete blood count, Coomb’s antiglobulin (direct and indirect), cryoglobulin, ESR, fibrinogen, IFE, quantitative immunoglobulin levels, GGT, LAP, liver and spleen scan, beta-2-microglobulin, platelet antibodies, protein total and fractions, RF, UA, and complete blood count, WBC count and differential.
- Refer to the Gastrointestinal, Hematopoietic, Immune, and Musculoskeletal System tables at the back of the book for related tests by body system.
### Immunosuppressants: Cyclosporine, Methotrexate

**SYNONYM/ACRONYM:** Cyclosporine (Sandimmune), methotrexate (MTX, amethopterin, Folex, Rheumatrex), methotrexate sodium (Mexate).

**SPECIMEN:** Whole blood (1 mL) collected in lavender-top tube for cyclosporine. Serum (1 mL) collected in a red-top tube for methotrexate.

<table>
<thead>
<tr>
<th>Immunosuppressant</th>
<th>Route of Administration</th>
<th>Recommended Collection Time</th>
</tr>
</thead>
<tbody>

*Dependent on therapeutic approach.

Access additional resources at davisplus.fadavis.com
DESCRIPTION: Cyclosporine is an immunosuppressive drug used in the management of organ rejection, especially rejection of heart, liver, and kidney transplants. Its most serious side effect is renal impairment or renal failure. Methotrexate is a highly toxic drug that causes cell death by disrupting DNA synthesis.

Many factors must be considered in effective dosing and monitoring of therapeutic drugs, including patient age, weight, interacting medications, electrolyte balance, protein levels, water balance, and conditions that affect absorption and excretion, as well as foods, herbals, vitamins, and minerals that can either potentiate or inhibit the intended target concentration.

INDICATIONS:

Cyclosporine:
• Assist in the management of treatments to prevent organ rejection
• Monitor for toxicity

Methotrexate:
• Monitor effectiveness of treatment of cancer and some autoimmune disorders
• Monitor for toxicity

RESULT:

<table>

</tr>
</tbody>
</table>

CRITICAL VALUES:

It is important to note the adverse effects of toxic and subtherapeutic levels. Care must be taken to investigate signs and symptoms of too little and too much medication. Note and immediately report to the health care provider (HCP) any critically increased values and related symptoms.

Cyclosporine: Greater than 400 ng/mL

Signs and symptoms of cyclosporine toxicity include increased severity of expected side effects, which include nausea, stomatitis, vomiting, anorexia, hypertension, infection, fluid retention, hypercalcemic metabolic acidosis, tremor, seizures, headache, and flushing. Possible interventions include close monitoring of blood levels to make dosing adjustments, inducing emesis (if orally ingested), performing gastric lavage (if orally ingested), withholding the drug, and initiating alternative therapy for a short time until the patient is stabilized.

Methotrexate: Greater than 5.00 micromol/L after 24 hr; greater than 0.50 micromol/L after 48 hr; greater than 0.05 micromol/L after 72 hr

Signs and symptoms of methotrexate toxicity include increased severity of expected side effects, which include nausea, stomatitis, vomiting, anorexia, bleeding, infection, bone marrow depression, and, over a prolonged period of use, hepatotoxicity. The effect of methotrexate on normal cells can be reversed by administration of 5-formyltetrahydrofolate (citrovorum or leucovorin). 5-Formyltetrahydrofolate allows higher doses of methotrexate to be given.

INTERFERING FACTORS:

• Numerous drugs interact with cyclosporine and either increase cyclosporine levels or increase the risk of toxicity. These drugs include acyclovir, aminoglycosides, amiodarone, amphotericin B, anabolic steroids, cephalosporins, cimetidine, danazol, erythromycin, furosemide, ketoconazole,
melphalan, methylprednisolone, miconazole, NSAIDs, oral contraceptives, and trimethoprim-sulfamethoxazole.

- Drugs that may decrease cyclosporine levels include carbamazepine, ethotoin, mephenytoin, phenobarbital, phenytoin, primidone, and rifampin.
- Drugs that may increase methotrexate levels or increase the risk of toxicity include NSAIDs, probenecid, salicylate, and sulfonamides.
- Antibiotics may decrease the absorption of methotrexate.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to monitor for therapeutic and toxic drug levels.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s genitourinary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Nutritional considerations: Patients taking immunosuppressant therapy tend to have decreased appetites due to the side effects of the medication. Instruct patients to consume a variety of foods within the basic food groups, maintain a healthy weight, be physically active, limit salt intake, limit alcohol intake, and be a nonsmoker.
- Recognize anxiety related to test results, and offer support. Patients receiving these drugs usually have conditions that can be intermittently moderately to severely debilitating, resulting in significant lifestyle changes. Educate the patient regarding access to counseling services, as appropriate.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Consider recommended collection time with regard to dosing schedule. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.
Infectious Mononucleosis Screen

**SYNONYM/ACRONYM:** Monospot, heterophil antibody test, IM serology.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Agglutination) Negative.

**DESCRIPTION:** Infectious mononucleosis is caused by the Epstein-Barr virus (EBV). The incubation period is 10 to 50 days, and the symptoms last 1 to 4 wk after the infection has fully developed. The hallmark of EBV infection is the presence of heterophil antibodies, also called Paul-Bunnell-Davidsohn antibodies, which are immunoglobulin M (IgM) antibodies that agglutinate sheep or horse red blood cells. The disease induces formation of abnormal lymphocytes in the lymph nodes; stimulates increased formation of heterophil antibodies; and is characterized by fever, cervical lymphadenopathy, tonsillopharyngitis, and hepatosplenomegaly. EBV is also thought to play a role in Burkitt’s lymphoma, nasopharyngeal carcinoma, and chronic fatigue syndrome. If the results of the heterophil antibody screening test are negative and infectious mononucleosis is highly suspected, EBV-specific serology should be requested.

**INDICATIONS:**
- Assist in confirming infectious mononucleosis

**RELATED MONOGRAPHS:**
- Related tests include BUN and creatinine.
- Refer to the Genitourinary and Immune System tables at the back of the book for related tests by body system.
RESULT:

Positive findings in:
Infectious mononucleosis

CRITICAL VALUES: N/A

INTERFERING FACTORS:

- False-positive results may occur in the presence of narcotic addiction, serum sickness, lymphomas, hepatitis, leukemia, cancer of the pancreas, and phenytoin therapy.
- A false-negative result may occur if treatment was begun before antibodies developed or if the test was done less than 6 days after exposure to the virus.

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of mononucleosis infection.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex. Obtain a history of exposure.
- Obtain a history of the patient’s hepatobiliary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent therapies that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Inform the patient that approximately 10% of all results are false-negative or false-positive. Inform the patient that signs and symptoms of infection include fever, chills, sore throat, enlarged lymph nodes, and fatigue. Self-care while the disease runs its course includes adequate fluid and nutritional intake along with sufficient rest. Activities that cause fatigue or stress should be avoided.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Advise the patient to refrain from direct contact with others because the disease is transmitted through saliva. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include complete blood count with peripheral blood smear evaluation.
- Refer to the Hepatobiliary and Immune System tables at the back of the book for related tests by body system.

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Radioimmunoassay)

**DESCRIPTION:** Insulin is secreted in response to elevated blood glucose, and its overall effect is to promote glucose use and energy storage. The insulin response test measures the rate of insulin secreted by the beta cells of the islets of Langerhans in the pancreas; it may be performed simultaneously with a 5-hr glucose tolerance test for hypoglycemia.

**INDICATIONS:**
- Assist in the diagnosis of early or developing non–insulin-dependent (type 2) diabetes, as indicated by excessive production of insulin in relation to blood glucose levels (best shown with glucose tolerance tests or 2-hr postprandial tests)
- Assist in the diagnosis of insulinoma, as indicated by sustained high levels of insulin and absence of blood glucose–related variations
- Confirm functional hypoglycemia, as indicated by circulating insulin levels appropriate to changing blood glucose levels
- Differentiate between insulin-resistant diabetes, in which insulin levels are high, and non–insulin-resistant diabetes, in which insulin levels are low
- Evaluate fasting hypoglycemia of unknown cause
- Evaluate postprandial hypoglycemia of unknown cause
- Evaluate uncontrolled insulin-dependent (type 1) diabetes

**RESULT:**

*Increased in:*
- Acromegaly *(Excess production of growth hormone increases insulin levels)*
- Alcohol use *(Stimulates insulin production)*
- Cushing’s syndrome *(Overproduction of cortisol increases insulin levels)*
- Excessive administration of insulin
- Insulin- and proinsulin-secreting tumors (insulinomas)
- Obesity *(Related to development of insulin resistance; body does not respond to insulin being produced)*
- Persistent hyperinsulinemic hypoglycemia *(Collection of hypoglycemic disorders of infants and children)*
- Reactive hypoglycemia in developing diabetes
- Severe liver disease

*Decreased in:*
- Beta cell failure *(Pancreatic beta cells produce insulin, therefore damage to these cells will decrease insulin levels)*
- Insulin-dependent diabetes *(Related to lack of endogenous insulin)*

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs and substances that may increase insulin levels include acetohexamide, alanine, albuterol, amino acids, beclomethasone, betamethasone, broxaterol, calcium gluconate, cannabis, chlorpropamide, cyclic AMP, glibornuride, glipizide, glitazepide, glucagon, glyburide, ibopamine, insulin, insulin-like growth factor–I, oral contraceptives, pancreozymin, prednisolone, prednisone, rifampin, salbutamol, terbutaline, tolazamide, tolbutamide, trichlormethiazide, and verapamil.
- Drugs that may decrease insulin levels include acarbose, asparaginase, calcitonin, cimetidine,
clofibrate, dexfenfluramine, diltiazem, doxazosin, enalapril, enprostil, ether, hydroxypropyl methylcellulose, insulin-like growth factor–I, metformin (Glucophage), niacin, nifedipine, nitrendipine, octreotide, phenytoin, propranolol, and psyllium.

- Administration of insulin or oral hypoglycemic agents within 8 hr of the test can lead to falsely elevated levels.
- Hemodialysis destroys insulin and affects test results.
- Recent radioactive scans or radiation can interfere with test results when radioimmunoassay is the test method.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the evaluation of fasting hypoglycemia.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals. Note the last time and dose of medication taken.
- Review the procedure with the patient. Inform the patient that multiple specimens may be required. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain to the patient that there may be some discomfort during the venipuncture.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- If a single sample is to be collected, the patient should have fasted and refrained, with medical direction, from taking insulin or other oral hypoglycemic agents for at least 8 hr before specimen collection. Protocols may vary from facility to facility.
- **Hypoglycemia:** Serial specimens for insulin levels are collected in conjunction with glucose levels after administration of a 100-g glucose load. The patient should be prepared as for a standard oral glucose tolerance test over a 5-hr period. Protocols may vary from facility to facility.
- There are no fluid restrictions, unless by medical direction.

**INTRATEST:**
- Ensure that the patient has complied with dietary and medication restrictions and other pretesting preparations; assure that food or medications have been restricted as instructed prior to the specific procedure’s protocol.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Instruct the patient to resume usual diet and medication, as directed by the HCP.

Nutritional considerations: Increased insulin levels may be associated with diabetes. The nutritional needs of each diabetic patient need to be determined individually (especially during pregnancy) by a health care professional trained in nutrition. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. There is no “diabetic diet”; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association.

Impaired glucose tolerance may be associated with diabetes. Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).

Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, as appropriate, that good glycemic control delays the onset of and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Diabetes Association (www.diabetes.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include ACTH, ALT, angiography adrenal, bilirubin, BUN, calcium, catecholamines, cholesterol (HDL, LDL, total), cortisol, C-peptide, DHEA, creatinine, fecal analysis, fecal fat, fructosamine, GGT, gastric emptying scan, glucagon, glucose, GTT, glycated hemoglobin, GH, HVA, insulin antibodies, ketones, lipoprotein electrophoresis, metanephrines, microalbumin, and myoglobin.

Refer to the Endocrine System table at the back of the book for related tests by body system.
Insulin Antibodies

SYNONYM/ACRONYM: N/A.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Radioimmunoassay) Less than 3%; includes binding of human, beef, and pork insulin to antibodies in patient’s serum.

DESCRIPTION: The most common anti-insulin antibody is immunoglobulin (Ig) G, but IgA, IgM, IgD, and IgE antibodies also have anti-insulin properties. These antibodies usually do not cause clinical problems, but they may complicate insulin assay testing. IgM is thought to participate in insulin resistance and IgE in insulin allergy. Improvements in the purity of animal insulin and increased use of human insulin have resulted in a significant decrease in the incidence of insulin antibody formation.

INDICATIONS:
- Assist in confirming insulin resistance
- Assist in determining if hypoglycemia is caused by insulin abuse
- Assist in determining insulin allergy

RESULT: Increased in:
- Factitious hypoglycemia (Assists in differentiating lack of response due to the presence of insulin antibodies from secretive self-administration of insulin)
- Insulin allergy or resistance (Antibodies bind to insulin and decrease amount of free insulin available for glucose metabolism)
- Polyendocrine autoimmune syndromes
- Steroid-induced diabetes (A side effect of treatment for systemic lupus erythematosus)

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS: Recent radioactive scans or radiation can interfere with test results when radioimmunoassay is the test method.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the prediction, diagnosis, and management of type I diabetes.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals. Note the last time and dose of medication taken.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Instruct the patient to resume usual diet and medication, as directed by the HCP.

Nutritional considerations: The nutritional needs of each diabetic patient need to be determined individually (especially during pregnancy) by a health care professional trained in nutrition. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. There is no “diabetic diet”; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association.

Impaired glucose tolerance may be associated with diabetes. Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).

Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, as appropriate, that good glycemic control delays the onset of and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Diabetes Association (www.diabetes.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include C-peptide, glucose, GTT, and insulin.

Refer to the Endocrine and Immune System tables at the back of the book for related tests by body system.
### Intraocular Muscle Function

**SYNONYM/ACRONYM:** IOM function.

**AREA OF APPLICATION:** Eyes.

**CONTRAST:** N/A.

**DESCRIPTION:** Evaluation of ocular motility is performed to detect and measure muscle imbalance in conditions classified as heterotropias or heterophorias. This evaluation is performed in a manner to assess fixation of each eye, alignment of both eyes in all directions, and the ability of both eyes to work together binocularly. Heterophorias are latent ocular deviations kept in check by the binocular power of fusion, and made intermittent by disrupting fusion. Heterotropias are conditions that manifest constant ocular deviations. The prefixes eso- (tendency for the eye to turn in), exo- (tendency for the eye to turn out), and hyper- (tendency for one eye to turn up) indicate the direction in which the affected eye moves spontaneously. Strabismus is the failure of both eyes to spontaneously fixate on the same object because of a muscular imbalance (crossed eyes). Amblyopia, or lazy eye, is a term used for loss of vision in one or both eyes that cannot be attributed to an organic pathological condition of the eye or optic nerve. There are six extraocular muscles in each eye whose movement is controlled by three nerves. The actions of the muscles vary depending on the position of the eye when they become innervated. The cover test is commonly used because it is reliable, easy to perform, and does not require special equipment. The cover test method is described in this monograph. Another method for evaluation of ocular muscle function is the corneal light reflex test. It is useful with patients who cannot cooperate for prism cover testing or for patients who have poor fixation.

**INDICATIONS:**
- Detection and evaluation of extraocular muscle imbalance

**RESULT:**
The examiner should determine the range of ocular movements in all gaze positions, usually to include up and out, in, down and out, up and in, down and in, and out. Limited movements in gaze position can be recorded semiquantitatively as −1 (minimal), −2 (moderate), −3 (severe), or −4 (total).

**Normal findings in:**
- Normal range of ocular movements in all gaze positions.

**Abnormal findings in:**
- Amblyopia
- Heterophorias
- Heterotropias
- Strabismus
INTRAOCULAR MUSCLE FUNCTION

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair the results of the examination:
- Inability of the patient to cooperate and remain still during the test because of age, significant pain, or mental status may interfere with the test results.
- Rubbing or squeezing the eyes may affect results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure evaluates extraocular muscle function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially latex.
- Obtain a history of the patient’s known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain and explain that no discomfort will be experienced during the test. Inform the patient that a health care provider (HCP) performs the test in a quiet room, and that to evaluate both eyes, the test can take 2 to 4 min.
- Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- One eye is tested at a time. The patient is given a fixation point, usually the testing personnel’s index finger. An object, such as a small toy, can be used to ensure fixation in pediatric patients. The patient is asked to follow the fixation point with his or her gaze in the direction the fixation point moves. When testing is completed, the procedure is repeated using the other eye. The procedure is performed at distance and near, first with and then without corrective lenses.

POST-TEST:
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss, anticipated loss of driving privileges, or the possibility of requiring corrective lenses (self-image).
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Educate the patient, as appropriate, that he or she may be referred for special therapy to correct the anomaly, which may include glasses, prisms, eye exercises, eye patches, or chemical patching with drugs that modify the focusing power of the eye. The patient and family should be educated that the chosen therapy involves a process of mental retraining. The mode of therapy in itself does not correct vision. It is the process by which the brain becomes readapted to accept, receive, and store visual images received by the eye that results in vision correction. Therefore,
the patient must be prepared to be alert, cooperative, and properly motivated. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include refraction and slit-lamp biomicroscopy.
- Refer to the Ocular System table at the back of the book for related tests by body system.

**Intraocular Pressure**

**SYNONYM/ACRONYM:** IOP.

**AREA OF APPLICATION:** Eyes.

**CONTRAST:** N/A.

**DESCRIPTION:** The intraocular pressure (IOP) of the eye depends on a number of factors. The two most significant are the amount of aqueous humor present in the eye and the circumstances by which it leaves the eye. Other physiological variables that affect IOP include respiration, pulse, and the degree of hydration of the body. Individual eyes respond to IOP differently. Some can tolerate high pressures (20 to 30 mm Hg), and some will incur optic nerve damage at lower pressures. With respiration, variations of up to 4 mm Hg in IOP can occur, and changes of 1 to 2 mm Hg occur with every pulsation of the central retinal artery. IOP is measured with a tonometer; normal values indicate the pressure at which no damage is done to the intraocular contents.

The rate of fluid leaving the eye, or its ability to leave the eye unimpeded, is the most important factor regulating IOP. There are three primary conditions that result in occlusion of the outflow channels for fluid. The most common condition is open-angle glaucoma, in which the diameter of the openings of the trabecular meshwork becomes narrowed, resulting in an increased IOP due to an increased resistance of fluid moving out of the eye. In secondary glaucoma, the trabecular meshwork becomes occluded by tumor cells, pigment, red blood cells in hyphema, or other material. Additionally, the obstructing material may cover parts of the meshwork itself, as with scar tissue or other types of adhesions that form after severe iritis, an angle-closure glaucoma attack, or a central retinal vein...
occlusion. The third condition impeding fluid outflow in the trabecular channels occurs with pupillary block, most commonly associated with primary angle-closure glaucoma. In eyes predisposed to this condition, dilation of the pupil causes the iris to fold up like an accordion against the narrow-angle structures of the eye. Fluid in the posterior chamber has difficulty circulating into the anterior chamber; therefore, pressure in the posterior chamber increases, causing the iris to bow forward and obstruct the outflow channels even more. Angle-closure attacks occur quite suddenly and therefore do not give the eye a chance to adjust itself to the sudden increase in pressure. The eye becomes very red, the cornea edematous (patient may report seeing halos), and the pupil fixed and dilated, accompanied by a complaint of moderate pain. Pupil dilation can be initiated by emotional arousal or fear, conditions in which the eye must adapt to darkness (movie theaters), or mydriatics. Angle-closure glaucoma is an ocular emergency resolved by a peripheral iridectomy to allow movement of fluid between the anterior and posterior chambers. This procedure constitutes removal of a portion of the peripheral iris either by surgery or by use of an argon or yttrium-aluminum-garnet (YAG) laser.

**INDICATIONS:**
- Diagnosis or ongoing monitoring of glaucoma
- Screening test included in a routine eye examination

**RESULT:**

**Normal findings in:**
- Normal IOP is between 13 and 22 mm Hg.

**Abnormal findings in:**
- Open-angle glaucoma
- Primary angle-closure glaucoma
- Secondary glaucoma

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Inability of the patient to remain still and cooperative during the test may interfere with the test results.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure measures intraocular pressure (IOP) of the eye.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to topical anesthetic eye drops.
- Obtain a history of the patient’s known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Explain that the patient will be requested to fixate the eyes during the procedure. Address concerns about
pain and explain that he or she may feel coldness or a slight sting when the anesthetic drops are instilled at the beginning of the procedure, but that no discomfort will be experienced during the test. Instruct the patient as to what should be expected with the use of the tonometer. The patient will experience less anxiety if he or she understands that the tonometer tip will touch the tear film and not the eye directly. Inform the patient that a health care provider (HCP) performs the test in a quiet, darkened room, and that to evaluate both eyes, the test can take 1 to 3 min.

Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRA-TEST:**

- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because any movement, such as coughing, breath holding, or wandering eye movements, produces unreliable results.
- Seat the patient comfortably. Instruct the patient to look at directed target while the eyes are examined.
- Instill ordered topical anesthetic in each eye, as ordered, and allow time for it to work. Topical anesthetic drops are placed in the eye with the patient looking up and the solution directed at the six o’clock position of the sclera (white of the eye) near the limbus (grey, semitransparent area of the eyeball where the cornea and sclera meet). Neither dropper nor bottle should touch the eyelashes.
- Instruct the patient to look straight ahead, keeping the eyes open and unblinking.
- A number of techniques are used to measure intraocular pressure.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss or anticipated loss of driving privileges. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information, if desired, for the Glaucoma Research Foundation (www.glaucoma.org).
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications, usually eye drops, that are intended to decrease intraocular pressure. Explain the

Intraocular pressure can be measured at the slit lamp or with a miniaturized, handheld applanation tonometer or an airpuff tonometer.

When the applanation tonometer is positioned on the patient’s cornea, the instrument’s headrest is placed against the patient’s forehead. The tonometer should be held at an angle with the handle slanted away from the patient’s nose. The tonometer tip should not touch the eyelids.

When the tip is properly aligned and in contact with the fluorescein-stained tear film, force is applied to the tip using an adjustment control to the desired endpoint. The tonometer is removed from the eye. The reading is taken a second time and, if the pressure is elevated, a third reading is taken. The procedure is repeated on the other eye.

With the airpuff tonometer, an air pump blows air onto the cornea, and the time it takes for the air puff to flatten the cornea is detected by infrared light and photoelectric cells. This time is directly related to the intraocular pressure.
Intravenous Pyelography

**SYNONYM/ACRONYM:** Excretory urography (EUG), intravenous urography (IVU, IUG), IVP.

**AREA OF APPLICATION:** Kidneys, ureters, bladder, and renal pelvis.

**CONTRAST:** IV radiopaque iodine-based contrast medium.

**DESCRIPTION:** Intravenous pyelography (IVP) is the most commonly performed test to determine urinary tract dysfunction or renal disease. IVP uses IV radiopaque contrast medium to visualize the kidneys, ureters, bladder, and renal pelvis. The contrast medium concentrates in the blood and is filtered out by the glomeruli; it passes out through the renal tubules and is concentrated in the urine. Renal function is reflected by the length of time it takes the contrast medium to appear and to be excreted by each kidney. A series of images is performed during a 30-min period to view passage of the contrast through the kidneys and ureters into the bladder. Tomography may be employed during the examination to permit the examination of an individual layer or plane of the organ that may be obscured by surrounding overlying structures.

**INDICATIONS:**
- Aid in the diagnosis of renovascular hypertension
- Evaluate the cause of blood in the urine
- Evaluate the effects of urinary system trauma

**RELATED MONOGRAPHS:**
- Related tests include fundus photography, gonioscopy, nerve fiber analysis, slit-lamp biomicroscopy, and visual field testing.
- Refer to the Ocular System table at the back of the book for related tests by body system.

** Importantly, adhering to the therapy regimen is crucial, especially since increased intraocular pressure may not present symptoms. Instruct the patient in both the ocular side effects and systemic reactions associated with the prescribed medication. Encourage them to review corresponding literature provided by a pharmacist. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.**
• Evaluate function of the kidneys, ureters, and bladder
• Evaluate known or suspected ureteral obstruction
• Evaluate the presence of renal, ureter, or bladder calculi
• Evaluate space-occupying lesions or congenital anomalies of the urinary system

RESULT:

Normal findings in:
• Normal size and shape of kidneys, ureters, and bladder
• Normal bladder and absence of masses or renal calculi, with prompt visualization of contrast medium through the urinary system

Abnormal findings in:
• Absence of a kidney (congenital malformation)
• Benign and malignant kidney tumors
• Bladder tumors
• Congenital renal or urinary tract abnormalities
• Glomerulonephritis
• Hydronephrosis
• Prostatic enlargement
• Pyelonephritis
• Renal cysts
• Renal hematomas
• Renal or ureteral calculi
• Soft-tissue masses
• Tumors of the collecting system

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
• Patients with bleeding disorders.
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
• Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
• Patients who are in renal failure.
• Patients with renal insufficiency, indicated by a BUN value greater than 40 mg/dL or creatinine value greater than 1.5 mg/dL, because contrast medium can complicate kidney function.
• Young patients (17 y.o. and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.
• Patients with multiple myeloma, who may experience decreased kidney function subsequent to administration of contrast medium.

Factors that may impair clear imaging:
• Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study.
• Retained barium from a previous radiological procedure.
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations:
• The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
• Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel remaining in the room with the patient should wear a protective lead apron. Personnel working in the examination area should wear badges to record their level of radiation exposure.

**Nursing Implications and Procedure**

**Pretest:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the kidneys, ureters, and bladder.
- Obtain a history of the patient’s complaints or symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast mediums.
- Obtain a history of the patient’s GI and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Ensure that the results of blood tests are obtained and recorded before the procedure, especially BUN and creatinine.
- Note any recent barium or other radiological contrast procedures. Ensure that barium studies were performed more than 4 days before the IVP.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

**Intratetest:**
- Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.
- If contrast media is scheduled to be used, patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a radiology department by a HCP, and takes approximately 30 to 60 min.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to take a laxative or a cathartic, as ordered, on the evening before the examination.
- Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

Ensure the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.
- Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Assess for completion of bowel preparation according to the institution’s procedure. Administer enemas...
or suppositories on the morning of the test, as ordered.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Place the patient in the supine position on an exam table.

A kidney, ureter, and bladder (KUB) or plain film is taken to ensure that no barium or stool obscures visualization of the urinary system.

Insert an IV line, if one is not already in place, and inject the contrast medium.

Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

Images are taken at 1, 5, 10, 15, 20, and 30 min following injection of the contrast medium into the urinary system. Instruct the patient to exhale deeply and to hold his or her breath while each image is taken.

Remove the needle or catheter and apply a pressure dressing over the puncture site.

Instruct the patient to void if a postvoiding exposure is required to visualize the empty bladder.

**POST-TEST:**

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.

Observe for delayed reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

Instruct the patient in the care and assessment of the injection site.

Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.

Monitor urinary output after the procedure. Decreased urine output may indicate impending renal failure.

Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Refer to the Genitourinary System table at the back of the book for related tests by body system.
**Intrinsic Factor Antibodies**

**SYNONYM/ACRONYM:** IF antibodies.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube. Plasma (1 mL) collected in a lavender-top (EDTA) tube is also acceptable.

**REFERENCE VALUE:** (Method: Radioimmunoassay) None detected.

**DESCRIPTION:** Intrinsic factor (IF) is produced by the parietal cells of the gastric mucosa and is required for the normal absorption of vitamin $B_{12}$. In some diseases, antibodies are produced that bind to the cobalamin-IF complex, prevent the complex from binding to ileum receptors, and prevent vitamin $B_{12}$ absorption. There are two types of antibodies: type 1, the more commonly present blocking antibody; and type 2, the binding antibody. The blocking antibody inhibits uptake of vitamin $B_{12}$ at the binding site of IF. Binding antibody combines with either free or complexed IF.

**INDICATIONS:**
- Assist in the diagnosis of pernicious anemia
- Evaluate patients with decreased vitamin $B_{12}$ levels

**RESULT:**
*Increased in:*
*Conditions that involve the production of these blocking and binding autoantibodies.*
- Megaloblastic anemia
- Pernicious anemia
- Some patients with hyperthyroidism

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Recent treatment with methotrexate or another folic acid antagonist can interfere with test results.
- Vitamin $B_{12}$ injected or ingested within 48 hr of the test invalidates results.
- Recent radioactive scans or radiation can interfere with test results when radioimmunoassay is the test method.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the investigation of suspected pernicious anemia.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
Obtain a history of the patient’s hematopoietic and gastrointestinal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Note any recent procedures that can interfere with test results. Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals. Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture. Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. There are no food or fluid restrictions, unless by medical direction. Administration of vitamin B₁₂ should be withheld within 48 hr before testing.

**INTRATEST:**
- Ensure that vitamin B₁₂ has been withheld within 48 hr before testing.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include antibodies antithyroglobulin and antithyroid peroxidase, biopsy bone marrow, complete blood count, complete blood count, RBC indices, folic acid, and vitamin B₁₂.
- Refer to the Hematopoietic and Gastrointestinal System tables at the back of the book for related tests by body system.

**Iron**

**SYNONYM/ACRONYM:** Fe.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** (Method: Spectrophotometry)
DESCRIPTION: Iron plays a principal role in erythropoiesis. Iron is necessary for the proliferation and maturation of red blood cells (RBCs) and is required for hemoglobin (Hgb) synthesis. Of the body's normal 4 g of iron, approximately 65% resides in Hgb and 3% in myoglobin. A small amount is also found in cellular enzymes that catalyze the oxidation and reduction of iron. The remainder of iron is stored in the liver, bone marrow, and spleen as ferritin or hemosiderin. Any iron present in the serum is in transit among the alimentary tract, the bone marrow, and available iron storage forms. Iron travels in the bloodstream bound to transferrin, a protein manufactured by the liver. Normally, iron enters the body by oral ingestion; only 10% is absorbed, but up to 20% can be absorbed in patients with iron-deficiency anemia. Unbound iron is highly toxic, but there is generally an excess of transferrin available to prevent the buildup of unbound iron in the circulation. Iron overload is as clinically significant as iron deficiency, especially in the accidental poisoning of children caused by excessive intake of iron-containing multivitamins.

INDICATIONS:
- Assist in the diagnosis of blood loss, as evidenced by decreased serum iron
- Assist in the diagnosis of hemochromatosis or other disorders of iron metabolism and storage
- Determine the differential diagnosis of anemia
- Determine the presence of disorders that involve diminished protein synthesis or defects in iron absorption
- Evaluate accidental iron poisoning
- Evaluate iron overload in dialysis patients or patients with transfusion-dependent anemias
- Evaluate thalassemia and sideroblastic anemia
- Monitor hematological responses during pregnancy, when serum iron is usually decreased
- Monitor response to treatment for anemia

RESULT:

**Increased in:**
- Acute iron poisoning (children) *(Related to excessive intake)*
- Acute leukemia
- Acute liver disease *(Possibly related to decrease in synthesis of iron storage proteins by damaged liver; iron accumulates and levels increase)*
- Aplastic anemia *(Increase is related to repeat blood transfusions)*
• Excessive iron therapy (Related to excessive intake)
• Hemochromatosis (Inherited disorder of iron overload; the iron is not excreted in proportion to the rate of accumulation)
• Hemolytic anemias (Iron is released from lysed RBCs)
• Lead toxicity (Lead can biologically mimic iron, displace it, and release it into circulation where its concentration increases)
• Nephritis (Related to decreased renal excretion; accumulation in blood)
• Pernicious anemias (PA) (Aclorhydria associated with PA prevents absorption of dietary iron and it accumulates in the blood)
• Sideroblastic anemias (Enzyme disorder prevents iron from being incorporated into Hgb and it accumulates in the blood)
• Thalassemia (Treatment for some types of thalassemia include blood transfusions, which can lead to iron overload)
• Transfusions (repeated)
• Vitamin B₆ deficiency (This vitamin is essential to Hgb formation; deficiency prevents iron from being incorporated into Hgb and it accumulates in the blood)

Decreased in:
• Acute and chronic infection (Iron is a nutrient for invading organisms)
• Carcinoma (Related to depletion of iron stores)
• Chronic blood loss (gastrointestinal, uterine) (Blood contains iron incorporated in Hgb)
• Hypothyroidism (Pathophysiology is unclear)
• Iron-deficiency anemia (Related to depletion of iron stores)

• Nephrosis (Anemia is common in people with kidney disease; fewer RBCs are made due to a deficiency of erythropoietin related to the damaged kidneys, blood can be lost in dialysis, and iron intake may be lower due to lack of appetite)
• Postoperative state
• Protein malnutrition (kwashiorkor) (Protein is required to form transport proteins, RBCs, and Hgb)

CRITICAL VALUES:

  Mild toxicity: greater than 350 mcg/dL
  Serious toxicity: greater than 400 mcg/dL
  Lethal: greater than 1000 mcg/dL

Note and immediately report to the health care provider (HCP) any critically increased values and related symptoms. Intervention may include chelation therapy by administration of deferoxamine mesylate (Desferal).

INTERFERING FACTORS:
• Drugs that may increase iron levels include blood transfusions, chemotherapy drugs, iron (intramuscular), iron dextran, iron-protein-succinylate, methimazole, methotrexate, oral contraceptives, and rifampin.
• Drugs that may decrease iron levels include acetylsalicylic acid, allopurinol, cholestyramine, corticotropin, cortisone, deferoxamine, and metformin.
• Gross hemolysis can interfere with test results.
• Failure to withhold iron-containing medications 24 hr before the test may falsely increase values.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used in the differential diagnosis of anemia.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s gastrointestinal and hematopoietic systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent therapies that can interfere with test results. Specimen collection should be delayed for several days after blood transfusion.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to fast for at least 12 hr before testing, and with medical direction, to refrain from taking iron-containing medicines before specimen collection. Protocols may vary from facility to facility.
- There are no fluid restrictions, unless by medical direction.

INTRATEST:
- Ensure that the patient has complied with dietary and medication restrictions; assure that food has been restricted for at least 12 hr prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

POST-TEST:
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the HCP.

Nutritional considerations: Educate the patient with abnormally elevated iron values, as appropriate, on the importance of reading food labels. Foods high in iron include meats (especially liver), eggs, grains, and green leafy vegetables. It is also important to explain that iron levels in foods can be increased if foods are cooked in cookware containing iron.

Nutritional considerations: Educate the patient with abnormal iron values that numerous factors affect the absorption of iron, enhancing or decreasing absorption regardless of the original content of the iron-containing dietary source. Patients must be educated to either increase or avoid intake of iron and iron-rich foods depending on their specific condition; for example a patient with hemochromatosis or acute pernicious anemia should be educated to avoid foods rich in iron. Consumption of large amounts of alcohol damages the intestine and allows increased absorption of iron. A high intake of calcium and ascorbic acid also increases iron absorption. Iron absorption after a meal is also increased by factors in meat, fish, and poultry. Iron absorption is decreased by the absence (gastric resection) or diminished presence (use of antacids).
Iron-Binding Capacity (Total), Transferrin, and Iron Saturation

**SYNONYM/ACRONYM:** TIBC, Fe Sat.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** (Method: Spectrophotometry for TIBC and nephelometry for transferrin)

<table>
<thead>
<tr>
<th>Test</th>
<th>Conventional Units</th>
<th>SI Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIBC</td>
<td>250–350 mcg/dL</td>
<td>45–63 micromol/L</td>
</tr>
<tr>
<td>Transferrin</td>
<td>200–380 mg/dL</td>
<td>2–3.8 g/L</td>
</tr>
<tr>
<td>Iron saturation</td>
<td>20–50%</td>
<td></td>
</tr>
</tbody>
</table>

TIBC = total iron-binding capacity.

**DESCRIPTION:** Iron plays a principal role in erythropoiesis. It is necessary for proliferation and maturation of red blood cells and for hemoglobin (Hgb) synthesis. Of the body’s normal 4 g of iron (less in women), about 65% is present in Hgb and about 3% in myoglobin. A small amount is also found in cellular enzymes that catalyze the oxidation and reduction of iron. The remainder of iron is stored in the liver, bone marrow, and spleen.
as ferritin or hemosiderin. Any iron present in the serum is in transit among the alimentary tract, the bone marrow, and available iron storage forms. Iron travels in the bloodstream bound to transport proteins. Transferrin is the major iron-transport protein, carrying 60% to 70% of the body’s iron. For this reason, total iron-binding capacity (TIBC) and transferrin are sometimes referred to interchangeably, even though other proteins carry iron and contribute to the TIBC. Unbound iron is highly toxic, but there is generally an excess of transferrin available to prevent the buildup of unbound iron in the circulation. The percentage of iron saturation is calculated by dividing the serum iron value by the TIBC value and multiplying by 100.

**INDICATIONS:**
- Assist in the diagnosis of iron-deficiency anemia
- Differentiate between iron-deficiency anemia and anemia secondary to chronic disease
- Monitor hematological response to therapy during pregnancy and iron-deficiency anemias
- Provide support for diagnosis of hemochromatosis or diseases of iron metabolism and storage

**RESULT:**

**Increased in:**
- Acute liver disease
- Hypochromic (iron-deficiency) anemias (Insufficient circulating iron levels to saturate binding sites)
- Late pregnancy

**Decreased in:**
- Chronic infections (Transferrin is a negative acute phase reactant protein and during periods of inflammation will demonstrate decreased levels)
- Cirrhosis (Transferrin is a negative acute phase reactant protein and during periods of inflammation will demonstrate decreased levels)
- Hemochromatosis (Occurs early in the disease as intestinal absorption of iron available for binding increases)
- Hemolytic anemias (Transferrin becomes saturated and the iron-binding capacity is significantly decreased)
- Neoplastic diseases (Transferrin is a negative acute phase reactant protein and during periods of inflammation will demonstrate decreased levels)
- Protein depletion (Transferrin contributes to the total protein concentration and will reflect a decrease in protein depletion)
- Renal disease (Transferrin is a negative acute phase reactant protein and during periods of inflammation will demonstrate decreased levels)
- Sideroblastic anemias (Transferrin becomes saturated and the iron-binding capacity is significantly decreased)
- Thalassemia (Transferrin becomes saturated and the iron-binding capacity is significantly decreased)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase TIBC levels include mestranol and oral contraceptives.
- Drugs that may decrease TIBC levels include asparaginase, chloramphenicol, corticotropin, cortisone, and testosterone.
**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used in the differential diagnosis of anemia.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include biopsy bone marrow, biopsy liver, complete blood count, complete blood count, RBC count, complete blood count, RBC indices, complete blood count, RBC morphology, complete blood count, WBC count and differential, erythropoietin, ferritin, folate, FEP, gallium scan, hemosiderin, lead, porphyrins, reticulocyte count, and vitamin B₁₂.
- Refer to the Hematopoietic System table at the back of the book for related tests by body system.
**SYNONYM/ACRONYM:** Synonyms/acronym: Ketone bodies, acetoacetate, acetone.

**SPECIMEN:** Serum (1 mL) collected from red- or tiger-top tube. Urine (5 mL), random or timed specimen, collected in a clean plastic collection container.

**REFERENCE VALUE:** (Method: Colorimetric nitroprusside reaction) Negative.

**DESCRIPTION:** Ketone bodies refer to the three intermediate products of metabolism: acetone, acetoacetic acid, and β-hydroxybutyrate. Even though β-hydroxybutyrate is not a ketone, it is usually listed with the ketone bodies. In healthy individuals, ketones are produced and completely metabolized by the liver so that measurable amounts are not normally present in serum. Ketones appear in the urine before a significant serum level is detectable. If the patient has excessive fat metabolism, ketones are found in blood and urine. Excessive fat metabolism may occur if the patient has impaired ability to metabolize carbohydrates, inadequate carbohydrate intake, inadequate insulin levels, excessive carbohydrate loss, or increased carbohydrate demand. A strongly positive acetone result without severe acidosis, accompanied by normal glucose, electrolyte, and bicarbonate levels, is strongly suggestive of isopropyl alcohol poisoning. A low-carbohydrate or high-fat diet may cause a positive acetone test. Ketosis in diabetics is usually accompanied by increased glucose and decreased bicarbonate and pH. Extremely elevated levels of ketone bodies can result in coma. This situation is particularly life-threatening in children younger than 10 y.o.

**INDICATIONS:**
- Assist in the diagnosis of starvation, stress, alcoholism, suspected isopropyl alcohol ingestion, glycogen storage disease, and other metabolic disorders
- Detect and monitor treatment of diabetic ketoacidosis
- Monitor the control of diabetes
- Screen for ketonuria due to acute illness or stress in nondiabetic patients
- Screen for ketonuria to assist in the assessment of inborn errors of metabolism
- Screen for ketonuria to assist in the diagnosis of suspected isopropyl alcohol poisoning

**RESULT:**

*Increased in:*

Ketones are generated in conditions that involve the metabolism of carbohydrates, fatty acids, and protein.

- Acidosis
- Branched-chain ketonuria
- Carbohydrate deficiency
- Eclampsia
- Fasting or starvation
- Gestational diabetes
- Glycogen storage diseases
- High-fat or high-protein diet
- Hyperglycemia
- Ketoacidosis of alcoholism and diabetes
- Illnesses with marked vomiting and diarrhea
- Isopropyl alcohol ingestion
- Methylmalonic aciduria
- Postanesthesia period
- Propionyl coenzyme A carboxylase deficiency
**Decreased in:** N/A

**CRITICAL VALUES:**

Strongly positive test results for glucose and ketones

Note and immediately report to the health care provider (HCP) strongly positive results in urine and related symptoms. An elevated level of ketone bodies is evidenced by fruity-smelling breathe, acidosis, ketonuria, and decreased level of consciousness. Administration of insulin and frequent blood glucose measurement may be indicated.

**INTERFERING FACTORS:**

- **Drugs that may cause an increase in serum ketone levels include:***
  - acetylsalicylic acid (if therapy results in acidosis, especially in children),
  - albuterol, fenfluramine, levodopa, nifedipine, and paraldehyde.
- **Drugs that may cause a decrease in serum ketone levels include:***
  - acetylsalicylic acid and valproic acid. Increases have been shown in hyperthyroid patients receiving propranolol and propylthiouracil.
- **Drugs that may increase urine ketone levels include:***
  - acetylsalicylic acid (if therapy results in acidosis, especially in children),
  - captopril, dimercaprol, ether, ifosfamide, insulin, levodopa, mesna, metformin, methyldopa, N-acetylcysteine, niacin, paraldehyde, penicillamine, phenazopyridine, phenolphthalein, phenolsulfonphthalein, pyrazinamide, streptozocin, sulfobromophthalein, and valproic acid.
- **Drugs that may decrease urine ketone levels include:***
  - acetylsalicylic acid and phenazopyridine.
- **Urine should be checked within 60 min of collection.
- **Bacterial contamination of urine can cause false-negative results.**
- **Failure to keep reagent strip container tightly closed can cause false-negative results.** Light and moisture affect the ability of the chemicals in the strip to perform as expected.
- **False-negative or weakly false-positive test results can be obtained when β-hydroxybutyrate is the predominating ketone body in cases of lactic acidosis.**

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is most commonly used to investigate diabetes as the cause of ketoacidosis.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that blood specimen collection takes approximately 5 to 10 min. The amount of time required to collect a urine specimen depends on the level of cooperation from the patient. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

- Observe standard precautions, and follow the general guidelines in Appendix A.

**Blood:**

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. Alternatively, a finger- or heel-stick method of specimen collection can be used.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

**Urine:**
Review the procedure with the patient. Explain to the patient how to collect a second-voided midstream (1) void, then drink a glass of water; and (2) wait 30 min, and then try to void again.

Instruct the patient to avoid excessive exercise and stress before specimen collection.

**Clean-Catch Specimen:**
Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.

Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

**Blood or Urine:**
Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

**Nutritional considerations:** Increased levels of ketone bodies may be associated with diabetes. Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).

**Nutritional considerations:** Increased levels of ketone bodies may be associated with poor carbohydrate intake; therefore, the body breaks down fat instead of carbohydrate for energy. Increasing carbohydrate intake in the patient’s diet reduces the levels of ketone bodies. Carbohydrates can be found in starches and sugars. Starch is a complex carbohydrate that can be found in foods such as grains (breads, cereals, pasta, rice) and starchy vegetables (corn, peas, potatoes). Sugar is a simple carbohydrate that can be found in natural foods (fruits and natural honey) and processed foods (desserts and candy).

Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, as appropriate, that good glycemic control delays the onset of and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Diabetes Association (www.diabetes.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process.
and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ACTH, angiography adrenal, anion gap, blood gases, BUN, calcium, catecholamines, cholesterol (HDL, LDL, total), cortisol, C-peptide, DHEA, electrolytes, fecal analysis, fecal fat, fructosamine, gastric emptying scan, GTT, glycated hemoglobin, HVA, insulin, insulin antibodies, lactic acid, lipoprotein electrophoresis, metanephrines, microalbumin, osmolality, phosphorus, and UA.
- Refer to the Endocrine System table at the back of the book for related tests by body system.

---

**Kidney, Ureter, and Bladder Study**

**SYNONYM/ACRONYM:** Flat plate of the abdomen, plain film of the abdomen, scout film, KUB.

**AREA OF APPLICATION:** Kidneys, ureters, bladder, and abdomen.

**CONTRAST:** None.

**DESCRIPTION:** A kidney, ureter, and bladder (KUB) x-ray examination provides information regarding the structure, size, and position of the abdominal organs; it also indicates whether there is any obstruction or abnormality of the abdomen caused by disease or congenital malformation. Calcifications of the renal calyces, renal pelvis, and any radiopaque calculi present in the urinary tract or surrounding organs may be visualized. Normal air and gas patterns are visualized within the intestinal tract. Perforation of the intestinal tract or an intestinal obstruction can be visualized on erect KUB images. KUB x-rays are among the first examinations done to diagnose intra-abdominal diseases such as intestinal obstruction, masses, tumors, ruptured organs, abnormal gas accumulation, and ascites.

**INDICATIONS:**
- Determine the cause of acute abdominal pain or palpable mass
- Evaluate the effects of lower abdominal trauma, such as internal hemorrhage
- Evaluate known or suspected intestinal obstructions
- Evaluate the presence of renal, ureter, or other organ calculi
- Evaluate the size, shape, and position of the liver, kidneys, and spleen
- Evaluate suspected abnormal fluid, air, or metallic objects in the abdomen

**RESULT:**

*Normal findings in:*
- Normal size and shape of kidneys
- Normal bladder, absence of masses and renal calculi, and no abnormal accumulation of air or fluid
Abnormal findings in:
• Abnormal accumulation of bowel gas
• Ascites
• Bladder distention
• Congenital renal anomaly
• Hydronephrosis
• Intestinal obstruction
• Organomegaly
• Renal calculi
• Renal hematomas
• Ruptured viscus
• Soft-tissue masses
• Trauma to liver, spleen, kidneys, and bladder
• Vascular calcification

CRITICAL VALUES:
• Bowel obstruction
• Ischemic bowel
• Visceral injury

Note and immediately report to the health care provider (HCP) positive results and related symptoms.

INTERFERING FACTORS:
This procedure is contraindicated for:
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
• Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
• Incorrect positioning of the patient, which may produce poor visualization of the area to be examined, for images done by portable equipment
• Retained barium from a previous radiological procedure

Other considerations:
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding patients younger than 17.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel remaining in the room with the patient should wear a protective lead apron. Personnel working in the examination area should wear badges to record their level of radiation exposure.

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses the status of the abdomen.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies and sensitivities to latex.
• Obtain a history of the patient’s gastrointestinal and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Address concerns about pain and explain that little to no pain is expected during the test, but there may be moments of discomfort. Inform the patient that the procedure is performed in the radiology department or at the bedside by a registered radiologic technologist, and takes approximately 5 to 15 min to complete.
Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- Instruct the patient to remove all metallic objects from the area to be examined.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

- Ensure the patient has removed all metallic objects from the area to be examined, prior to the procedure.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Place the patient on the table in a supine position with hands relaxed at the side.
- Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.

Observe standard precautions, and follow the general guidelines in Appendix A.

POST-TEST:

- A report will be sent to the requesting HCP, who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include angiography renal, calculus kidney stone panel, CT abdomen, CT pelvis, CT renal, IVP, and MRI abdomen, retrograde ureteropyelography, US abdomen, US kidney, US pelvis, and UA.
- Refer to the Gastrointestinal and Genitourinary System tables at the back of the book for related tests by body system.

Kleihauer-Betke Test

SYNONYM/ACRONYM: Fetal hemoglobin, hemoglobin F, acid elution slide test.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube. Freshly prepared blood smears are also acceptable. Cord blood may be requested for use as a positive control.

REFERENCE VALUE: (Method: Microscopic examination of treated and stained peripheral blood smear) Less than 1%.
DESCRIPTION: The Kleihauer-Betke test is used to determine the degree of fetal-maternal hemorrhage (FMH) and to help calculate the dosage of Rh immune globulin (RhIG); Rh-o(D) RhoGAM® IM or Rhophylac IM or IV to be given in some cases of Rh-negative mothers. A sample of maternal blood should be collected within one hour of delivery. A blood film of maternal red blood cells (RBCs) is prepared, treated with an acid buffer, and stained. The acid solution causes hemoglobin to be leached from the maternal cells, giving them a ghost-like appearance. Fetal cells containing hemoglobin F retain their hemoglobin and are stained bright red. Approximately 2000 cells are examined microscopically and counted. The ratio between maternal cells and fetal cells is determined. A percentage of fetal cells is reported. Enumeration of a total of 2000 cells is important to achieve the accuracy and precision to detect a FMH of 15 mL of fetal RBCs or 30 mL of fetal whole blood; the amount of FMH that corresponds to a 300-mcg dose of RhIG. Recommendations for initial RhIG doses range from 100–300 mcg to cover 10–30 mL fetal blood volumes. Many manufacturers recommend additional 50 mcg doses for each 2.5 mL of fetal blood. Calculation of RhIG dosage is based on the calculated size of FMH and should only be done after reviewing the information in the manufacturer’s package insert. The formula to calculate quantity of fetal bleed in mL of fetal blood is to multiply the percentage of fetal cells in maternal circulation by 50, based on the assumption that maternal blood volume is 5 liters. For example if percentage of fetal cells counted is 0.6%; then FMH = (0.6 × 50) = 30 mL. The formula to calculate FMH in relation to fetal blood cell volume is to multiply the percentage of fetal cells in maternal circulation by 2, based on the assumption that the hematocrit of fetal whole blood is 50%. For example if the quantity of fetal bleed is 30 mL of fetal whole blood; then FMH = (30/2) = 15 mL fetal RBCs. Postpartum RhIG should be given within 72 hr of delivery. The test can also be used to distinguish some forms of thalassemia from the hereditary persistence of fetal hemoglobin, but hemoglobin electrophoresis and flow cytometry methods are more commonly used for this purpose.

INDICATIONS:
• Assist in the diagnosis of certain types of anemia
• Calculating dosage of RhoGAM®
• Determine whether FMH was a potential cause of death in stillborn delivery
• Screening postpartum maternal blood for the presence of FMH

RESULT: Positive findings in:
• FMH (Related to leakage of fetal RBCs into maternal circulation)
• Hereditary persistence of fetal hemoglobin (The test does not differentiate fetal hemoglobin from neonate vs adult)

Negative findings in: N/A

CRITICAL VALUES: N/A
INTERFERING FACTORS:
Specimens must be obtained before transfusion.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to determine occurrence and extent of fetal-maternal bleed. It is also used to calculate Rh immune globulin dosage.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis. Sample must be less than 6 hr old.

POST-TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include amniotic fluid analysis, blood group and type, hemoglobin electrophoresis, and US obstetric.
- Refer to the Hematopoietic and Reproductive System tables at the back of the book for related tests by body system.
**SYNONYM/ACRONYM:** LDH and isos, LD and isos.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** (Method: Enzymatic [L to P] for lactate dehydrogenase, electrophoretic analysis for isoenzymes) Reference ranges are method dependent and may vary from laboratory to laboratory.

### Lactate Dehydrogenase

**RESULT:**

**Total LDH increased in:**
LDH is released from any damaged cell in which it is stored so conditions that affect the heart, liver, kidneys, red blood cells, skeletal muscle, or other tissue source and cause cellular destruction demonstrate elevated LDH levels.

- Carcinoma of the liver
- Chronic alcoholism
- Cirrhosis
- Congestive heart failure
- Hemolytic anemias
- Hypoxia
- Leukemias
- Megaloblastic and pernicious anemia
- MI or pulmonary infarction
- Musculoskeletal disease
- Obstructive jaundice
- Pancreatitis
- Renal disease (severe)
- Shock
- Viral hepatitis

**Total LDH decreased in:** N/A

**LDH Isoenzymes:**

- LDH$_1$ fraction increased over LDH$_2$ can be seen in acute MI, anemias (pernicious, hemolytic, acute sickle cell, megaloblastic, hemolytic), and acute renal cortical injury due to any cause. The LDH$_1$ fraction in particular is elevated in cases of germ cell tumors.

### Lactic Acid

**SYNONYM/ACRONYM:** Lactate.

**SPECIMEN:** Plasma (1 mL) collected in a gray-top (sodium fluoride) or green-top (lithium heparin) tube. Specimen should be transported tightly capped and in an ice slurry.

**REFERENCE VALUE:** (Method: Spectrophotometry/enzymatic analysis)

<table>

<tr>
<td>3–23 mg/dL</td>
<td>0.3–2.6 mmol/L</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Lactic acid (present in blood as lactate) is a by-product of carbohydrate metabolism. Normally metabolized in the liver, lactate concentration is based on the rate of production and metabolism. Levels increase during strenuous exercise, which results in insufficient oxygen delivery to the tissues. Pyruvate, the normal end product of glucose metabolism, is converted to lactate in emergency situations when energy is needed but there is insufficient oxygen in the system to favor the aerobic and customary energy cycle. When hypoxia or circulatory collapse increases production of lactate, or when the hepatic system does not metabolize lactate sufficiently, lactate levels become elevated. The lactic acid test can be performed in conjunction with pyruvic acid testing to monitor tissue oxygenation. Lactic acidosis can be differentiated from ketoacidosis by the absence of ketosis and grossly elevated glucose levels.

**INDICATIONS:**

- Assess tissue oxygenation
- Evaluate acidosis
RESULT:

Increased in:
The liver is the major organ responsible for the breakdown of lactic acid. Any condition affecting normal liver function may also reflect increased blood levels of lactic acid.

- Cardiac failure (Decreased blood flow and insufficient oxygen in tissues result in accumulation of lactic acid from anaerobic glycolysis)
- Diabetes (Inefficient aerobic glycolysis and decreased blood flow caused by diabetes result in accumulation of lactic acid from anaerobic glycolysis)
- Hemorrhage (Decreased blood circulation and insufficient oxygen in tissues result in accumulation of lactic acid from anaerobic glycolysis)
- Hepatic coma (Related to liver damage and decreased tissue oxygenation)
- Ingestion of large doses of alcohol or acetaminophen (Related to liver damage)
- Lactic acidosis (Related to strenuous exercise that results in accumulations in metabolic by-products of anaerobic breakdown of sugars for energy)
- Pulmonary embolism (Decreased blood flow and insufficient oxygen in tissues result in accumulation of lactic acid from anaerobic glycolysis)
- Pulmonary failure (Decreased blood flow and insufficient oxygen in tissues result in accumulation of lactic acid from anaerobic glycolysis)
- Reye’s syndrome (Related to liver damage)
- Shock (Decreased blood flow and insufficient oxygen in tissues result in accumulation of lactic acid from anaerobic glycolysis)
- Strenuous exercise (Related to lactic acidosis)

Decreased in: N/A

CRITICAL VALUES:

Greater than or equal to 31 mg/dL
Note and immediately report to the health care provider (HCP) any critically increased values and related symptoms. Observe the patient for signs and symptoms of elevated levels of lactate, such as Kussmaul’s breathing and increased pulse rate. In general, there is an inverse relationship between critically elevated lactate levels and survival.

INTERFERING FACTORS:

- Drugs that may increase lactate levels include albuterol, anticonvulsants (long-term use), epinephrine, IV glucose, isoniazid, lactose, metformin (Glucophage), oral contraceptives, sodium bicarbonate, and sorbitol.
- Falsely low lactate levels are obtained in samples with elevated levels of the enzyme lactate dehydrogenase because this enzyme reacts with the available lactate substrate.
- Using a tourniquet or instructing the patient to clench his or her fist during a venipuncture can cause elevated levels.
- Engaging in strenuous physical activity (i.e., activity in which blood flow and oxygen distribution cannot keep pace with increased energy needs) before specimen collection can cause an elevated result.
- Delay in transport of the specimen to the laboratory must be avoided. Specimens not processed by centrifugation in a tightly stoppered collection container within 15 min of collection should be rejected for analysis. It is preferable to transport specimens to the laboratory in an ice slurry to further retard cellular metabolism that might decay.
shift lactate levels in the sample before analysis.

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to investigate suspected lactic acidosis, most commonly caused by hypoperfusion.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular, endocrine, hepatobiliary, musculoskeletal, and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Instruct the patient to rest for 1 hr before specimen collection. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Instruct the patient to fast and to restrict fluids overnight. Instruct the patient not to ingest alcohol for 12 hr before the test. Protocols may vary from facility to facility.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no medication restrictions, unless by medical direction.
- Prepare an ice slurry in a cup or plastic bag to have on hand for immediate transport of the specimen to the laboratory.

**INTRATEST:**
- Ensure that the patient has complied with dietary restrictions and other pretesting preparations; assure that food and liquids have been restricted for at least 12 hours prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Instruct the patient not to clench and unclench fist immediately before or during specimen collection. Do not use a tourniquet. Perform a venipuncture. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage. Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet and fluids, as directed by the HCP.
- Nutritional considerations: Instruct patients to consume water when exercising. Dehydration may occur when the body loses water during exercise. Early signs of dehydration include dry mouth, thirst, and concentrated dark yellow urine. If replacement fluids are not consumed at this time, the patient may become moderately dehydrated and exhibit symptoms of extreme thirst, dry oral mucus membranes,
inability to produce tears, decreased urinary output, and light-headedness. Severe dehydration manifests as confusion, lethargy, vertigo, tachycardia, anuria, diaphoresis, and loss of consciousness. Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related laboratory tests include ALT, alveolar/arterial oxygen ratio, ammonia, analgesic and antipyretic drugs, anion gap, AST, biopsy liver, blood gases, CK, glucose, ketones, plethysmography, potassium, pulse oximetry, and sodium.
- Refer to the Cardiovascular, Endocrine, Hepatobiliary, Musculoskeletal, and Respiratory System tables at the back of the book for related tests by body system.

**SYNONYM/ACRONYM:** LTT.

**SPECIMEN:** Plasma (1 mL) collected in gray-top (fluoride/oxalate) tube.

**REFERENCE VALUE:** (Method: Spectrophotometry)

*Compared to fasting sample.

**DESCRIPTION:** Lactose is a disaccharide found in dairy products. When ingested, lactose is broken down in the intestine, by the sugar-splitting enzyme lactase, into glucose and galactose. When sufficient lactase is not available, intestinal bacteria metabolize the lactose, resulting in abdominal bloating, pain, flatus, and diarrhea. The lactose tolerance test screens for lactose intolerance by monitoring glucose levels after ingestion of a dose of lactose.

**INDICATIONS:**
Evaluate patients for suspected lactose intolerance

**RESULT:**

**Glucose levels increased in:**
Normal response

Access additional resources at davisplus.fadavis.com
Glucose levels decreased in:
Lactose intolerance (Lactase is insufficient to break down ingested lactose into glucose)

CRITICAL VALUES:
- Less than 40 mg/dL
- Greater than 400 mg/dL

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and symptoms.

Symptoms of decreased glucose levels include headache, confusion, hunger, irritability, nervousness, restlessness, sweating, and weakness. Possible interventions include oral or IV administration of glucose, IV or intramuscular injection of glucagon, and continuous glucose monitoring.

Symptoms of elevated glucose levels include abdominal pain, fatigue, muscle cramps, nausea, vomiting, polyuria, and thirst. Possible interventions include subcutaneous or IV injection of insulin with continuous glucose monitoring.

INTERFERING FACTORS:
- Numerous medications may alter glucose levels (see monograph titled “Glucose”).
- Delayed gastric emptying may decrease glucose levels.
- Smoking may falsely increase glucose levels.
- Failure to follow dietary and activity restrictions before the procedure may cause the procedure to be canceled or repeated.

Inform the patient that the test is used to evaluate lactose intolerance and other malabsorption disorders.

Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient’s gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Obtain the pediatric patient’s weight to calculate dose of lactose to be administered. Inform the patient that multiple samples will be collected over a 90-min interval. Inform the patient that each specimen collection takes approximately 5 to 10 min. Address concerns about pain related to the procedure. Inform the patient that the test may produce symptoms such as cramps and diarrhea. Instruct the patient not to smoke cigarettes or chew gum during the test. Explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Inform the patient that fasting for at least 12 hr before the test is required and that strenuous activity should also be avoided for at least 12 hr before the test. Protocols may vary from facility to facility.

There are no medication restrictions, unless by medical direction.

INTRATEST:

Ensure that the patient has complied with dietary and activity restrictions as well as other pretesting preparations; assure that food has been restricted for at least 12 hr prior to the procedure.

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Administer 50 g of lactose dissolved in a small amount of water to adults over a 5- to 10-min period. Pediatric
dosage is based on weight: 0.6 to 1.3 g lactose per kilogram of body weight for infants less than 12 mo old; 1.7 g lactose per kilogram of body weight for children 1 to 12 y.o. Record time of ingestion. Encourage the patient to drink one to two glasses of water.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in the appropriate tube or in a red pediatric Microtainer. Samples should be collected at baseline, 30, 45, 60, and 90 min. Record any symptoms the patient reports throughout the course of the test.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis. Glucose values change rapidly in an unprocessed, unpreserved specimen; therefore, if a Microtainer is used, each sample should be transported immediately after collection.

POST-TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient that resuming his or her usual diet may not be possible if lactose intolerance is identified. Educate patients on the importance of following the dietary advice of a nutritionist to ensure proper nutritional balance.

Nutritional considerations: Instruct the patient with lactose intolerance to avoid milk products and to carefully read labels on prepared products. Yogurt, which contains inactive lactase enzyme, may be ingested. The lactase in yogurt is activated by the temperature and pH of the duodenum and substitutes for the lack of endogenous lactase. Advise the patient that products such as Lactaid tablets or drops may allow ingestion of milk products without sequelae. Many lactose-free food products are now available in grocery stores.

Recognize anxiety related to test results, and be supportive of concerns related to a perceived change in lifestyle. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include d-xylose absorption, fecal analysis, and glucose.

Refer to the Gastrointestinal System table at the back of the book for related tests by body system.
Laparoscopy, Abdominal

SYNONYM/ACRONYM: Abdominal peritoneoscopy.

AREA OF APPLICATION: Pelvis.

CONTRAST: Carbon dioxide (CO₂).

DESCRIPTION: Abdominal or gastrointestinal (GI) laparoscopy provides direct visualization of the liver, gallbladder, spleen, and stomach after insufflation of carbon dioxide (CO₂). In this procedure, a rigid laparoscope is introduced into the body cavity through a 1- to 2-cm abdominal incision. The endoscope has a microscope to allow visualization of the organs, and it can be used to insert instruments for performing certain procedures, such as biopsy and tumor resection. Under general anesthesia, the peritoneal cavity is inflated with 2 to 3 L of CO₂. The gas distends the abdominal wall so that the instruments can be inserted safely. Advantages of this procedure compared to an open laparotomy include reduced pain, reduced length of stay at the hospital or surgical center, and reduced time off from work.

INDICATIONS:
- Assist in performing surgical procedures such as cholecystectomy, appendectomy, hernia repair, hiatal hernia repair, and bowel resection
- Detect cirrhosis of the liver
- Detect pancreatic disorders
- Evaluate abdominal pain or abdominal mass of unknown origin
- Evaluate abdominal trauma in an emergency
- Evaluate and treat appendicitis
- Evaluate the extent of splenomegaly due to portal hypertension
- Evaluate jaundice of unknown origin
- Obtain biopsy specimens of benign or cancerous tumors
- Stage neoplastic disorders such as lymphomas, Hodgkin’s disease, and hepatic carcinoma

RESULT:
Normal findings in:
- Normal appearance of the liver, spleen, gallbladder, pancreas, and other abdominal contents

Abnormal findings in:
- Abdominal adhesions
- Appendicitis
- Ascites
- Cancer of any of the organs
- Cirrhosis of the liver
- Gangrenous gallbladder
- Intra-abdominal bleeding
- Portal hypertension
- Splenomegaly

CRITICAL VALUES:
- Appendicitis

Note and immediately report to the health care provider (HCP) positive results and related symptoms.

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients who are pregnant or suspected of being pregnant,
unless the potential benefits of the procedure far outweigh the risk of radiation exposure to the fetus.

- Patients with bleeding disorders, especially those associated with uremia and cytotoxic chemotherapy.
- Patients with cardiac conditions or dysrhythmias.
- Patients with advanced respiratory or cardiovascular disease.
- Patients with intestinal obstruction, abdominal mass, abdominal hernia, or suspected intra-abdominal hemorrhage.
- Patients with a history of peritonitis or multiple abdominal operations causing dense adhesions.

**Factors that may impair clear visualization:**

- Gas or feces in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.

**Other considerations:**

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Patients who are in a hypoxemic or hypercapnic state will require continuous oxygen administration.
- Patients with acute infection or advanced malignancy involving the abdominal wall are at increased risk because organisms may be introduced into the normally sterile peritoneal cavity.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the abdominal organs.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
- Obtain a history of the patient’s GI, genitourinary, reproductive, and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Ensure that this procedure is performed before any barium studies.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- Note the last time and dose of medication taken.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a surgery department, by a health care provider (HCP), with support staff, and takes approximately 30 to 60 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is

Access additional resources at davisplus.fadavis.com
Place the patient on the laparoscopy table. If general anesthesia is to be used, it is administered at this time. Place the patient in a modified lithotomy position with the head tilted downward. Cleanse the abdomen with an antiseptic solution, and drape and catheterize the patient, if ordered.

The HCP identifies the site for the scope insertion, and administers local anesthesia if that is to be used. After deeper layers are anesthetized, a pneumoperitoneum needle is placed between the visceral and parietal peritoneum.

CO₂ is insufflated through the pneumoperitoneum needle to separate the abdominal wall from the viscera and to aid in visualization of the abdominal structures. The pneumoperitoneum needle is removed, and the trocar and laparoscope are inserted through the incision.

After the examination, collection of tissue samples, and performance of therapeutic procedures, the scope is withdrawn. All possible CO₂ is evacuated via the trocar, which is then removed. The skin incision is closed with sutures, clips, or sterile strips, and a small dressing or adhesive strip is applied.

POST-TEST:

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, and medication, as directed by the HCP.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

Instruct the patient to restrict activity for 2 to 7 days after the procedure.

If indicated, inform the patient of a follow-up appointment for the removal of sutures.

Inform the patient that shoulder discomfort may be experienced for 1 or 2 days after the procedure as a result of abdominal distention caused by...
LAPAROSCOPY, GYNECOLOGIC

insufflation of CO₂ into the abdomen, and that mild analgesics and cold compresses, as ordered, can be used to relieve the discomfort.

Emphasize that any persistent shoulder pain, abdominal pain, vaginal bleeding, fever, redness, or swelling of the incisional area must be reported to the HCP immediately.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include amylase, barium swallow, biopsy bone marrow, complete blood count, complete blood count, WBC count and differential, CT abdomen, CT biliary tract and liver, CT pancreas, CRP, ESR, gallium scan, hepatobiliary scan, KUB, lipase, liver and spleen scan, lymphangiogram, MRI abdomen, MRI pelvis, peritoneal fluid analysis, US abdomen, and US pelvis.

Refer to the Gastrointestinal, Genitourinary, Reproductive, and Hepatobiliary System tables in the back of the book for related tests by body system.

SYNONYM/ACRONYM: Gynecologic pelviscopy, gynecologic laparoscopy, pelvic endoscopy, peritoneoscopy.

AREA OF APPLICATION: Pelvis.

CONTRAST: Carbon dioxide (CO₂).

DESCRIPTION: Gynecologic laparoscopy provides direct visualization of the internal pelvic contents, including the ovaries, fallopian tubes, and uterus, after insufflation of carbon dioxide (CO₂). It is done to diagnose and treat pelvic organ disorders, as well as to perform surgical procedures on the organs. In this procedure, a rigid laparoscope is introduced into the body cavity through a 1- to 2-cm periumbilical incision. The endoscope has a microscope to allow visualization of the organs, and it can be used to insert instruments for performing certain procedures, such as biopsy and tumor resection. Under general or local anesthesia, the peritoneal cavity is inflated with 2 to 3 L of CO₂. The gas distends the abdominal wall so that the instruments can be inserted safely. Advantages of this procedure compared to an open laparotomy include reduced pain, reduced length of stay at the hospital or surgical center, and reduced time off from work.

Laparoscopy, Gynecologic
INDICATIONS:
- Detect ectopic pregnancy and determine the need for surgery
- Detect pelvic inflammatory disease or abscess
- Detect uterine fibroids, ovarian cysts, and uterine malformations (ovarian cysts may be aspirated during the procedure)
- Evaluate amenorrhea and infertility
- Evaluate fallopian tubes and anatomic defects to determine the cause of infertility
- Evaluate known or suspected endometriosis, salpingitis, and hydrosalpinx
- Evaluate pelvic pain or masses of unknown cause
- Evaluate reproductive organs after therapy for infertility
- Obtain biopsy specimens to confirm suspected pelvic malignancies or metastasis
- Perform tubal sterilization and ovarian biopsy
- Perform vaginal hysterectomy
- Remove adhesions or foreign bodies such as intrauterine devices
- Treat endometriosis through electrocautery or laser vaporization

RESULT:
Normal findings in:
- Normal appearance of uterus, ovaries, fallopian tubes, and other pelvic contents

Abnormal findings in:
- Ectopic pregnancy
- Endometriosis
- Ovarian cyst
- Ovarian tumor
- Pelvic adhesions
- Pelvic inflammatory disease
- Pelvic tumor
- Salpingitis
- Uterine fibroids

CRITICAL VALUES:
- Ectopic pregnancy
- Foreign body
- Tumor with significant mass effect

Note and immediately report to the health care provider (HCP) positive results and related symptoms.

INTERFERING FACTORS:
This procedure is contraindicated for:
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
- Patients with bleeding disorders, especially those associated with uremia and cytotoxic chemotherapy
- Patients with cardiac conditions or dysrhythmias
- Patients with advanced respiratory or cardiovascular disease
- Patients with intestinal obstruction, abdominal mass, abdominal hernia, or suspected intra-abdominal hemorrhage

Factors that may impair clear visualization:
- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

Other considerations:
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
• Patients who are in a hypoxemic or hypercapnic state will require continuous oxygen administration.
• Patients with acute infection or advanced malignancy involving the abdominal wall are at increased risk because organisms may be introduced into the normally sterile peritoneal cavity.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the abdominal and pelvic organs.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
- Obtain a history of the patient’s GI, genitourinary, reproductive, and hepato-biliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Ensure that this procedure is performed before any barium studies.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a history of the patient’s GI, genitourinary, reproductive, and hepato-biliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Ensure that this procedure is performed before any barium studies.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

**INTRATEST:**
- Ensure that the patient has complied with dietary, fluid, and medication restrictions for at least 8 hr prior to the procedure.
- Ensure the patient has removed all external metallic objects from the area to be examined.
- Ensure that nonallergy to anesthesia is confirmed before the procedure is performed under general anesthesia.
- Assess for completion of bowel preparation according to the institution’s procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Moments of discomfort. Inform the patient that the procedure is performed in a surgery department, by a health care provider (HCP) and support staff and takes approximately 30 to 60 minutes.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.

Inform the patient that a laxative and cleansing enema may be needed the day before the procedure, with cleansing enemas on the morning of the procedure, depending on the institution’s policy.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.

Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.
Obtain and record baseline vital signs.

Observe standard precautions, and follow the general guidelines in Appendix A.

Insert an IV line or venous access device at a low “keep open” rate.

Administer medications, as ordered, to reduce discomfort and to promote relaxation and sedation.

Place the patient on the laparoscopy table. If general anesthesia is to be used, it is administered at this time.

Place the patient in a modified lithotomy position with the head tilted downward. Cleanse the abdomen with an antiseptic solution, and drape and catheterize the patient, if ordered.

The HCP identifies the site for the scope insertion, and administers local anesthesia if that is to be used. After deeper layers are anesthetized, a pneumoperitoneum needle is placed between the visceral and parietal peritoneum.

CO₂ is insufflated through the pneumoperitoneum needle to separate the abdominal wall from the viscera and to aid in visualization of the abdominal structures. The pneumoperitoneum needle is removed, and the trocar and laparoscope are inserted through the incision.

The HCP inserts a uterine manipulator through the vagina and cervix and into the uterus so that the uterus, fallopian tubes, and ovaries can be moved to permit better visualization.

After the examination, collection of tissue samples, and performance of therapeutic procedures (e.g., tubal ligation), the scope is withdrawn. All possible CO₂ is evacuated via the trocar, which is then removed. The skin incision is closed with sutures, clips, or sterile strips, and a small dressing or adhesive strip is applied. After the perineum is cleansed, the uterine manipulator is removed and a sterile pad applied.

**POST-TEST:**

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, and medication, as directed by the HCP.

Monitor vital signs and neurological status every 15 minutes for 1 hour, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

Instruct the patient to restrict activity for 2 to 7 days after the procedure.

If indicated, inform the patient of a follow-up appointment for the removal of sutures.

Inform the patient that shoulder discomfort may be experienced for 1 or 2 days after the procedure as a result of abdominal distention caused by insufflation of CO₂ into the abdomen, and that mild analgesics and cold compresses, as ordered, can be used to relieve the discomfort.

Emphasize that any persistent shoulder pain, abdominal pain, vaginal bleeding, fever, redness, or swelling of the incisional area must be reported to the HCP immediately.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include cancer antigens, Chlamydia group antibody, CT abdomen, CT pelvis, HCG, MRI pelvis, PAP smear, progesterone, US pelvis, and uterine fibroid embolization.

Refer to the Gastrointestinal, Genitourinary, Reproductive, and Hepatobiliary System tables in the back of the book for related tests by body system.

OSHA = Occupational Safety and Health Administration.

**DESCRIPTION:** Lead is a heavy metal and trace element. It is absorbed through the respiratory and gastrointestinal systems. It can also be transported from mother to fetus through the placenta. When there is frequent exposure to lead-containing items (e.g., paint, batteries, gasoline, pottery, bullets, printing materials) or occupations (mining, automobile, printing, and
welding industries), many organs of the body are affected. Lead poisoning can cause severe behavioral and neurological effects. The blood test is considered the best indicator of lead poisoning, and confirmation is made by the lead mobilization test performed on a 24-hr urine specimen.

**INDICATIONS:**
Assist in the diagnosis and treatment of lead poisoning

**RESULT:**

**Increased in:**

**Heme synthesis involves the conversion of δ-amino levulinic acid to porphobilinogen.** Lead interferes with the enzyme that is responsible for this critical step in heme synthesis, amino levulinic acid dehydrase.

- Anemia of lead intoxication
- Lead encephalopathy
- Metal poisoning

**Decreased in:** N/A

**CRITICAL VALUES:**

Levels greater than 30 mcg/dL indicate significant exposure.

Levels greater than 60 mcg/dL require chelation therapy.

Note and immediately report to the health care provider (HCP) any critically increased values and related symptoms.

**INTERFERING FACTORS:**

Contamination of the collection site and/or specimen with lead in dust can be avoided by taking special care to have the surfaces surrounding the collection location cleaned. Extra care should also be used to avoid contamination during the actual venipuncture.
Lecithin/Sphingomyelin Ratio

**SYNONYM/ACRONYM:** L/S ratio.

**SPECIMEN:** Amniotic fluid (10 mL) collected in a sterile, brown glass or plastic tube or bottle protected from light.

**REFERENCE VALUE:** (Method: Thin-layer chromatography)
- **Mature (nondiabetic):** Greater than 2:1 in the presence of phosphatidyl glycerol
- **Borderline:** 1.5 to 1.9:1
- **Immature:** Less than 1.5:1

**DESCRIPTION:** Respiratory distress syndrome (RDS) is the most common problem encountered in the care of premature infants. RDS, also called hyaline membrane disease, results from a deficiency of phospholipid lung surfactants. The phospholipids in surfactant are produced by specialized alveolar cells and stored in granular lamellar bodies in the lung. In normally developed lungs, surfactant coats the surface of the alveoli. Surfactant reduces the surface tension of the alveolar wall during breathing. When there is an insufficient quantity of surfactant, the alveoli are unable to expand normally and gas exchange is inhibited. Amniocentesis, a procedure by which fluid is removed from the amniotic sac, is used to assess fetal lung maturity.

Lecithin is the primary surfactant phospholipid, and it is a stabilizing factor for the alveoli. It is produced at a low but constant rate until the 35th wk of gestation, after which its production sharply increases. Sphingomyelin, another phospholipid component of surfactant, is also produced at

**PERFORMED TO EVALUATE OR MONITOR PROGRESSION OF THE DISEASE PROCESS AND DETERMINE THE NEED FOR A CHANGE IN THERAPY. EVALUATE TEST RESULTS IN RELATION TO THE PATIENT’S SYMPTOMS AND OTHER TESTS PERFORMED.**

**RELATED MONOGRAPHS:**
- Related tests include δ-aminolevulinic acid, complete blood count, complete blood count, RBC morphology, erythrocyte protoporphyrin, and urine porphyrins.
- Refer to the Hematopoietic and Therapeutic/Toxicology tables at the back of the book for related tests by body system.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.
a constant rate after the 26th wk of gestation. Before the 35th wk, the lecithin/sphingomyelin (L/S) ratio is usually less than 1.6:1. The ratio increases to 2.0 or greater when the rate of lecithin production increases after the 35th wk of gestation. Other phospholipids, such as phosphatidyl glycerol (PG) and phosphatidyl inositol (PI), increase over time in amniotic fluid as well. The presence of PG indicates that the fetus is within 2 to 6 wk of lung maturity (i.e., at full term). Simultaneous measurement of PG with the L/S ratio improves diagnostic accuracy. Production of phospholipid surfactant is delayed in diabetic mothers. Therefore, caution must be used when interpreting the results obtained from a diabetic patient, and a higher ratio is expected to predict maturity.

**INDICATIONS:**
- Assist in the evaluation of fetal lung maturity
- Determine the optimal time for obstetric intervention in cases of threatened fetal survival caused by stresses related to maternal diabetes, toxemia, hemolytic diseases of the newborn, or postmaturity
- Identify fetuses at risk of developing RDS

**RESULT:**

**Increased in:**
- Conditions that increase production of surfactant
  - Hypertension
  - Intrauterine growth retardation
  - Malnutrition
  - Maternal diabetes
  - Placenta previa
  - Placental infarction
  - Premature rupture of the membranes

**Decreased in:**
- Conditions that decrease production of surfactant
  - Advanced maternal age
  - Immature fetal lungs
  - Multiple gestation
  - Polyhydramnios

**CRITICAL VALUES:**
An L/S ratio less than 1.5:1 is predictive of RDS at the time of delivery. Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms. Infants known to be at risk for RDS can be treated with surfactant by intratracheal administration at birth.

**INTERFERING FACTORS:**
- Fetal blood falsely elevates the L/S ratio.
- Exposing the specimen to light may cause falsely decreased values.
- There is some risk to having an amniocentesis performed, and this should be weighed against the need to obtain the desired diagnostic information. A small percentage (0.5%) of patients have experienced complications including premature rupture of the membranes, premature labor, spontaneous abortion, and stillbirth.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is primarily used to obtain an estimate of fetal lung maturity.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
Obtain a history of the patient’s reproductive and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Include any family history of genetic disorders such as cystic fibrosis, Duchenne muscular dystrophy, hemophilia, sickle cell disease, Tay-Sachs disease, thalassemia, and trisomy 21. Obtain maternal Rh type. If Rh-negative, check for prior sensitization. A standard RhoGAM dose is indicated after amniocentesis; repeat doses should be considered if repeated amniocentesis is performed.

Record the date of the last menstrual period, and determine that the pregnancy is in the third trimester between the 28th and 40th wk.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Warn the patient that normal results do not guarantee a normal fetus. Assure the patient that precautions to avoid injury to the fetus will be taken by localizing the fetus with ultrasound. Address concerns about pain and explain that during the transabdominal procedure, any discomfort with a needle biopsy will be minimized with local anesthetics. Patients who are at 20 wk gestation or beyond should void before the test, because an empty bladder is less likely to be accidentally punctured during specimen collection. Encourage relaxation and controlled breathing during the procedure to aid in reducing any mild discomfort. Inform the patient that specimen collection is performed by a HCP specializing in this procedure and usually takes approximately 20 to 30 min to complete.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

Ensure that the patient has voided before the procedure if gestation is 21 wk or more.

Have emergency equipment readily available.

Have patient remove clothes below the waist. Assist the patient to a supine position on the exam table with abdomen exposed. Drape the patient’s legs, leaving the abdomen exposed. Raise her head or legs slightly to promote comfort and to relax abdominal muscles. If the uterus is large, place a pillow or rolled blanket under the patient’s right side to prevent hypertension caused by great-vessel compression.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.

Record maternal and fetal baseline vital signs and continue to monitor throughout the procedure. Monitor for uterine contractions. Monitor fetal vital signs using ultrasound. Protocols may vary from facility to facility.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.

Assess the position of the amniotic fluid, fetus, and placenta using ultrasound.

Assemble the necessary equipment, including an amniocentesis tray with solution for skin preparation, local anesthetic, 10- or 20-mL syringe, needles of various sizes (including a 22-gauge, 5-in. spinal needle), sterile drapes, sterile gloves, and foil-covered or amber specimen collection containers.

Cleanse suprapubic area with an antiseptic solution and protect with sterile drapes. A local anesthetic is injected. Explain that this may cause a stinging sensation.

A 22-gauge, 5-in. spinal needle is inserted through the abdominal and
After the fluid is collected and the needle withdrawn, apply slight pressure to the site. Apply a sterile adhesive bandage to the site.

Monitor the patient for complications related to the procedure (e.g., premature labor, allergic reaction, anaphylaxis).

Place samples in properly labeled specimen container and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Fetal heart rate and maternal vital signs (i.e., heart rate, blood pressure, pulse, and respiration) must be compared to baseline values and closely monitored every 15 min for 30 to 60 min after the amniocentesis procedure. Protocols may vary from facility to facility.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Observe the amniocentesis site for bleeding, inflammation, or hematoma formation.

Instruct the patient in the care and assessment of the amniocentesis site. Instruct the patient to report any redness, edema, bleeding, or pain at the site. Instruct the patient to keep the site clean and change the dressing as needed.

Instruct the patient to expect mild cramping, leakage of small amount of amniotic fluid, and vaginal spotting for up to 2 days following the procedure. Instruct the patient to immediately report moderate to severe abdominal pain or cramps, change in fetal activity, increased or prolonged leaking of amniotic fluid from abdominal needle site, vaginal bleeding that is heavier than spotting, and either chills or fever to the HCP.

Instruct the patient to rest until all symptoms have disappeared before resuming normal levels of activity.

Administer standard dose of Rh(D) immune globulin RhoGAM IM or Rhophylac IM or IV to maternal Rh-negative patients to prevent maternal Rh sensitization should the fetus be Rh-positive.

Administer mild analgesic and antibiotic therapy as ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.

Recognize anxiety related to test results, and offer support. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Encourage the family to seek counseling if concerned with pregnancy termination or to seek genetic counseling if a chromosomal abnormality is determined. Decisions regarding elective abortion should take place in the presence of both parents. Provide a nonjudgmental, nontimpressing atmosphere for discussing the risks and difficulties of delivering and raising a developmentally challenged infant, as well as exploring other options (termination of pregnancy or adoption). It is also important to discuss feelings the mother and father may experience (e.g., guilt, depression, anger) if fetal abnormalities are detected.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage her to review corresponding literature provided by a pharmacist.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor...
**Leukocyte Alkaline Phosphatase**

**SYNONYM/ACRONYM:** Synonyms/acronym: LAP, LAP score, LAP smear.

**SPECIMEN:** Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

**REFERENCE VALUE:** (Method: Microscopic evaluation of specially stained blood smears) 25 to 130 (score based on 0 to 4+ rating of 100 neutrophils).

**DESCRIPTION:** Alkaline phosphatase is an enzyme important for intracellular metabolic processes. It is present in the cytoplasm of neutrophilic granulocytes from the metamyelocyte to the segmented stage. Leukocyte alkaline phosphatase (LAP) concentrations may be altered by the presence of infection, stress, chronic inflammatory diseases, Hodgkin’s disease, and hematological disorders. Levels are low in leukemic leukocytes and high in normal white blood cells (WBCs), making this test useful as a supportive test in the differential diagnosis of leukemia. It should be noted that test results must be correlated with the patient’s condition because LAP levels increase toward normal in response to therapy.

**INDICATIONS:**
- Differentiate chronic myelocytic leukemia from other disorders that increase the WBC count
- Monitor response of Hodgkin’s disease to therapy

**RESULT:**

*Increased in:*

*Conditions that result in an increase in leukocytes in all stages of maturity will reflect a corresponding increase in LAP.*

- Aplastic leukemia
- Chronic inflammation
- Down’s syndrome
- Hairy cell leukemia
- Hodgkin’s disease
- Leukemia (acute and chronic lymphoblastic)
- Myelofibrosis with myeloid metaplasia
- Multiple myeloma
- Polycythemia vera (*Increase in all blood cell lines, including leukocytes*)
- Pregnancy

Progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHIES:**
- RELATED MONOGRAPHIES:
  - Related tests include amniotic fluid analysis, antibodies anticardiolipin, blood groups and antibodies, chromosome analysis, fetal fibronectin, α-fetoprotein, glucose, ketones, Kleihauer-Betke test, potassium, US obstetric, and UA.

796 Davis’s Comprehensive Laboratory and Diagnostic Handbook—with Nursing Implications

- Stress
- Thrombocytopenia

**Decreased in:**
- Chronic myelogenous leukemia
- Hereditary hypophosphatemia *(Insufficient phosphorus levels)*
- Idiopathic thrombocytopenia purpura
- Nephrotic syndrome *(Excessive loss of phosphorus)*
- Paroxysmal nocturnal hemoglobinuria *(Possibly related to the lack or absence of LAP and other proteins anchored to the red blood cell wall resulting in complement-mediated hemolysis)*
- Sickle cell anemia
- Sideroblastic anemia

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
Drugs that may increase the LAP score include steroids.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**  
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.  
- Inform the patient that the test is used to evaluate disorders of the hematological system.  
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.  
- Obtain a history of the patient’s hematopoietic and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.  
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.  
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.  
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.  
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**  
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.  
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.  
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.  
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.  
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**  
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.  
- Instruct the patient to avoid exposure to infection if WBC count is decreased.  
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
Lipase

SYNONYM/ACRONYM: Triacylglycerol acylhydrolase.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Enzymatic Spectrophotometry)

| Conventional & SI Units | 3–73 units/L |

DESCRIPTION: Lipases are digestive enzymes secreted by the pancreas into the duodenum. Different lipolytic enzymes have specific substrates, but overall activity is collectively described as lipase. Lipase participates in fat digestion by breaking down triglycerides into fatty acids and glycerol. Lipase is released into the bloodstream when damage occurs to the pancreatic acinar cells. Its presence in the blood indicates pancreatic disease because the pancreas is the only organ that secretes this enzyme.

INDICATIONS:
• Assist in the diagnosis of acute and chronic pancreatitis
• Assist in the diagnosis of pancreatic carcinoma

RESULT:
Increased in:
Lipase is contained in pancreatic tissue and is released into the serum when cell damage or necrosis occurs.
• Acute cholecystitis
• Obstruction of the pancreatic duct
• Pancreatic carcinoma (early)
• Pancreatic cyst or pseudocyst
• Pancreatic inflammation
• Pancreatitis (acute and chronic)
• Renal failure (Lipase is excreted by the kidneys; decreased kidney function will reflect an increase in serum lipase.)

Access additional resources at davisplus.fadavis.com
Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may increase lipase levels include asparaginase, azathioprine, cholinergics, codeine, deoxycholate, didanosine, glycocholate, indomethacin, methacholine, methylprednisolone, morphine, narcotics, pancreozymin, pentazocine, and taurocholate.
• Drugs that may decrease lipase levels include protamine and saline (IV infusions).
• Endoscopic retrograde cholangiopancreatography may increase lipase levels.
• Serum lipase levels increase with hemodialysis. Therefore, predialysis specimens should be collected for lipase analysis.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is primarily used to diagnose pancreatitis.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s gastrointestinal (GI) and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Note any recent procedures that can interfere with test results.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
• Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
• If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
• Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
• Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
• Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
• Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
• A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
• Nutritional considerations: Instruct the patient to ingest small, frequent meals if he or she has a GI disorder; advise the patient to consider other dietary alterations as well. After acute symptoms subside and bowel sounds return, patients are usually prescribed a clear liquid diet, progressing to a low-fat, high-carbohydrate diet.
• Administer vitamin B₁₂, as ordered, to the patient with decreased lipase levels, especially if his or her disease prevents adequate absorption of the vitamin.
• Encourage the alcoholic patient to avoid alcohol and to seek appropriate counseling for substance abuse.
Lipoprotein Electrophoresis

SYNONYM/ACRONYM: Lipid fractionation; lipoprotein phenotyping; \(3g_{\alpha}{}_{1}\)-lipoprotein cholesterol, high-density lipoprotein (HDL); \(\beta\)-lipoprotein cholesterol, low-density lipoprotein (LDL); pre-\(\beta\)-lipoprotein cholesterol, very-low-density lipoprotein (VLDL).

SPECIMEN: Serum (3 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Electrophoresis and 4°C test for specimen appearance) There is no quantitative interpretation of this test. The specimen appearance and electrophoretic pattern is visually interpreted.

<table>
<thead>
<tr>
<th>Hyperlipoproteinemia: Fredrickson Type</th>
<th>Specimen Appearance</th>
<th>Electrophoretic Pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type I</td>
<td>Clear with creamy top layer</td>

</tr>
<tr>
<td>Type V</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

RESULT:
Type I: Hyperlipoproteinemia or increased chylomicrons can be primary, resulting from an inherited deficiency of lipoprotein lipase; or secondary, caused by uncontrolled diabetes, systemic lupus erythematosus, and dysgammaglobulinemia. Total cholesterol is normal to moderately elevated and triglycerides (mostly exogenous chylomicrons) are
grossly elevated. If the condition is inherited, symptoms will appear in childhood.

Type IIa: Hyperlipoproteinemia can be primary, resulting from inherited characteristics; or secondary, caused by uncontrolled hypothyroidism, nephrotic syndrome, and dysgammaglobulinemia. Total cholesterol is elevated, triglycerides are normal, and LDL cholesterol (LDLC) is elevated. If the condition is inherited, symptoms will appear in childhood.

Type IIb: Hyperlipoproteinemia can occur for the same reasons as in type IIa. Total cholesterol, triglycerides, and LDLC are all elevated.

Type III: Hyperlipoproteinemia can be primary, resulting from inherited characteristics; or secondary, caused by hypothyroidism, uncontrolled diabetes, alcoholism, and dysgammaglobulinemia. Total cholesterol and triglycerides are elevated, whereas LDLC is normal.

Type IV: Hyperlipoproteinemia can be primary, resulting from inherited characteristics; or secondary, caused by poorly controlled diabetes, alcoholism, nephrotic syndrome, chronic renal failure, and dysgammaglobulinemia. Total cholesterol is normal to moderately elevated, triglycerides are moderately to grossly elevated, and LDLC is normal.

Type V: Hyperlipoproteinemia can be primary, resulting from inherited characteristics; or secondary, caused by uncontrolled diabetes, alcoholism, nephrotic syndrome, and dysgammaglobulinemia. Total cholesterol is normal to moderately elevated, triglycerides are grossly elevated, and LDLC is normal.

CRITICAL VALUES: N/A

Liver and Spleen Scan

SYNONYM/ACRONYM: Liver and spleen scintigraphy, liver-spleen scan, radionuclide liver scan, spleen scan.

AREA OF APPLICATION: Abdomen.

CONTRAST: IV radioactive technetium-99m sulfur colloid.

DESCRIPTION: The liver and spleen scan is performed to help diagnose abnormalities in the function and structure of the liver and spleen. It is often performed in combination with lung scanning to help diagnose masses or inflammation in the diaphragmatic area. This procedure is useful for evaluating right-upper-quadrant pain, metastatic disease, jaundice, cirrhosis, ascites, traumatic infarction, and radiation-induced organ cellular necrosis. Technetium-99m (Tc-99m) sulfur colloid is injected IV and rapidly taken up through phagocytosis by the reticuloendothelial cells, which normally function to remove
particulate matter, including radioactive colloids in the liver and spleen. False-negative results may occur in patients with space-occupying lesions (e.g., tumors, cysts, abscesses) smaller than 2 cm. This scan can detect portal hypertension, demonstrated by a greater uptake of the radionuclide in the spleen than in the liver. Single-photon emission computed tomography (SPECT) has significantly improved the resolution and accuracy of liver scanning. SPECT enables images to be recorded from multiple angles around the body and reconstructed by a computer to produce images or “slices” representing the organ at different levels. For evaluation of a suspected hemangioma, the patient’s red blood cells are combined with Tc-99m and images are recorded over the liver. To confirm the diagnosis, liver and spleen scans are done in conjunction with computed tomography (CT), magnetic resonance imaging (MRI), ultrasonography (US), and SPECT scans and interpreted in light of the results of liver function tests.

**INDICATIONS:**
- Assess the condition of the liver and spleen after abdominal trauma
- Detect a bacterial or amebic abscess
- Detect and differentiate between primary and metastatic tumor focal disease
- Detect benign tumors, such as adenoma and cavernous hemangiom
- Detect cystic focal disease
- Detect diffuse hepatocellular disease, such as hepatitis and cirrhosis
- Detect infiltrative processes that affect the liver, such as sarcoidosis and amyloidosis
- Determine superior vena cava obstruction or Budd-Chiari syndrome
- Differentiate between splenomegaly and hepatomegaly
- Evaluate the effects of lower abdominal trauma, such as internal hemorrhage
- Evaluate jaundice
- Evaluate liver and spleen damage caused by radiation therapy or toxic drug therapy
- Evaluate palpable abdominal masses

**RESULT:**

**Normal findings in:**
- Normal size, contour, position, and function of the liver and spleen

**Abnormal findings in:**
- Abscesses
- Cirrhosis
- Cysts
- Hemangiomas
- Hematomas
- Hepatitis
- Hodgkin’s disease
- Infarction
- Infection
- Infiltrative process (amyloidosis and sarcoidosis)
- Inflammation of the diaphragmatic area
- Metastatic tumors
- Nodular hyperplasia
- Portal hypertension
- Primary benign or malignant tumors
- Traumatic lesions

**CRITICAL VALUES:**
- Visceral injury

Note and immediately report to the health care provider (HCP) positive results and related symptoms.

**INTERFERING FACTORS:**

*This procedure is contraindicated for:*
- Patients who are pregnant or suspected of being pregnant, unless

Access additional resources at davisplus.fadavis.com
the potential benefits of the procedure far outweigh the risks to the fetus and mother.

**Factors that may impair clear imaging:**
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Other nuclear scans done within the preceding 24 to 48 hr

**Other considerations:**
- The scan may fail to detect focal lesions smaller than 2 cm in diameter.
- Improper injection of the radionuclide may allow the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
- Obtain a history of the patient’s gastrointestinal and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in a nuclear medicine department by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- There are no dietary restrictions prior to the procedure.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**Nursing Implications and Procedure**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses liver and spleen function.

**INTRATEST:**
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
Have emergency equipment readily available.
Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
Observe standard precautions, and follow the general guidelines in Appendix A.
Administer sedative to a child or to an uncooperative adult, as ordered.
Place the patient in a supine position on a flat table with foam wedges, which help maintain position and immobilization.
IV radionuclide is administered and the abdomen is scanned immediately to screen for vascular lesions with images taken in various positions.
The patient may be imaged by SPECT techniques to further clarify areas of suspicious radionuclide localization.

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.
No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
Instruct the patient to resume usual medication and activity, as directed by the HCP.
Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
Instruct the patient in the care and assessment of the injection site. Observe for bleeding, hematoma formation, and inflammation.
If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
Instruct the patient to immediately flush the toilet, and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.

**Nutritional considerations:** A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes. High fat consumption increases the amount of bile acids in the colon and should be avoided.
Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include ALT, antibodies antimitochondrial, AST, bilirubin, biopsy liver, CT abdomen, CT biliary tract and liver, GGT, HAV, HBV, HCV, hepatobiliary scan, MRI abdomen, and US liver.
Refer to the Gastrointestinal and Hepatobiliary System tables at the back of the book for related tests by body system.
Lung Perfusion Scan

SYNONYM/ACRONYM: Radioactive perfusion scan, lung scintiscan, lung perfusion scintigraphy, ventilation-perfusion scan, pulmonary scan, radionuclide perfusion lung scan, V/Q scan.

AREA OF APPLICATION: Chest/thorax.

CONTRAST: IV radioactive material, usually macroaggregated albumin (MAA).

DESCRIPTION: The lung perfusion scan is a nuclear medicine study performed to evaluate a patient for pulmonary embolus (PE) or other pulmonary disorders. Technetium (Tc-99m) is injected IV and distributed throughout the pulmonary vasculature because of the gravitational effect on perfusion. The scan, which produces a visual image of pulmonary blood flow, is useful in diagnosing or confirming pulmonary vascular obstruction. The diameter of the IV injected macroaggregated albumin (MAA) is larger than that of the pulmonary capillaries; therefore, the MAA temporarily becomes lodged in the pulmonary vasculature. A gamma camera detects the radiation emitted from the injected radioactive material, and a representative image of the lung is obtained. This procedure is often done in conjunction with the lung ventilation scan to obtain clinical information that assists in differentiating among the many possible pathological conditions revealed by the procedure. The results are correlated with other diagnostic studies, such as pulmonary function, chest x-ray, pulmonary angiography, and arterial blood gases. A recent chest x-ray is essential for accurate interpretation of the lung perfusion scan. An area of non-perfusion seen in the same area as a pulmonary parenchymal abnormality on the chest x-ray indicates that a PE is not present; the defect may represent some other pathological condition, such as pneumonia.

INDICATIONS:
• Aid in the diagnosis of PE in a patient with a normal chest x-ray
• Detect malignant tumor
• Differentiate between PE and other pulmonary diseases, such as pneumonia, pulmonary effusion, atelectasis, asthma, bronchitis, emphysema, and tumors
• Evaluate perfusion changes associated with congestive heart failure and pulmonary hypertension
• Evaluate pulmonary function preoperatively in a patient with pulmonary disease

RESULT:
Normal findings in:
• Diffuse and homogeneous uptake of the radioactive material by the lungs
**Abnormal findings in:**
- Asthma
- Atelectasis
- Bronchitis
- Chronic obstructive pulmonary disease
- Emphysema
- Left atrial or pulmonary hypertension
- Lung displacement by fluid or chest masses
- Pneumonia
- Pneumonitis
- PE
- Tuberculosis

**Critical Values:**
- Pulmonary embolism

Note and immediately report to the health care provider (HCP) positive results and related symptoms.

**Interfering Factors:**

This procedure is contraindicated for:
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
- Patients with atrial and ventricular septal defects, because the MAA particles will not reach the lungs
- Patients with pulmonary hypertension

Factors that may impair clear imaging:
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Other nuclear scans done on the same day

Other considerations:
- Improper injection of the radionuclide may allow the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation.

---

**Nursing Implications and Procedure**

**Pretest:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses blood flow to the lungs.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- Obtain a history of the patient’s respiratory system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that
the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department, by a HCP specializing in this procedure, with support staff, and takes approximately 60 min. Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure. There are no food, fluid or medication restrictions, unless by medical direction.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Record baseline vital signs and assess neurological status. Protocols may vary from facility to facility.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in a supine position on a flat table with foam wedges, which help maintain position and immobilization.
- IV radionuclide is administered and the abdomen is scanned immediately to screen for vascular lesions with images taken in various positions.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- Remove the needle or catheter and apply a pressure dressing over the puncture site.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- Monitor vital signs and neurological status every 15 min for one hr, then every 2 hr for 4 hr, and then as ordered by HCP. Compare with baseline values. Protocols may vary from facility to facility.
- Instruct the patient to resume usual medication and activity, as directed by the HCP.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the injection site. Observe for bleeding, hematoma formation, and inflammation.
- If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- Instruct the patient to immediately flush the toilet, and to meticulously wash hands with soap and water after
Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**Related Monographs:**
- Related tests include α-1 AT, eosinophil count, ACE, alveolar/arterial gradient, angiography pulmonary, biopsy lung, blood gases, blood pool imaging, bronchoscopy, carbon dioxide, chest x-ray, complete blood count, complete blood count, CT thoracic, complete blood count, WBC count and differential, culture and smear mycobacteria, culture blood, culture throat, culture sputum, culture viral, cytology sputum, ESR, IgE, gallium scan, lung ventilation scan, MRI chest, mediastinoscopy, plethysmography, pleural fluid analysis, PET heart, PFT, pulse oximetry, and TB skin tests.
- Refer to the Respiratory System table at the back of the book for related tests by body system.

**Nutritional Considerations:** A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.

Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

**Synonym/Acronym:** Radioactive ventilation scan, VQ lung scan, aerosol lung scan, ventilation scan, xenon lung scan.

**Area of Application:** Chest/thorax.

**Contrast:** Done with inhaled radioactive material (xenon gas or technetium-DTPA).

**Description:** The lung ventilation scan is a nuclear medicine study performed to evaluate a patient for pulmonary embolus (PE) or other pulmonary disorders. It can evaluate respiratory function (i.e., demonstrating areas of the lung that are patent and capable of ventilation) and dysfunction (e.g., parenchymal abnormalities affecting ventilation, such as pneumonia). The procedure is performed after the patient inhales air mixed with a radioactive gas through a face mask and mouthpiece. The radioactive gas delineates areas of the lung during...
ventilation. The distribution of the gas throughout the lung is measured in three phases:

- **Wash-in phase:** Phase during buildup of the radioactive gas
- **Equilibrium phase:** Phase after the patient rebreathes from a closed delivery system
- **Wash-out phase:** Phase after the radioactive gas has been removed

This procedure is usually performed along with a lung perfusion scan. When PE is present, ventilation scans display a normal wash-in and wash-out of radioactivity from the lung areas. Parenchymal disease responsible for perfusion abnormalities will produce abnormal wash-in and wash-out phases. This test can be used to quantify regional ventilation in patients with pulmonary disease.

**INDICATIONS:**
- Aid in the diagnosis of PE
- Differentiate between PE and other pulmonary diseases, such as pneumonia, pulmonary effusion, atelectasis, asthma, bronchitis, emphysema, and tumors
- Evaluate regional respiratory function
- Identify areas of the lung that are capable of ventilation
- Locate hypoventilation (regional), which can result from chronic obstructive pulmonary disease (COPD) or excessive smoking

**RESULT:**

- **Normal findings in:**
  - Equal distribution of radioactive gas throughout both lungs and a normal wash-out phase

- **Abnormal findings in:**
  - Atelectasis
  - Bronchitis

- Bronchogenic carcinoma
- COPD
- Emphysema
- PE
- Pneumonia
- Regional hypoventilation
- Sarcoidosis
- Tuberculosis
- Tumor

**CRITICAL VALUES:**
- Pulmonary embolism

Note and immediately report to the health care provider (HCP) positive results and related symptoms.

**INTERFERING FACTORS:**

- **This procedure is contraindicated for:**
  - Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

- **Factors that may impair clear imaging:**
  - Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
  - Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
  - Other nuclear scans done within the preceding 24 to 48 hr

- **Other considerations:**
  - The presence of conditions that affect perfusion or ventilation (e.g., tumors that obstruct the pulmonary artery, vasculitis, pulmonary edema, sickle cell disease, parasitic disease, emphysema, effusion, infection) can simulate a perfusion defect similar to PE
  - Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses airflow to the lungs.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- Obtain a history of the patient’s respiratory system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department, usually by a HCP who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Record baseline vital signs and assess neurological status. Protocols may vary from facility to facility.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in a supine position on a flat table with foam wedges, which help maintain position and immobilization.
- The radionuclide is administered through a mask, which is placed over the patient’s nose and mouth. The patient is asked to hold his or her breathe for a short period of time while the scan is taken.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
POST-TEST:

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- Evaluate the patient’s vital signs. Monitor vital signs and neurological status every 15 min for one hr, then every 2 hr for 4 hr, and then as ordered by HCP. Compare with baseline values. Protocols may vary from facility to facility.
- Instruct the patient to resume medication, or activity, as directed by the HCP.
- Advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- Instruct the patient to immediately flush the toilet, and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.

Nutritional considerations: A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.

- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include α-1 antitrypsin, alveolar/arterial ratio, ACE, angiography pulmonary, biopsy lung, blood gases, blood pool imaging, bronchoscopy, carbon dioxide, chest x-ray, complete blood count, complete blood count, CT thorax, complete blood count, WBC count and differential, culture and smear mycobacteria, culture blood, culture sputum, culture throat, culture viral, cytology sputum, ß-dimer, gallium scan, lung perfusion scan, MRI chest, mediastinoscopy, plethysmography, pleural fluid analysis, PET heart, PFT, TB skin tests, US venous doppler extremity studies, and venography.

- Refer to the Respiratory System table at the back of the book for related tests by body system.
**Lupus Anticoagulant Antibodies**

**SYNONYM/ACRONYM:** Lupus inhibitor phospholipid type, lupus antiphospholipid antibodies, LA.

**SPECIMEN:** Plasma (1 mL) collected in blue-top (sodium citrate) tube.

**REFERENCE VALUE:** (Method: Dilute Russell viper venom test time) Negative.

**DESCRIPTION:** Lupus anticoagulant antibodies (LA) are immunoglobulins, usually of the immunoglobulin G class. They are also referred to as lupus antiphospholipid antibodies because they interfere with phospholipid-dependent coagulation tests such as activated partial thromboplastin time (aPTT) by reacting with the phospholipids in the test system. They are not associated with a bleeding disorder unless thrombocytopenia or antiprothrombin antibodies are already present. They are associated with an increased risk of thrombosis.

- Rheumatoid arthritis (*LA can be detected with this condition and can cause vascular inflammation.*)
- Systemic lupus erythematosus (*Related to formation of thrombi as a result of LA binding to phospholipids on cell walls.*)
- Thromboembolism (*Related to formation of thrombi as a result of LA binding to phospholipids on cell walls.*)

**Negative findings in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may cause a positive LA test result include calcium channel blockers, chlorpromazine, heparin, hydralazine, hydantoin, isoniazid, methyldopa, phenytoin, phenothiazine, procainamide, quinine, quinidine, and thorazine.
- Placement of a tourniquet for longer than 1 min can result in venous stasis and changes in the concentration of plasma proteins to be measured. Platelet activation may also occur under these conditions, causing erroneous results.
- Vascular injury during phlebotomy can activate platelets and coagulation factors, causing erroneous results.

**INDICATIONS:**
- Evaluate prolonged aPTT
- Investigate reasons for fetal death

**RESULT:**

**Positive findings in:**
- Fetal loss (*Thrombosis associated with LA can form clots that lodge in the placenta and disrupt nutrition to the fetus.*)
- Raynaud’s disease (*LA can be detected with this condition and can cause vascular inflammation.*)

Access additional resources at davisplus.fadavis.com
Hemolyzed specimens must be rejected because hemolysis is an indication of platelet and coagulation factor activation.

- Incompletely filled tubes contaminated with heparin or clotted specimens must be rejected.
- Icteric or lipemic specimens interfere with optical testing methods, producing erroneous results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate coagulation disorders.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic, immune, musculoskeletal, and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Heparin therapy should be discontinued 2 days before specimen collection, with medical direction. Coumarin therapy should be discontinued 2 wk before specimen collection, with medical direction.

There are no food or fluid restrictions, unless by medical direction.

INTRATEST:

- Ensure that the patient has complied with pretesting preparations; assure that anticoagulant therapy has been restricted as required prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. Important note: Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It is important to ask the laboratory which concentration it recommends, because each concentration will have its own specific reference range.
- When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and red-top tubes. When coagulation testing is the only test to be done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with tissue thromboplastin, which can falsely decrease values.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture.
Luteinizing Hormone

SYNONYM/ACRONYM: LH, luteotropin, interstitial cell–stimulating hormone (ICSH).

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Immunoassay)

### DESCRIPTION:
Luteinizing hormone (LH) is secreted by the anterior pituitary gland in response to stimulation by gonadotropin-releasing hormone, the same hypothalamic releasing factor that stimulates follicle-stimulating hormone release. LH affects gonadal function in both men and women. In women, a surge of LH normally occurs at the midpoint of the menstrual cycle (ovulatory phase); this surge is believed to be induced by high estrogen levels. LH causes the ovum to be expelled from the ovary and stimulates development of the corpus luteum and progesterone production. As progesterone levels rise, LH production decreases. In males, LH stimulates the interstitial cells of Leydig, located in the testes, to produce testosterone. For this reason, in reference to males, LH is sometimes called interstitial cell-stimulating hormone. Secretion of LH is pulsatile and follows a circadian rhythm in response to the normal intermittent secretion of gonadotropin-releasing hormone.

### INDICATIONS:
- Distinguish between primary and secondary causes of gonadal failure
- Evaluate children with precocious puberty
- Evaluate male and female infertility, as indicated by decreased LH levels
- Evaluate response to therapy to induce ovulation
- Support diagnosis of infertility caused by anovulation, as evidenced by lack of LH surge at the midpoint of the menstrual cycle

### RESULT:
**Increased in:**
Conditions of decreased gonadal function cause a feedback response that stimulates LH secretion.
- Anorchia
- Gonadal failure
- Menopause
- Primary gonadal dysfunction
Decreased in:
- Anorexia nervosa *(Pathophysiology is not clear)*
- Kallmann’s syndrome *(Pathophysiology is not clear)*
- Malnutrition *(Pathophysiology is not clear)*
- Pituitary or hypothalamic dysfunction *(These organs control production of LH; failure of the pituitary to produce LH or of the hypothalamus to produce gonadotropin-releasing hormone results in decreased LH levels)*
- Severe stress *(Pathophysiology is not clear)*

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs and hormones that may increase LH levels include clomiphene, gonadotropin-releasing hormone, goserelin, ketoconazole, mestranol, nafarelin, naloxone, nilutamide, spironolactone, and tamoxifen.
- Drugs and hormones that may decrease LH levels include anabolic steroids, anticonvulsants, conjugated estrogens, danazol, digoxin, D-Trp-6-LHRH, estrogen/progestin therapy, goserelin, megestrol, norethindrone, octreotide, oral contraceptives, phenothiazine, pimozide, pravastatin, progesterone, stanozolol, and tamoxifen.
- In menstruating women, values vary in relation to the phase of the menstrual cycle.
- LH secretion follows a circadian rhythm, with higher levels occurring during sleep.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include ACTH, antisperm antibody, estradiol, FSH, progesterone, prolactin, and testosterone.

Refer to the Endocrine and Reproductive System tables at the end of the book for related tests by body system.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include ACTH, antisperm antibody, estradiol, FSH, progesterone, prolactin, and testosterone.

Refer to the Endocrine and Reproductive System tables at the end of the book for related tests by body system.

Lyme Antibody

SYNONYM/ACRONYM: N/A.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Indirect immunofluorescence) Negative.

DESCRIPTION: *Borrelia burgdorferi*, a deer tick–borne spirochete, is the organism that causes Lyme disease. Lyme disease affects multiple systems and is characterized by fever, arthralgia, and arthritis. The circular, red rash characterizing erythema migrans can appear 3 to 30 days after the tick bite. About one-half of patients in the early stage of Lyme disease (stage 1) and generally all of those in the advanced stage (stage 2)—with cardiac, neurologic, and rheumatoid manifestations—will have a positive test result.

Patients in remission will also have a positive test response. The presence of immunoglobulin M (IgM) antibodies indicates acute infection. The presence of IgG antibodies indicates current or past infection.

INDICATIONS:

Assist in establishing a diagnosis of Lyme disease

RESULT:

Positive findings in: Lyme disease
Negative findings in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• High rheumatoid-factor titers as well as cross-reactivity with Epstein-Barr virus and other spirochetes (e.g., *Rickettsia, Treponema*) may cause false-positive results.
• Positive test results should be confirmed by the Western blot method.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to detect antibodies to the organism that causes Lyme disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune and musculoskeletal systems, symptoms, a history of exposure, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm diagnosis. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Advise the patient to wear light-colored clothing that covers extremities when in areas infested by deer ticks, and to check body for ticks after returning from infested area.
- Recognize anxiety related to test results, and be supportive of impaired activity related to perceived loss of independence, and fear of shortened life expectancy. Lyme disease can be debilitating and can result in significant changes in lifestyle. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Warn the patient that false-positive test results can occur and that false-negative test results frequently occur. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- A related test is synovial fluid analysis.
- Refer to the Immune and Musculoskeletal System tables at the back of the book for related tests by body system.

---

**Lymphangiography**

**SYNONYM/ACRONYM:** Lymphangiogram.

**AREA OF APPLICATION:** Lymphatic system.

**CONTRAST:** IV iodine based contrast medium.

**DESCRIPTION:** Lymphangiography involves visualization of the lymphatic system after the injection of an iodinated oil-based contrast medium into a lymphatic vessel in the hand or foot. The lymphatic system consists of lymph vessels and nodes. Assessment of this system is important because cancer (lymphomas and Hodgkin’s disease) often spreads via the lymphatic system. When the lymphatic system becomes obstructed, painful edema of the extremities usually results. The procedure is usually performed for cancer staging in patients with an established diagnosis of lymphoma or metastatic tumor. Injection into the hand allows visualization of the axillary and supraclavicular nodes. Injection into the foot allows visualization of the lymphatics of the leg, inguinal and iliac regions, and retroperitoneum up to the thoracic duct. Less commonly, injection into the foot can be used to visualize the cervical region (retroauricular area). This procedure can assess progression of the disease, assist in planning surgery, and monitor the effectiveness of chemotherapy or radiation treatment.

**INDICATIONS:**
- Determine the extent of adenopathy
• Determine lymphatic cancer staging
• Distinguish primary from secondary lymphedema
• Evaluate edema of an extremity without known cause
• Evaluate effects of chemotherapy or radiation therapy
• Plan surgical treatment or evaluate effectiveness of chemotherapy or radiation therapy in controlling malignant tumors

RESULT:

Normal findings in:
• Normal lymphatic vessels and nodes that fill completely with contrast medium on the initial films. On 24-hr images, the lymph nodes are fully opacified and well circumscribed. The lymphatic channels are emptied a few hr after injection of the contrast medium.

Abnormal findings in:
• Abnormal lymphatic vessels
• Hodgkin’s disease
• Metastatic tumor involving the lymph glands
• Nodal lymphoma
• Retroperitoneal lymphomas associated with Hodgkin’s disease

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with pulmonary insufficiencies, cardiac diseases, or severe renal or hepatic disease.
• Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
• Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
• Patients who are in renal failure.
• Young patients (17 y.o. and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.

Factors that may impair clear imaging:
• Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
• Retained barium from a previous radiological procedure
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Inability to cannulate the lymphatic vessels

Other considerations:
• Be aware of risks associated with the contrast medium. The oil-based contrast medium may embolize into the lungs and will temporarily diminish pulmonary function. This can produce lipid pneumonia, which is a life-threatening complication.
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead
apron or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the lymphatic system.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to iodine, latex, seafood, anesthetics, or contrast mediums.
- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before lymphangiography.
- Obtain a history of the patient’s endocrine and immunological systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain and explain there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is performed by a HCP, with support staff, and takes approximately 1 to 2 hr. Inform the patient that he or she will have to return the next day, and the set of images taken upon return will take only 30 min.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- Instruct patient to withhold anticoagulant medication or to reduce dosage before the procedure, as ordered by the HCP.
- There are no food or fluid restrictions, unless by medical direction.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**
- Ensure the patient has complied with medication restrictions and pretesting preparations.
- Ensure the patient has removed all external metallic objects from the area to be examined.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Have emergency equipment readily accessible.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to remain still throughout the procedure because movement produces unreliable results.
- Obtain and record baseline vital signs, and assess neurological status.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer a mild sedative, as ordered.
- Place the patient in a supine position on an x-ray table. Cleanse the selected area and cover with a sterile drape.
LYMPHANGIOGRAPHY

A local anesthetic is injected at the site, and a small incision is made or a needle inserted. A blue dye is injected intradermally into the area between the toes or fingers. The lymphatic vessels are identified as the dye moves. A local anesthetic is then injected into the dorsum of each foot or hand, and a small incision is made and cannulated for injection of the contrast medium.

The contrast medium is then injected, and the flow of the contrast medium is followed by fluoroscopy or images. When the contrast medium reaches the upper lumbar level, the infusion of contrast medium is discontinued. X-ray images are taken of the chest, abdomen, and pelvis to determine the extent of filling of the lymphatic vessels. Twenty-four–hr delayed images are taken to examine the lymphatic nodes and to monitor the progress of delayed flow.

Monitor the patient for complications related to the contrast medium (e.g., allergic reaction, anaphylaxis, bronchospasm).

When the procedure is complete, the cannula is removed and the incision sutured and bandaged.

POST-TEST:

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Monitor vital signs and neurological status every 15 min for 30 min. Compare with baseline values. Protocols may vary from facility to facility.

Observe the cannula insertion site for bleeding, inflammation, or hematoma formation.

Observe for a delayed allergic reaction to contrast medium or pulmonary embolus, which may include shortness of breathe, increased heart rate, pleuritic pain, hypotension, low-grade fever, and cyanosis.

Advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

Instruct the patient to resume usual medications, as directed by the HCP.

Instruct the patient to maintain bed rest up to 24 hr to reduce extremity swelling after the procedure, or as ordered.

Instruct the patient to apply cold compresses to the cannulated site as needed, to reduce discomfort or edema.

Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include biopsy bone marrow, biopsy lymph nodes, complete blood count, complete blood count, WBC count and differential, CT abdomen, CT pelvis, CT thoracic, gallium scan, laparoscopy abdominal, liver and spleen scan, MRI abdomen, mediastinoscopy, and US lymph nodes.

Refer to the Endocrine and Immune System tables in the back of the book for tests by related body system.
Magnesium, Blood

SYNONYM/ACRONYM: Mg$^{2+}$.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

DESCRIPTION: Magnesium is required as a cofactor in numerous crucial enzymatic processes, such as protein synthesis, nucleic acid synthesis, and muscle contraction. Magnesium is also required for the use of adenosine diphosphate as a source of energy. It is the fourth most abundant cation and the second most abundant intracellular ion. Magnesium is needed for the transmission of nerve impulses and muscle relaxation. It controls absorption of sodium, potassium, calcium, and phosphorus; utilization of carbohydrate, lipid, and protein; and activation of enzyme systems that enable the B vitamins to function. Magnesium is also essential for oxidative phosphorylation, nucleic acid synthesis, and blood clotting. Urine magnesium levels reflect magnesium deficiency before serum levels. Magnesium deficiency severe enough to cause hypocalcemia and cardiac arrhythmias can exist despite normal serum magnesium levels. It can lead to excessive ventricular irritability.

- Evaluate known or suspected disorders associated with altered magnesium levels
- Monitor the effects of various drugs on magnesium levels

RESULT:

Increased in:
- Addison’s disease *(Related to insufficient production of aldosterone; decreased renal excretion)*
- Adrenocortical insufficiency *(Decreased renal excretion)*
- Dehydration *(Decreased volume reflects hemoconcentration)*
- Diabetic acidosis (severe) *(Disturbance is a function of acid-base imbalance)*
- Hypothyroidism *(Pathophysiology is unclear)*
- Massive hemolysis *(Intracellular concentration is three times higher than normal plasma levels)*
- Overuse of antacids *(Excessive intake of magnesium-containing antacids)*
- Renal insufficiency *(Related to decreased urinary excretion)*
- Tissue trauma

Decreased in:
- Alcoholism *(Related to increased renal excretion and possible insufficient dietary intake)*

INDICATIONS:
- Determine electrolyte balance in renal failure and chronic alcoholism
- Evaluate cardiac arrhythmias (decreased magnesium levels can
MAGNESIUM, BLOOD

• Diabetic acidosis (*Insulin treatment lowers blood glucose and appears to increase intracellular transport of magnesium*)
• Glomerulonephritis (chronic) (Related to diminished renal function; magnesium is reabsorbed in the renal tubules)
• Hemodialysis (*Loss of magnesium due to dialysis treatment*)
• Hyperaldosteronism (Related to increased excretion)
• Hypocalcemia (Decreased magnesium is associated with decreased calcium and vitamin D levels)
• Hypoparathyroidism (Related to decreased calcium)
• Inadequate intake
• Inappropriate secretion of antidiuretic hormone (Related to fluid overload)
• Long-term hyperalimentation
• Malabsorption (Related to impaired absorption of calcium and vitamin D)
• Pancreatitis (Secondary to alcoholism)
• Pregnancy
• Severe loss of body fluids (Diarrhea, lactation, sweating, laxative abuse)

CRITICAL VALUES:

Less than 1.2 mg/dL
Greater than 4.9 mg/dL

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms.

Symptoms such as tetany, weakness, dizziness, tremors, hyperactivity, nausea, vomiting, and convulsions occur at decreased (less than 1.2 mg/dL) concentrations. Electrocardiographic (ECG) changes (prolonged P-R and Q-T intervals, broad flat T waves, and ventricular tachycardia) may also occur. Treatment may include IV or oral administration of magnesium salts, monitoring for respiratory depression and areflexia (IV administration of magnesium salts), and monitoring for diarrhea and metabolic alkalosis (oral administration to replace magnesium).

Respiratory paralysis, decreased reflexes, and cardiac arrest occur at grossly elevated (greater than 15 mg/dL) levels. ECG changes, such as prolonged P-R and Q-T intervals, and bradycardia may be seen. Toxic levels of magnesium may be reversed with the administration of calcium, dialysis treatments, and removal of the source of excessive intake.

INTERFERING FACTORS:

• Drugs that may increase magnesium levels include acetylsalicylic acid and progesterone.
• Drugs that may decrease magnesium levels include albuterol, aminoglycosides, amphotericin B, bendroflumethiazide, chlorthalidone, cisplatin, citrates, cyclosporines, digoxin, gentamicin, glucagon, and oral contraceptives.
• Hemolysis results in a false elevation in values; such specimens should be rejected for analysis.
• Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is present in the IV solution, falsely increasing the result.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
Inform the patient that the test is used to assist in the evaluation of electrolyte balance.

Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of the patient’s cardiovascular, endocrine, gastrointestinal, genitourinary, and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

INRTEST:

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Nutritional considerations: Educate the magnesium-deficient patient regarding good dietary sources of magnesium, such as green vegetables, seeds, legumes, shrimp, and some bran cereals. Advise the patient that high intake of substances such as phosphorus, calcium, fat, and protein interferes with the absorption of magnesium.

Instruct the patient to report any signs or symptoms of electrolyte imbalance, such as dehydration, diarrhea, vomiting, or prolonged anorexia.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.

Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPH:

Related tests include ACTH, aldosterone, anion gap, antiarrhythmic drugs, AST, BUN, calcium, calculus kidney stone panel, complete blood count, WBC count and differential, cortisol, CRP, CK and isoenzymes, creatinine, glucose, homocysteine, LDH and isoenzymes, magnesium urine, myoglobin, osmolality, PTH, phosphorus, potassium, renin, sodium, troponin, and vitamin D.

Refer to the Cardiovascular, Endocrine, Gastrointestinal, Genitourinary, and Reproductive System tables at the back of the book for related tests by body system.
Magnesium, Urine

SYNONYM/ACRONYM: Urine Mg²⁺.

SPECIMEN: Urine (5 mL) from a random or timed specimen collected in a clean plastic collection container with 6N hydrochloride as a preservative.

REFERENCE VALUE: (Method: Spectrophotometry)

<table>
<thead>
<tr>
<th>Conventional</th>
<th>Alternative Units (Conventional Units × 0.8229)</th>
<th>SI Units (Conventional Units × 0.4114)</th>
</tr>
</thead>
<tbody>
<tr>
<td>7.3–12.2 mg/24 hr</td>
<td>6.0–10.0 mEq/24 hr</td>
<td>3.0–5.0 mmol/24 hr</td>
</tr>
</tbody>
</table>

DESCRIPTION: Magnesium is required as a cofactor in numerous crucial enzymatic processes, such as protein synthesis, nucleic acid synthesis, and muscle contraction. Magnesium is also required for the use of adenosine diphosphate as a source of energy. It is the fourth most abundant cation and the second most abundant intracellular ion. Magnesium is needed for the transmission of nerve impulses and muscle relaxation. It controls absorption of sodium, potassium, calcium, and phosphorus; utilization of carbohydrate, lipid, and protein; and activation of enzyme systems that enable the B vitamins to function. Magnesium is also essential for oxidative phosphorylation, nucleic acid synthesis, and blood clotting. Urine magnesium levels reflect magnesium deficiency before serum levels. Magnesium deficiency severe enough to cause hypocalcemia and cardiac arrhythmias can exist despite normal serum magnesium levels.

Regulating electrolyte balance is one of the major functions of the kidneys. In normally functioning kidneys, urine levels increase when serum levels are high and decrease when serum levels are low to maintain homeostasis. Analyzing these urinary levels can provide important clues as to the functioning of the kidneys and other major organs. Tests for electrolytes, such as magnesium, in urine usually involve timed urine collections over a 12- or 24-hr period. Measurement of random specimens may also be requested.

INDICATIONS:
- Determine the potential cause of renal calculi
- Evaluate known or suspected endocrine disorder
- Evaluate known or suspected renal disease
- Evaluate magnesium imbalance
- Evaluate a malabsorption problem

RESULT:

Increased in:
- Alcoholism (Related to impaired absorption and increased urinary excretion)
Bartter’s syndrome (Inherited defect in renal tubules that results in urinary wasting of potassium and magnesium)

• Transplant recipients on cyclosporine and prednisone (These medications cause the kidney to increase excretion)
• Use of corticosteroids (These medications cause the kidney to increase excretion)
• Use of diuretics (Increased urinary excretion)

Decreased in:

• Abnormal renal function (Related to diminished ability of renal tubules to reabsorb magnesium)
• Crohn’s disease (Related to inadequate intestinal absorption)
• Inappropriate secretion of antidiuretic hormone (Related to diminished renal absorption)
• Salt-losing conditions (Related to diminished renal absorption)

CRITICAL VALUES: N/A

INTERFERING FACTORS:

• Drugs that may increase urine magnesium levels include cisplatin, cyclosporine, ethacrynic acid, furosemide, mercaptomerin, mercurial diuretics, and thiazides.
• Drugs that may decrease urine magnesium levels include amiloride, angiotensin, oral contraceptives, parathyroid extract, and phosphates.
• Magnesium levels follow a circadian rhythm, and for this reason 24-hr collections are recommended.
• All urine voided for the timed collection period must be included in the collection, or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

PRETEST:

• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to evaluate magnesium balance.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s endocrine, gastrointestinal, and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure.
• Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
• Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container. Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• Instruct the patient to avoid excessive exercise and stress during the 24-hr collection of urine.
There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- Ensure that the patient has complied with activity restrictions during the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection.

**Random Specimen (Collect in Early Morning):**

**Clean-Catch Specimen:**
- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

**Indwelling Catheter:**
- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

**Timed Specimen:**
- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container’s label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

**Nutritional considerations:** Educate the magnesium-deficient patient regarding good dietary sources of magnesium, such as green vegetables, seeds, legumes, shrimp, and some bran cereals. Advise the patient that high intake of substances such as phosphorus, calcium, fat, and protein interferes with the absorption of magnesium.
- Instruct the patient to report any signs or symptoms of electrolyte imbalance, such as dehydration, diarrhea, vomiting, or prolonged anorexia.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**Related Monographs:**

- Related tests include ACTH, aldosterone, angiography renal, anion gap, BUN, calcium, calculus kidney stone panel, CT renal, cortisol, creatinine, glucose, IVP, magnesium, osmolality, PTH, phosphorus, potassium, renin, renogram, sodium, troponin, UA, US kidney, and vitamin D.

Refer to the Endocrine, Gastrointestinal, and Genitourinary System tables at the back of the book for related tests by body system.

---

**Magnetic Resonance Angiography**

**SYNONYM/ACRONYM:** MRA.

**Area of Application:** Vascular.

**Contrast:** Can be done with or without IV contrast (gadolinium).

**Description:** Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position; this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of the vessels in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography. MRA is particularly useful for visualizing vascular abnormalities, dissections, and other pathology. Special imaging sequences allow the visualization of moving blood within the vascular system. Two common techniques to obtain images of flowing blood are time-of-flight and phase-contrast MRA. In time-of-flight imaging, incoming blood makes the vessels appear bright and surrounding tissue is suppressed. Phase-contrast images are produced by subtracting the stationary tissue surrounding the vessels where the blood is moving through vessels during the imaging, producing high-contrast images. MRA is the most accurate...
MAGNETIC RESONANCE ANGIOGRAPHY

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients with certain ferrous metal prosthetics, valves, aneurysm clips, inner ear prostheses, or other metallic objects
- Patients with metal in their body, such as shrapnel or ferrous metal in the eye
- Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
- Use of gadolinium-based contrast agents (GBCA) is contraindicated in patients with acute or chronic severe renal insufficiency (glomerular filtration rate less than 30 mL/min/1.73m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non–contrast-enhanced diagnostic studies.
- Patients who are claustrophobic
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
- Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients with extreme cases of claustrophobia, unless sedation is given before the study

Access additional resources at davisplus.fadavis.com
Other considerations:

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the vascular system.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- Obtain a history of results of the patient’s cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.
- Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- Note any recent procedures that can interfere with test results.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix F).
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in an MRI department by a health care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.
- Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove external metallic objects from the area to be examined prior to the procedure. There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

- Ensure that the patient has removed external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout
the procedure because movement produces unreliable results.

- Observe standard precautions, and follow the general guidelines in Appendix A.
- Supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.
- If an electrocardiogram or respiratory gating is to be performed in conjunction with the scan, apply MRI-safe electrodes to the appropriate sites.
- Establish IV fluid line for the injection of emergency drugs and sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in the supine position on an exam table.
- If contrast is used, imaging can begin shortly after the injection.
- Ask the patient to inhale deeply and hold his or her breathe while the images are taken, and then to exhale after the images are taken.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- Remove the needle or catheter and apply a pressure dressing over the puncture site.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the injection site.
- Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.

**RELATED MONOGRAPHS:**

- Related tests include angiography of the body area of interest, BUN, CT angiography, creatinine, US arterial Doppler carotid, and US venous Doppler.
- Refer to the Cardiovascular System table at the back of the book for related tests by body system.
Magnetic Resonance Imaging, Abdomen

SYNONYM/ACRONYM: Abdominal MRI.

AREA OF APPLICATION: Liver/abdominal area.

CONTRAST: Can be done with or without IV contrast medium (gadolinium).

DESCRIPTION: Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radio frequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position; this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of the abdomen in multiple planes without the use of ionizing radiation or the interference of bone.

Abdominal MRI is performed to assist in diagnosing abnormalities of abdominal and hepatic structures. Contrast-enhanced imaging is effective for distinguishing peritoneal metastases from primary tumors of the gastrointestinal tract. Primary tumors of the stomach, pancreas, colon, and appendix often spread by intraperitoneal tumor shedding and subsequent peritoneal carcinomatosis. MRI uses the noniodinated contrast medium gadopentetate dimeglumine (Magnevist), which is administered IV to enhance contrast differences between normal and abnormal tissues.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography (see monograph titled “Magnetic Resonance Angiography”).

INDICATIONS:
- Detect abdominal aortic diseases
- Detect and stage cancer (primary or metastatic tumors of liver, pancreas, prostate, uterus, and bladder)
- Detect chronic pancreatitis
- Detect renal vein thrombosis
- Detect soft tissue abnormalities
- Determine and monitor tissue damage in renal transplant patients
- Determine the presence of blood clots, cysts, fluid or fat accumulation in tissues, hemorrhage, and infarctions
- Determine vascular complications of pancreatitis, venous thrombosis, or pseudoaneurysm
• Differentiate aortic aneurysms from tumors near the aorta
• Differentiate liver tumors from liver abnormalities, such as cysts, cavernous hemangiomas, and hepatic amebic abscesses
• Evaluate postoperative angioplasty sites and bypass grafts
• Monitor and evaluate the effectiveness of medical or surgical interventions and the course of the disease

RESULT:

Normal findings in:
• Normal anatomic structures, soft tissue density, and biochemical constituents of body tissues, including blood flow

Abnormal findings in:
• Acute tubular necrosis
• Aneurysm
• Cholangitis
• Glomerulonephritis
• Hydronephrosis
• Internal bleeding
• Masses, lesions, infections, or inflammations
• Renal vein thrombosis
• Vena cava obstruction

CRITICAL VALUES:
• Acute GI bleed
• Aortic aneurysm
• Infection
• Tumor with significant mass effect

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
• Patients with metal in their body, such as shrapnel or ferrous metal in the eye
• Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
• Use of gadolinium-based contrast agents (GBCA) is contraindicated in patients with acute or chronic severe renal insufficiency (glomerular filtration rate less than 30 mL/min/1.73m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non–contrast-enhanced diagnostic studies.
• Patients with intrauterine devices
• Patients with iron pigments in tattoos
• Patients who are claustrophobic
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
• Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized

Other considerations:
• If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.
Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
Inform the patient that the procedure assesses the organs and structures inside the abdomen.
Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
Obtain a history of the patient’s gastrointestinal, genitourinary, and hepatobiliary systems, symptoms, and results of previously performed laboratory tests, diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.
Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
Obtain a list of the patient’s current medications including herbs, nutritional supplements, and nutraceuticals.
Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in an MRI department by a health care provider (HCP) specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives.
Instruct the patient to remove jewelry and all other metallic objects from the area to be examined prior to the procedure.
Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
Observe standard precautions, and follow the general guidelines in Appendix A.
Supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.
Establish an IV fluid line for the injection of emergency drugs and of sedatives.
Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
Place the patient in the supine position on an exam table.
If contrast is used, imaging can begin shortly after the injection.
Ask the patient to inhale deeply and hold his or her breathe while the images are taken and then to exhale after the images are taken.
Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
Remove the needle or catheter and apply a pressure dressing over the puncture site.

**POST-TEST:**
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting

Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output
Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
Instruct the patient in the care and assessment of the injection site.
Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
Related tests include ACTH and challenge tests, angiography abdomen, BUN, cortisol and challenge tests, CT abdomen; creatinine, KUB study, and US liver and biliary system.
Refer to the Gastrointestinal, Genitourinary, and Hepatobiliary System tables at the back of the book for related tests by body system.
Magnetic Resonance Imaging, Brain

**SYNONYM/ACRONYM:** Brain MRI.

**AREA OF APPLICATION:** Brain area.

**CONTRAST:** Can be done with or without IV contrast medium (gadolinium).

**DESCRIPTION:** Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radiofrequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position; this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of pathological lesions of the brain in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue.

Brain MRI can distinguish solid, cystic, and hemorrhagic components of lesions. This procedure is done to aid in the diagnosis of intracranial abnormalities, including tumors, ischemia, infection, and multiple sclerosis, and in assessment of brain maturation in pediatric patients. Rapidly flowing blood on spin-echo MRI appears as an absence of signal or a void in the vessel’s lumen.

Blood flow can be evaluated in the cavernous and carotid arteries. Aneurysms may be diagnosed without traditional iodine-based contrast angiography, and old clotted blood in the walls of the aneurysms appears white. MRI uses the noniodinated contrast medium gadopentetate dimeglumine (Magnevist), which is administered IV to enhance contrast differences between normal and abnormal tissues.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography (see monograph titled “Magnetic Resonance Angiography”).

**INDICATIONS:**
- Detect and locate brain tumors
- Detect cause of cerebrovascular accident, cerebral infarct, or hemorrhage
- Detect cranial bone, face, throat, and neck soft tissue lesions
- Evaluate the cause of seizures, such as intracranial infection, edema, or increased intracranial pressure
- Evaluate cerebral changes associated with dementia
- Evaluate demyelinating disorders
- Evaluate intracranial infections
- Evaluate optic and auditory nerves
• Evaluate the potential causes of headache, visual loss, and vomiting
• Evaluate shunt placement and function in patients with hydrocephalus
• Evaluate the solid, cystic, and hemorrhagic components of lesions
• Evaluate vascularity of the brain and vascular integrity
• Monitor and evaluate the effectiveness of medical or surgical interventions, chemotherapy, radiation therapy, and the course of disease

RESULT:

Normal findings in:
• Normal anatomic structures, soft tissue density, blood flow rate, face, nasopharynx, neck, tongue, and brain

Abnormal findings in:
• Abscess
• Acoustic neuroma
• Alzheimer’s disease
• Aneurysm
• Arteriovenous malformation
• Benign meningioma
• Cerebral aneurysm
• Cerebral infarction
• Craniopharyngioma or meningioma
• Granuloma
• Intraparenchymal hematoma or hemorrhage
• Lipoma
• Metastasis
• Multiple sclerosis
• Optic nerve tumor
• Parkinson’s disease
• Pituitary microadenoma
• Subdural empyema
• Ventriculitis

CRITICAL VALUES:
• Abcess
• Cerebral aneurysm
• Cerebral infarct
• Hydrocephalus
• Skull fracture or contusion
• Tumor with significant mass effect

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
• Patients with metal in their body, such as shrapnel or ferrous metal in the eye
• Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
• Use of gadolinium-based contrast agents (GBCA) is contraindicated in patients with acute or chronic severe renal insufficiency (glomerular filtration rate less than 30 mL/min/1.73 m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non–contrast-enhanced diagnostic studies.
• Patients with intrauterine devices
• Patients with iron pigments in tattoos
• Patients who are claustrophobic
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
• Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized

Access additional resources at davisplus.fadavis.com
**Other considerations:**
- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the brain.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- Obtain a history of results of the patient’s cardiovascular and endocrine systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.
- Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in an MRI department, usually by a health care provider (HCP) who specializes in this procedures, with support staff, and takes approximately 30 to 60 min.
- Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives.
- Instruct the patient to remove jewelry and all other metallic objects from the area to be examined prior to the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
Supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.

If an electrocardiogram or respiratory gating is to be performed in conjunction with the scan, apply MRI-safe electrodes to the appropriate sites.

Establish an IV fluid line for the injection of emergency drugs and sedatives.

Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

Place the patient in the supine position on an exam table.

If contrast is used, imaging can begin shortly after the injection.

Ask the patient to inhale deeply and hold his or her breathe while the images are taken, and then to exhale after the images are taken.

Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

Remove the needle or catheter and apply a pressure dressing over the puncture site.

POST-TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting, if contrast medium was used.

Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.

Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include Alzheimer disease markers, angiography of the carotids, BUN, CSF analysis, CT brain, creatinine, EMG, evoked brain potentials, and PET brain.

Refer to the Cardiovascular and Endocrine System tables at the back of the book for related tests by body system.

SYNONYM/ACRONYM: Breast MRI.

AREA OF APPLICATION: Breast area.

CONTRAST: Can be done with or without IV contrast medium (gadolinium).

Access additional resources at davisplus.fadavis.com
DESCRIPTION: Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radiofrequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position; this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of the pathological lesions in multiple planes without the use of ionizing radiation or the interference of surrounding tissue, breast implants, or surgically implanted clips.

MRI imaging of the breast is not a replacement for traditional mammography, ultrasound, or biopsy. This exam is extremely helpful in evaluating mammogram abnormalities and identifying early breast cancer in women at high risk. High-risk women include those who have had breast cancer, have an abnormal mutated breast cancer gene (BRCA1 or BRCA2), or have a mother or sister who has been diagnosed with breast cancer. Breast MRI is used most commonly in high-risk women when findings of a mammogram or ultrasound are inconclusive because of dense breast tissue or there is a suspected abnormality that requires further evaluation. MRI is also an excellent exam in the augmented breast, including both the breast implant itself and the breast tissue surrounding the implant. This same exam is also useful for staging breast cancer and determining the most appropriate treatment. MRI uses the noniodinated contrast medium gadopentetate dimeglumine (Magnevist), which is administered IV to enhance contrast differences between normal and abnormal tissues.

INDICATIONS:
- Evaluate breast implants
- Evaluate dense breasts
- Evaluate for residual cancer after lumpectomy
- Evaluate inverted nipples
- Evaluate small abnormalities
- Evaluate tissue after lumpectomy or mastectomy
- Evaluate women at high risk for breast cancer

RESULT:
Normal findings in:
- Normal anatomic structures, soft tissue density, and blood flow rate

Abnormal findings in:
- Breast abscess or cyst
- Breast cancer
- Breast implant rupture
- Hematoma
- Soft tissue masses
- Vascular abnormalities

CRITICAL VALUES: N/A

INTERFERING FACTORS:
This procedure is contraindicated for:
- Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
- Patients with metal in their body, such as shrapnel or ferrous metal in the eye
• Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
• Use of gadolinium-based contrast agents (GBCA) is contraindicated in patients with acute or chronic severe renal insufficiency (glomerular filtration rate less than 30 mL/min/1.73 m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non–contrast-enhanced diagnostic studies.
• Patients with intrauterine devices
• Patients with iron pigments in tattoos
• Patients who are claustrophobic
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized

Other considerations:
• If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.
• The procedure can be nonspecific; the exam is unable to image calcifications that can indicate breast cancer, and there may be difficulty distinguishing between cancerous and noncancerous tumors.

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses the breast.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
• Obtain a history of results of the patient’s reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.
• Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
• Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
• Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
• Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in an MRI department by a health care provider (HCP) who specializes in this
procedure, with support staff, and takes approximately 30 to 60 min.
Inform the patient that the technologist will place him or her in a prone position on a special imaging table in a large cylindrical scanner.
Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives.
Instruct the patient to remove jewelry and all other metallic objects from the area to be examined prior to the procedure.
There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
Have emergency equipment readily available.
Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
Observe standard precautions, and follow the general guidelines in Appendix A.
Supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.

Establish an IV fluid line for the injection of emergency drugs and of sedatives.
Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
Place the patient in the prone position on a special exam table designed for breast imaging.
If contrast is used, imaging can begin shortly after the injection.
Ask the patient to inhale deeply and hold his or her breathe while the images are taken, and then to exhale after the images are taken.
Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
Remove the needle or catheter and apply a pressure dressing over the puncture site.

**POST-TEST:**
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnnea, hypertension, palpitations, nausea, or vomiting.
Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
Instruct the patient in the care and assessment of the injection site.
Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include biopsy breast, bone scan, BUN, cancer antigens, CT thorax, creatinine, mammogram, stereotactic biopsy breast, and US breast.
- Refer to the Reproductive System table at the back of the book for related tests by body system.

**MAGNETIC RESONANCE IMAGING, CHEST**

**SYNONYM/ACRONYM:** Chest MRI.

**AREA OF APPLICATION:** Chest/thorax.

**CONTRAST:** Can be done with or without IV contrast medium (gadolinium).

**DESCRIPTION:** Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radiofrequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position; this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of pathological lesions in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue.

Chest MRI scanning is performed to assist in diagnosing abnormalities of cardiovascular and pulmonary structures. Two special techniques are available for evaluation of cardiovascular structures. One is the electrocardiograph (ECG)-gated multislice spin-echo sequence, used to diagnose anatomic abnormalities of the heart and aorta, and the other is the ECG-referenced gradient refocused sequence, used to diagnose heart function and analyze blood flow patterns.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography (see monograph titled “Magnetic Resonance Angiography”).

Access additional resources at davisplus.fadavis.com
INDICATIONS:
• Confirm diagnosis of cardiac and pericardiac masses
• Detect aortic aneurysms
• Detect myocardial infarction and cardiac muscle ischemia
• Detect pericardial abnormalities
• Detect pleural effusion
• Detect thoracic aortic diseases
• Determine blood, fluid, or fat accumulation in tissues, pleuritic space, or vessels
• Determine cardiac ventricular function
• Differentiate aortic aneurysms from tumors near the aorta
• Evaluate cardiac chambers and pulmonary vessels
• Evaluate postoperative angioplasty sites and bypass grafts
• Identify congenital heart diseases
• Monitor and evaluate the effectiveness of medical or surgical therapeutic regimen

RESULT:
Normal findings in:
• Normal heart and lung structures, soft tissue, and function, including blood flow rate

Abnormal findings in:
• Aortic dissection
• Congenital heart diseases, including pulmonary atresia, aortic coarctation, agenesis of the pulmonary artery, and transposition of the great vessels
• Constrictive pericarditis
• Intramural and periaortic hematoma
• Myocardial infarction
• Pericardial hematoma or effusion
• Pleural effusion

CRITICAL VALUES:
• Aortic aneurysm
• Aortic dissection
• Tumor with significant mass effect

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

INTERFERING FACTORS:
This procedure is contraindicated for:
• Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
• Patients with metal in their body, such as shrapnel or ferrous metal in the eye
• Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
• Use of gadolinium-based contrast agents (GBCA) is contraindicated in patients with acute or chronic severe renal insufficiency (glomerular filtration rate less than 30 mL/min/1.73 m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non–contrast-enhanced diagnostic studies.

• Patients with intrauterine devices
• Patients with iron pigments in tattoos
• Patients who are claustrophobic
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
• Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized
Other considerations:
• If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the organs and structures inside the chest.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- Obtain a history of the patient’s cardiovascular and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a history of renal dysfunction if the use of GBCA is anticipated.
- Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- Record the date of the last menstrual period and determine possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in an MRI department, usually by a health care provider (HCP) who specializes in these procedures, with support staff, and takes approximately 30 to 60 min.
- Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Examine that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives.
- Instruct the patient to remove jewelry and all other metallic objects from the area to be examined prior to the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRA.TEST:
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.

If an electrocardiogram or respiratory gating is to be performed in conjunction with the scan, apply MRI-safe electrodes to the appropriate sites.

Establish an IV fluid line for the injection of emergency drugs and of sedatives.

Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

Place the patient in the supine position on an exam table.

If contrast is used, imaging can begin shortly after the injection.

Ask the patient to inhale deeply and hold his or her breathe while the images are taken and then to exhale after the images are taken.

Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

Remove the needle or catheter and apply a pressure dressing over the puncture site.

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include AST, BNP, blood gases, blood pool imaging, BUN, chest x-ray, CT cardiac scoring, CT thorax, CRP, CK and isoenzymes, creatinine, echocardiography, exercise stress test, Holter monitor, myocardial infarct scan, myocardial perfusion heart scan, myoglobin, pleural fluid analysis, PET scan of the heart, and troponins.

- Refer to the Cardiovascular and Respiratory System tables at the back of the book for related tests by body system.
SYNONYM/ACRONYM: Musculoskeletal (knee, shoulder, hand, wrist, foot, elbow, hip) MRI.

AREA OF APPLICATION: Bones, joints, soft tissues.

CONTRAST: Can be done with or without IV contrast medium (gadolinium).

DESCRIPTION: Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radiofrequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position; this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of bones and joints in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue.

Musculoskeletal MRI is performed to assist in diagnosing abnormalities of bones and joints and surrounding soft tissue structures, including cartilage, synovium, ligaments, and tendons. MRI eliminates the risks associated with exposure to x-rays and causes no harm to cells. Contrast-enhanced imaging is effective for evaluating scarring from previous surgery, vascular abnormalities, and differentiation of metastases from primary tumors. MRI uses the noniodinated contrast medium gadopentetate dimeglumine (Magnevist), which is administered IV to enhance contrast differences between normal and abnormal tissues.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography (see monograph titled “Magnetic Resonance Angiography”).

INDICATIONS:
- Confirm diagnosis of osteomyelitis
- Detect avascular necrosis of the femoral head or knee
- Detect benign and cancerous tumors and cysts of the bone or soft tissue
- Detect bone infarcts in the epiphyseal or diaphyseal sites
- Detect changes in bone marrow

Access additional resources at davisplus.fadavis.com
• Detect tears or degeneration of ligaments, tendons, and menisci resulting from trauma or pathology
• Determine cause of low back pain, including herniated disk and spinal degenerative disease
• Differentiate between primary and secondary malignant processes of the bone marrow
• Differentiate between a stress fracture and a tumor
• Evaluate meniscal detachment of the temporomandibular joint

RESULT:

Normal findings in:
• Normal bones, joints, and surrounding tissue structures; no articular disease, bone marrow disorders, tumors, infections, or trauma to the bones, joints, or muscles

Abnormal findings in:
• Avascular necrosis of femoral head or knee, as found in Legg-Calvé-Perthes disease
• Bone marrow disease, such as Gaucher’s disease, aplastic anemia, sickle cell disease, or polycythemia
• Degenerative spinal disease, such as spondylosis or arthritis
• Fibrosarcoma
• Hemangioma (muscular or osseous)
• Herniated disk
• Infection
• Meniscal tears or degeneration
• Osteochondroma
• Osteogenic sarcoma
• Osteomyelitis
• Rotator cuff tears
• Spinal stenosis
• Stress fracture
• Synovitis
• Tumor

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
• Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
• Use of gadolinium-based contrast agents (GBCA) is contraindicated in patients with acute or chronic severe renal insufficiency (glomerular filtration rate less than 30 mL/min/1.73m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non–contrast-enhanced diagnostic studies.
• Patients with metal in their body, such as shrapnel or ferrous metal in the eye
• Patients with intrauterine devices
• Patients with iron pigments in tattoos
• Patients who are claustrophobic
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

This procedure is contraindicated for:
• Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized

Other considerations:
• If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.
**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses muscles, bones, and joints.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- Obtain a history of results of the patient’s cardiovascular and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.
- Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in an MRI department, usually by a health care provider (HCP) specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives.
- Instruct the patient to remove jewelry, and all other metallic objects from the area to be examined prior to the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
Observe standard precautions, and follow the general guidelines in Appendix A.
Supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.
Establish an IV fluid line for the injection of emergency drugs and of sedatives.
Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
Place the patient in the supine position on an exam table.
If contrast is used, imaging can begin shortly after the injection.
Ask the patient to inhale deeply and hold his or her breathe while the images are taken, and then to exhale after the images are taken.
Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
Remove the needle or catheter and apply a pressure dressing over the puncture site.

POST-TEST:
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting, if contrast medium was used.
Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
Instruct the patient in the care and assessment of the injection site.
Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
Related tests include anticyclic citrullinated antibodies, ANA, arthrogram, arthroscopy, bone mineral densitometry, bone scan, BUN, CRP, CT spine, creatinine, ESR, radiography of the bone, synovial fluid analysis, RF, and vertebroblasty.
Refer to the Cardiovascular and Musculoskeletal System tables at the back of the book for related tests by body system.
Magnetic Resonance Imaging, Pancreas

SYNONYM/ACRONYM: Pancreatic MRI.

AREA OF APPLICATION: Pancreatic/upper abdominal area.

CONTRAST: Can be done with or without IV contrast medium (gadolinium).

DESCRIPTION: Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radiofrequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position; this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of the abdominal area in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue.

MRI of the pancreas is employed to evaluate small pancreatic adenocarcinomas, islet cell tumors, ductal abnormalities and calculi, or parenchymal abnormalities. A T1-weighted, fat-saturation series of images is probably best for evaluating the pancreatic parenchyma. This sequence is ideal for showing fat planes between the pancreas and peripancreatic structures and for identifying abnormalities, such as fatty infiltration of the pancreas, hemorrhage, adenopathy, and carcinomas. T2-weighted images are most useful for depicting intrapancreatic or peripancreatic fluid collections, pancreatic neoplasms, and calculi. Imaging sequences can be adjusted to display fluid in the biliary tree and pancreatic ducts. MRI uses the noniodinated contrast medium gadopentetate dimeglumine (Magnevist), which is administered IV to enhance contrast differences between normal and abnormal tissues.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography (see monograph titled “Magnetic Resonance Angiography”).

INDICATIONS:
- Detect pancreatic fatty infiltration, hemorrhage, and adenopathy
- Detect a pancreatic mass
- Detect pancreatitis
- Detect primary or metastatic tumors of the pancreas and provide cancer staging

Access additional resources at davisplus.fadavis.com
• Detect soft tissue abnormalities
• Determine vascular complications of pancreatitis, venous thrombosis, or pseudoaneurysm
• Differentiate tumors from other abnormalities, such as cysts, cavernous hemangiomas, and pancreatic abscesses
• Monitor and evaluate the effectiveness of medical or surgical interventions and course of disease

RESULT:

Normal findings in:
• Normal anatomic structures and soft tissue density and biochemical constituents of the pancreatic parenchyma, including blood flow

Abnormal findings in:
• Islet cell tumor
• Metastasis
• Pancreatic duct obstruction or calculi
• Pancreatic fatty infiltration, hemorrhage, and adenopathy
• Pancreatic mass
• Pancreatitis

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
• Patients with metal in their body, such as shrapnel or ferrous metal in the eye
• Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
• Use of gadolinium-based contrast agents (GBCA) is contraindicated in patients with acute or chronic severe renal insufficiency (glomerular filtration rate less than 30 mL/min/1.73m²).

Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non–contrast-enhanced diagnostic studies.
• Patients with intrauterine devices
• Patients with iron pigments in tattoos
• Patients who are claustrophobic
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
• Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized

Other considerations:
• If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses the pancreas and the organs and structures inside the abdomen.
Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.

Obtain a history of results of the patient’s hepatobiliary and endocrine systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.

Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.

Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.

Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).

Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in an MRI department by a health care provider (HCP) specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.

Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives.

Instruct the patient to remove jewelry and all other metallic objects from the area to be examined prior to the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.

Establish an IV fluid line for the injection of emergency drugs and of sedatives.

Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

Place the patient in the supine position on an exam table.

If contrast is used, imaging can begin shortly after the injection.

Ask the patient to inhale deeply and hold his or her breathe while the images...
are taken and then to exhale after the images are taken.

- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- Remove the needle or catheter and apply a pressure dressing over the puncture site.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the injection site.
- Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.

- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
- Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include amylase, angiography of the abdomen, BUN, calcitonin, cholangiopancreatography endoscopic retrograde, CT abdomen, creatinine, hepatobiliary scan; 5-hydroxyindoleacetic acid, lipase, peritoneal fluid analysis, US liver and biliary system, and US pancreas.
- Refer to the Hepatobiliary and Endocrine System tables at the back of the book for related tests.

**Magnetic Resonance Imaging, Pelvis**

**SYNONYM/ACRONYM:** Pelvic MRI.

**AREA OF APPLICATION:** Pelvic area.

**CONTRAST:** Can be done with or without IV contrast medium (gadolinium).

**DESCRIPTION:** Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radiofrequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned...
Magnetic resonance imaging (MRI) of the pelvis is a procedure that uses a strong magnetic field and radio waves to create detailed images of internal structures. The process involves the application of a strong magnetic field to the body part being examined. As the atoms align with this magnetic field, they absorb radio waves. When the radio waves are turned off, the atoms go back to their original position; this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of the pelvic area in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue.

Pelvic MRI is performed to assist in diagnosing abnormalities of the pelvis and associated structures. Contrast-enhanced MRI is effective for evaluating metastases from primary tumors. MRI is highly effective for depicting small-volume peritoneal tumors, carcinomatosis, and peritonitis and for determining the response to surgical and chemical therapies. MRI uses the noniodinated contrast medium gadopentetate dimeglumine (Magnevist), which is administered IV to enhance contrast differences between normal and abnormal tissues. Oral and rectal contrast administration may be used to isolate the bowel from adjacent pelvic organs and improve organ visualization.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography (see monograph titled “Magnetic Resonance Angiography”).

**INDICATIONS:**
- Detect cancer (primary or metastatic tumors of ovary, prostate, uterus, and bladder) and provide cancer staging
- Detect pelvic vascular diseases
- Detect peritonitis
- Detect soft tissue abnormalities
- Determine blood clots, cysts, fluid or fat accumulation in tissues, hemorrhage, and infarctions
- Differentiate tumors from tissue abnormalities, such as cysts, cavernous hemangiomas, and abscesses
- Monitor and evaluate the effectiveness of medical or surgical interventions and course of the disease

**RESULT:**

**Normal findings in:**
- Normal pelvic structures and soft tissue density and biochemical constituents of pelvic tissues, including blood flow

**Abnormal findings in:**
- Adenomyosis
- Ascites
- Fibroids
- Masses, lesions, infections, or inflammations
- Peritoneal tumor or carcinomatosis
- Peritonitis
- Pseudomyxoma peritonei

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

This procedure is contraindicated for:
- Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
- Patients with metal in their body, such as shrapnel or ferrous metal in the eye
- Patients with cardiac pacemaker, because the pacemaker can be deactivated by MRI
- Use of gadolinium-based contrast agents (GBCA) is contraindicated in patients with acute or chronic severe renal insufficiency (glomerular filtration rate less than 30 mL/min/1.73m²).
Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non–contrast-enhanced diagnostic studies.

- Patients with intrauterine devices
- Patients with iron pigments in tattoos
- Patients who are claustrophobic
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

**Factors that may impair clear imaging:**

- Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized

**Other considerations:**

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible

### **NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the organs and structures inside the pelvis and lower abdomen.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- Obtain a history of results of the patient’s gastrointestinal and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a history of renal dysfunction if the use of GBCA is anticipated.
- Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in an MRI department by a health care provider (HCP) specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives. Instruct the patient to remove jewelry and all other metallic objects from the area to be examined prior to the procedure. There are no food, fluid, or medication restrictions, unless by medical direction.

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient. Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting. Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output. Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation. Instruct the patient in the care and assessment of the injection site. Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema. Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include BUN, CT pelvis, creatinine, cystourethography voiding, IVP, KUB study, renogram, and US pelvis. Refer to the Gastrointestinal and Genitourinary System tables at the back of the book for related tests.
Magnetic Resonance Imaging, Pituitary

SYNONYM/ACRONYM: Pituitary MRI, MRI of the perisellar region.

AREA OF APPLICATION: Brain/pituitary area.

CONTRAST: Can be done with or without IV contrast medium (gadolinium).

DESCRIPTION: Magnetic resonance imaging (MRI) uses a magnet and radio waves to produce an energy field that can be displayed as an image. Use of magnetic fields with the aid of radiofrequency energy produces images primarily based on water content of tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the atoms absorb the radio waves and change their position. When the radio waves are turned off, the atoms go back to their original position; this change in the energy field is sensed by the equipment, and an image is generated by the attached computer system. MRI produces cross-sectional images of the pituitary and perisellar region in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue.

Pituitary MRI shows the relationship of pituitary lesions to the optic chiasm and cavernous sinuses. MRI has the capability of distinguishing the solid, cystic, and hemorrhagic components of lesions. Rapidly flowing blood on spin-echo MRI appears as an absence of signal or a void in the vessel’s lumen. Blood flow can be evaluated in the cavernous and carotid arteries. Suprasellar aneurysms may be diagnosed without angiography, and old clotted blood in the walls of the aneurysms appears white. MRI uses the noniodinated contrast medium gadopentetate dimeglumine (Magnevist), which is administered IV to enhance contrast differences between normal and abnormal tissues.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography (see monograph titled “Magnetic Resonance Angiography”).

INDICATIONS:
• Detect microadenoma or macroadenoma of the pituitary
• Detect perisellar abnormalities
• Detect tumors of the pituitary
• Evaluate potential cause of headache, visual loss, and vomiting
• Evaluate the solid, cystic, and hemorrhagic components of lesions
• Evaluate vascularity of the pituitary
• Monitor and evaluate the effectiveness of medical or surgical interventions and course of disease
RESULT:

Normal findings in:
- Normal anatomic structures, density, and biochemical constituents of the pituitary, including blood flow

Abnormal findings in:
- Abscess
- Aneurysm
- Choristoma
- Craniopharyngioma or meningioma
- Empty sella
- Granuloma
- Infarct or hemorrhage
- Macroadenoma or microadenoma
- Metastasis
- Parasitic infection

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients with certain ferrous metal prostheses, valves, aneurysm clips, inner ear prostheses, or other metallic objects
- Patients with metal in their body, such as shrapnel or ferrous metal in the eye
- Patients with cardiac pacemakers, because the pacemaker can be deactivated by MRI
- Use of gadolinium-based contrast agents (GBCA) is contraindicated in patients with acute or chronic severe renal insufficiency (glomerular filtration rate less than 30 mL/min/1.73 m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non-contrast-enhanced diagnostic studies.
- Patients with intrauterine devices
- Patients with iron pigments in tattoos
- Patients who are claustrophobic
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
- Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized.

Other considerations:
- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the pituitary and surrounding brain tissue.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- Obtain a history of results of the patient’s cardiovascular and endocrine systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.
Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.

Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.

Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).

Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that no pain will be experienced during the test, but there may be moments of discomfort. Inform the patient the procedure is performed in an MRI department by a health care provider (HCP) specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.

Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives.

Instruct the patient to remove jewelry and all other metallic objects from the area to be examined prior to the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.

Establish an IV fluid line for the injection of emergency drugs and of sedatives.

Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

Place the patient in the supine position on an exam table.

If contrast is used, imaging can begin shortly after the injection.

Ask the patient to inhale deeply and hold his or her breathe while the images are taken, and then to exhale after the images are taken.

Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

Remove the needle or catheter and apply a pressure dressing over the puncture site.

POST TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
Mammography

SYNONYM/ACRONYM: Mammogram, breast x-ray.

AREA OF APPLICATION: Breast.

CONTRAST: None.

DESCRIPTION: Mammography, an x-ray examination of the breast, is most commonly used to detect breast cancer; however, it can also be used to detect and evaluate symptomatic changes associated with other breast diseases, including mastitis, abscess, cystic changes, cysts, benign tumors, masses, and lymph nodes. Mammography is usually performed with traditional x-ray film, but totally electronic image recording is becoming commonplace. Mammography can be used to locate a nonpalpable lesion for biopsy. Mammography cannot detect breast cancer with 100% accuracy. In approximately 15% of breast cancer cases, the cancer is not detected with mammography. To assist in early detection of nonpalpable breast lesions, computer-assisted diagnosis is currently being used. With this technique, a computer performs automated scanning of
the mammogram before the physician interprets the findings.

When a mass is detected, additional studies are performed to help differentiate the nature of the mass, as follows:
- Magnification views of the area in question
- Focal or “spot” views of the area in question, done with a specialized paddle-style compression device
- Ultrasound images of the area in question, which help differentiate between a fluid-filled cystic lesion and a solid lesion indicative of cancer or fibroadenomas

The American College of Physicians recommends an annual or biannual mammogram for women age 50 and older. Their guidelines, based on evidence-based studies, recommend that women between 40 and 49 yr discuss their personal risk/benefit with a health care professional (HCP) prior to mammography. Scientific evidence studied in the preparation of these guidelines indicates that breast cancer risk is not distributed evenly among women in their 40s; therefore, uniform screening of women in this age group is not supported without consideration of family history and other risk factors.

The American Cancer Society recommends that all women follow a personal breast-care plan according to age:
- **Women ages 20 to 39:** Clinical breast examination performed by a HCP every 3yr and a monthly breast self-examination
- **Women ages 40 and older:** Annual mammogram, clinical breast examination every year by a HCP (near time of the mammogram), and monthly breast self-examination.

**INDICATIONS:**
- Differentiate between benign and neoplastic breast disease
- Evaluate breast pain, skin retraction, nipple erosion, or nipple discharge
- Evaluate known or suspected breast cancer
- Evaluate nonpalpable breast masses
- Evaluate opposite breast after mastectomy
- Monitor postoperative and post–radiation treatment status of the breast
- Evaluate size, shape, and position of breast masses

**RESULT:**
- **Normal findings in:**
  - Normal breast tissue, with no cysts, tumors, or calcifications
- **Abnormal findings in:**
  - Breast calcifications
  - Breast cysts or abscesses
  - Breast tumors
  - Hematoma resulting from trauma
  - Mastitis
  - Soft-tissue masses
  - Vascular calcification

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- This procedure is contraindicated for:
  - Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
  - Patients younger than age 25, because the density of the breast tissue is such that diagnostic x-rays are of limited value

- Factors that may impair clear imaging:
  - Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
• Application of substances such as talcum powder, deodorant, or creams to the skin of breasts or underarms, which may alter test results
• Previous breast surgery, breast augmentation, or the presence of breast implants, which may decrease the readability of the examination

Other considerations:
• Consultation with a HCP should occur before the procedure for radiation safety concerns regarding infants of patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures.

Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➧ Inform the patient that the procedure assesses breast status.
➧ Obtain a history of the patient’s symptoms and complaints.
➧ Obtain a history of known or suspected breast disease, and family history of breast disease.
➧ Obtain a history of results of previously performed breast biopsies and surgical procedures.
➧ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Address concerns about pain related to the procedure. Inform the patient there may be discomfort associated with the study, while the breast is being compressed, but that the compression allows for better visualization of the breast tissue. Explain to the patient that the radiation dose will be kept to an absolute minimum. Inform the patient that the procedure is performed in the mammography department by a registered mammographer and takes approximately 15 to 30 min to complete.

Inform the patient that the best time to schedule the examination is 1 wk after menses, when breast tenderness is decreased.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during and after the procedure.

Inform the patient not to apply deodorant, body creams, or powders on the day of the procedure.

Instruct the patient to remove jewelry and other metallic objects from the field of examination.

There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
➧ Ensure that the patient has removed all jewelry, and other metallic objects from the chest area.
➧ Instruct the patient to void prior to the procedure and to change into the gown and robe provided.
➧ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
➧ Observe standard precautions and follow the general guidelines in Appendix A.
➧ Assist the patient to a standing or sitting position in front of the x-ray machine, which is adjusted to the level of the breasts. Position the patient’s arms out of the range of the area to be imaged.
Place breasts, one at a time, between the compression apparatus. Two views or exposures are taken of each breast. Ask the patient to hold her breathe during each exposure. Additional images may be taken as requested by the radiologist before the patient leaves the mammography room.

POST-TEST:

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Determine if the patient has any further questions or concerns.
- Educate the patient regarding the techniques for breast self-examination.
- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Cancer Society (www.cancer.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient.

Instruct and educate the patient how to perform monthly breast self-examination and emphasize, as appropriate, the importance of having a mammogram performed as indicated through discussion with her HCP and in keeping with the current standard of care. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELEVANT MONOGRAPHS:

- Related tests include biopsy breast, cancer antigens, MRI breast, stereotactic biopsy breast, and US breast.
- Refer to the Reproductive System table at the back of the book for related tests by body system.

Meckel’s Diverticulum Scan

SYNONYM/ACRONYM: Meckel’s scan, Meckel’s scintigraphy, ectopic gastric mucosa scan.

AREA OF APPLICATION: Abdomen.

CONTRAST: IV radioactive technetium-99m pertechnetate.

DESCRIPTION: Meckel’s diverticulum scan is a nuclear medicine study performed to assist in diagnosing the cause of abdominal pain or occult gastrointestinal (GI) bleeding, and to assess the presence and size of a congenital anomaly of the GI tract. After IV injection of technetium-99m pertechnetate, immediate and delayed imaging is performed, with various views of the abdomen obtained. The radionuclide is taken up and
concentrated by parietal cells of the gastric mucosa, whether located in the stomach or in a Meckel’s diverticulum. Up to 25% of Meckel’s diverticulum is lined internally with ectopic gastric mucosal tissue. This tissue is usually located in the ileum and right lower quadrant of the abdomen; it secretes acid that causes ulceration of intestinal tissue, which results in abdominal pain and occult blood in stools.

**INDICATIONS:**
- Aid in the diagnosis of unexplained abdominal pain and GI bleeding caused by hydrochloric acid and pepsin secreted by ectopic gastric mucosa, which ulcerates nearby mucosa
- Detect sites of ectopic gastric mucosa

**RESULT:**
**Normal findings in:**
- Normal distribution of radionuclide by gastric mucosa at normal sites

**Abnormal findings in:**
- Meckel’s diverticulum, as evidenced by focally increased radioactive uptake in areas other than normal structures

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

**This procedure is contraindicated for:**
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

**Factors that may impair clear imaging:**
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Retained barium from a previous radiological procedure
- Other nuclear scans done within the preceding 24 hr

**Other considerations:**
- Improper injection of the radionuclide may allow the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- False-positive results may occur from nondiverticular bleeding, intussusception, duplication cysts, inflammatory bowel disease, hemangioma of the bowel, and other organ infections.
- Inadequate amount of gastric mucosa within Meckel’s diverticulum can affect the ability to visualize abnormalities.
- Inaccurate timing for imaging after the radionuclide injection can affect the results.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses GI bleeding.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- Obtain a history of the patient’s cardiovascular and GI systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.

INTRATEST:

- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- Instruct the patient to take a histamine blocker, as ordered, 2 days before the study to block GI secretion.
- The patient should fast and refrain from fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
POST-TEST:

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- Instruct the patient to resume usual diet, fluids, and medications, as directed by the HCP.
- Monitor vital signs and neurological status every 15 minutes for 1 hour, then every 2 hr for 4 hr, and then as ordered by the HCP. Compare with baseline values. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the injection site. Observe for bleeding, hematoma formation, and inflammation.
- If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- Instruct the patient to immediately flush the toilet, and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.

Nutritional considerations: A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes. High fat consumption increases the amount of bile acids in the colon and should be avoided.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include barium swallow, colonoscopy, CT abdomen, CT pelvis, esophageal manometry, EGD, fecal analysis, gastric acid stimulation, gastric emptying scan, gastrin stimulation, GI blood loss, MRI abdomen, MRI pelvis, and upper GI series.
- Refer to the Gastrointestinal and Cardiovascular System tables in the back of the book for related tests by body system.

Mediastinoscopy

**SYNONYM/ACRONYM:** N/A.

**AREA OF APPLICATION:** Mediastinum.

**CONTRAST:** None.

**DESCRIPTION:** Mediastinoscopy provides direct visualization of the structures that lie beneath the mediastinum, which is the area behind the sternum and between the lungs. The test is performed under general anesthesia by means of a mediastinoscope inserted through a surgical incision at the suprasternal notch. Structures that can be viewed include the trachea, the esophagus, the heart and its major vessels, the thymus gland, and the lymph nodes that receive drainage from the lungs. The procedure is performed primarily to visualize and obtain biopsy specimens of the mediastinal lymph nodes, and to determine the extent of metastasis into the mediastinum for the determination of treatment planning in cancer patients.

**INDICATIONS:**
- Confirm radiological evidence of a thoracic infectious process of an indeterminate nature, coccidiodomycosis, or histoplasmosis
- Confirm radiological or cytological evidence of carcinoma or sarcoidosis
- Detect Hodgkin’s disease
- Detect metastasis into the anterior mediastinum or extrapleurally into the chest
- Determine stage of known bronchogenic carcinoma, as indicated by the extent of mediastinal lymph node involvement
- Evaluate a patient with signs and symptoms of obstruction of mediastinal lymph flow and a history of head or neck cancer to determine recurrence or spread

**RESULT:**

**Normal findings in:**
- Normal appearance of mediastinal structures
- No abnormal lymph node tissue

**Abnormal findings in:**
- Bronchogenic carcinoma
- Coccidiodomycosis
- Granulomatous infections
- Histoplasmosis
- Hodgkin’s disease
- *Pneumocystis carinii* infection
- Sarcoidosis
- Tuberculosis

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

*This procedure is contraindicated for:*
- Patients who have had a previous mediastinoscopy, because scarring can make insertion of the scope and biopsy of lymph nodes difficult
- Patients who have superior vena cava obstruction, because this condition causes increased venous collateral circulation in the mediastinum
- Patients who are pregnant or suspected of being pregnant, unless
the potential benefits of the procedure far outweigh the risks to the fetus and mother.

**Other considerations:**
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**Nursing Implications and Procedure**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient the procedure assesses the mediastinum.
- Obtain a history of the patient’s complaints or symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, and anesthetics.
- Obtain a history of the patient’s immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Ensure that the results of blood typing and cross-matching are obtained and recorded before the procedure in the event that an emergency thoracotomy is required.
- Note any recent procedures that can interfere with test results. Ensure that this procedure is performed before an upper gastrointestinal study or barium swallow.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain related to the procedure and explain that a general anesthesia will be administered to promote relaxation and reduce discomfort prior to the mediastinoscopy. Explain to the patient that some pain may be experienced after the test. Meperidine (Demerol) or morphine may be given as a sedative. Inform the patient that the procedure is performed in the operating room by a health care provider (HCP) specializing in this procedure, with support staff, and usually takes 30 to 60 min to complete.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- Instruct the patient to remove jewelry and external metallic objects from the area to be examined prior to the procedure.
- The patient should fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant.
- **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

**INTRATEST:**
- Ensure that the patient has complied with food, fluids, and medication restrictions for 8 hr prior to the procedure.
- Ensure that the patient has removed jewelry and external metallic objects from the area to be examined prior to the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and change into the gown, robe, and foot coverings provided.
- Record baseline vital signs and assess neurological status. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Establish IV fluid line for the injection of emergency drugs and of sedatives.

Access additional resources at davisplus.fadavis.com
Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias. Avoid using morphine sulfate in patients with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.

Place the patient in the supine position. General anesthesia is administered via an endotracheal tube.

An incision is made at the suprasternal notch, and a path for the mediastinoscope is made using finger dissection. The lymph nodes can be palpated at this time. The lymph nodes on the right side of the mediastinum are most accessible and safest to biopsy by mediastinoscopy; the lymph nodes on the left side are more difficult to explore and biopsy because of their proximity to the aorta. Biopsy specimens of nodes on the left side of the mediastinum may need to be obtained by mediastinotomy, which involves performing a left anterior thoracotomy.

Place tissue samples in properly labeled specimen containers, and promptly transport the specimen to the laboratory for processing and analysis.

The scope is removed, and the incision is closed.

If the patient is stable and if no further surgery is immediately indicated, the patient is extubated.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- The patient should remain in a semi-Fowler’s position on either side until vital signs revert to preprocedure levels.
- Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature changes. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Do not allow the patient to eat or drink for 12 to 24 hr.
- Instruct the patient to resume normal activity, medication, and diet in 24 hr or as tolerated after the examination, unless otherwise indicated.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Instruct the patient in the care and assessment of the site. Observe the site for bleeding, hematoma formation, and inflammation. Note any pleuritic pain, persistent right shoulder pain, or chest pain.
- Emphasize that any excessive bleeding, difficulty breathing, excessive coughing after biopsy, or pain must be reported to the HCP immediately.

**Nutritional considerations:** A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.

- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ACE, β₂-microglobulin, biopsy liver, biopsy lung, biopsy lymph node, blood gases, bronchoscopy, carbon dioxide, chest x-ray, complete blood count, complete blood count, WBC count and different-
Metanephrines

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Urine (25 mL) from a timed specimen collected in a clean amber plastic collection container with 6N hydrochloride as a preservative.

**DESCRIPTION:** Metanephrines are the inactive metabolites of epinephrine and norepinephrine. Metanephrines are either excreted or further metabolized into vanillylmandelic acid. Release of metanephrines in the urine is indicative of disorders.

Additional resources: Access additional resources at davisplus.fadavis.com
associated with excessive catecholamine production, particularly pheochromocytoma. Vanillylmandelic acid and catecholamines are normally measured with urinary metanephrines. Creatinine is usually measured simultaneously to ensure adequate collection and to calculate an excretion ratio of metabolite to creatinine.

**INDICATIONS:**
- Assist in the diagnosis of suspected pheochromocytoma
- Assist in identifying the cause of hypertension
- Verify suspected tumors associated with excessive catecholamine secretion

**RESULT:**
**Increased in:**
- Ganglioneuroma
- Neuroblastoma
- Pheochromocytoma
- Severe stress

**Decreased in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase metanephrine levels include labetalol, monoamine oxidase inhibitors, oxprenolol, oxytetracycline, and prochlorperazine.
- Methylglucamine in x-ray contrast medium may cause false-negative results.
- All urine voided for the timed collection period must be included in the collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of pheochromocytoma, neuroblastoma, and ganglioblastoma.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.
- Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may
have been discarded, thus invalidating the test.

- **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to avoid excessive exercise and stress during the 24-hr collection of urine.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

- Ensure that the patient has complied with activity restrictions during the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

**Timed Specimen:**

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container’s label the amount of urine and test start and stop times.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume usual activity, as directed by the HCP.
- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include angioigraphy adrenal, CEA, catecholamines, CT renal, HVA, renin, and VMA.
- Refer to the Endocrine System table at the back of the book for related tests by body system.
Methemoglobin

*Percentage of total hemoglobin = 0.41–1.15%.
Note: The conversion factor of ×155 is based on the molecular weight of hemoglobin of 64,500 daltons (d), or 64.5 kd.

DESCRIPTION: Methemoglobin is a structural hemoglobin variant formed when the heme portion of the deoxygenated hemoglobin is oxidized to a ferric state that renders it incapable of combining with and transporting oxygen to tissues. Visible cyanosis can result as levels approach 10% to 15% of total hemoglobin.

- Carbon monoxide poisoning (Carbon monoxide is a form of deoxygenated hemoglobin)
- Hereditary methemoglobinemia (Deficiency of NADH-methemoglobin reductase or hemoglobinopathy)

Decreased in: N/A

CRITICAL VALUES:
- Cyanosis can occur at levels greater than 10%.
- Dizziness, fatigue, headache, and tachycardia can occur at levels greater than 30%.
- Signs of central nervous system depression can occur at levels greater than 45%.
- Death may occur at levels greater than 70%.

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms. Possible interventions include airway protection, administration of oxygen, monitoring neurological status every hour, continuous pulse oximetry, hyperbaric oxygen therapy, and exchange transfusion. Administration of activated charcoal or gastric lavage

INDICATIONS:
- Assist in the detection of acquired methemoglobinemia caused by the toxic effects of chemicals and drugs
- Assist in the detection of congenital methemoglobinemia, indicated by deficiency of red blood cell nicotinamide adenine dinucleotide (NADH)-methemoglobin reductase or presence of methemoglobin.
- Evaluate cyanosis in the presence of normal blood gases

RESULT:

Increased in:
- Acquired methemoglobinemia (drugs, tobacco smoking, or ionizing radiation)

Conventional Units SI Units (Conventional Units × 155)
0.06–0.24 g/dL* 9.3–37.2 micromol/L*
may be effective if performed soon after the toxic agent is ingested. Emesis should never be induced in patients with no gag reflex because of the risk of aspiration. Methylene blue may be used to reverse the process of methemoglobin formation, but it should be used cautiously when methemoglobin levels are greater than 30%. Use of methylene blue is contraindicated in the presence of glucose-6-phosphate dehydrogenase deficiency.

**INTERFERING FACTORS:**
- Drugs that may increase methemoglobin levels include acetanilid, amylnitrate, aniline derivatives, benzocaine, chlorates, chloroquine, dapsone, glucosulfone, isoniazid, lidocaine, nitroglycerin, phenacetin, phenytoin, primaqaine, resorcinol, sulfonamides, and thiazolsulfone.
- Well water containing nitrate is the most common cause of methemoglobinemia in infants.
- Breastfeeding infants are capable of converting inorganic nitrate from common topical anesthetic applications containing nitrate to the nitrite ion, causing nitrite toxicity and increased methemoglobin.
- Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results. Methemoglobin is unstable and should be transported on ice within a few hours of collection, or else the specimen should be rejected.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to investigate cyanosis associated with polycythemia, hemoglobinopathies, and drug toxicity (inhaled substances).
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- Prepare an ice slurry in a cup or plastic bag to have on hand for immediate transport of the specimen to the laboratory.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.
The specimen should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Teach the patient to avoid carbon monoxide from first- or second-hand smoking, to have home gas furnace checked yearly for leaks, and to utilize gas appliances such as gas grills in a well-ventilated area.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.

**RELATED MONOGRAPHS:**

- Related tests include alveolar/arterial gradient, blood gases, carboxyhemoglobin, hemoglobin electrophoresis, and pulse oximetry.
- Refer to the Hematopoietic and Respiratory System tables at the back of the book for related tests by body system.

---

**Microalbumin**

**SYNONYM/ACRONYM:** Albumin, urine.

**SPECIMEN:** Urine (10 mL) from a random or timed specimen collected in a clean plastic collection container.

**REFERENCE VALUE:** (Method: Nephelometry immunoassay)

<table>
<thead>
<tr>

Simultaneous measurement of urine creatinine or creatinine clearance may be requested. Normal ratio of microalbumin to creatinine is less than 30:1.

**DESCRIPTION:** The term *microalbumin* is used to describe concentrations of albumin in urine that are greater than normal but undetectable by dipstick or traditional spectrophotometry methods. Microalbuminuria precedes the nephropathy associated with diabetes and is often elevated years before creatinine...
A clearance shows abnormal values. Studies have shown that the median duration from onset of microalbuminuria to development of nephropathy is 5 to 7 yr.

**INDICATIONS:**
- Evaluate renal disease
- Screen diabetic patients for early signs of nephropathy

**RESULT:**

*Increased in:*
- Conditions resulting in increased renal excretion or loss of protein.
  - Cardiomyopathy
  - Diabetic nephropathy
  - Exercise
  - Hypertension (uncontrolled)
  - Pre-eclampsia
  - Renal disease
  - Urinary tract infections

*Decreased in:* N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may decrease microalbumin levels include captopril, dipyridamole, enalapril, furosemide, indapamide, perindopril, quinapril, ramipril, tolrestat, and triflusal.
- All urine voided for the timed collection period must be included in the collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

**INTRATEST:**
- Inform the patient that the test is used to assist in the management of early diabetes in order to avoid or delay the onset of renal disease associated with diabetes.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine and genitourinary systems, symptoms, and results of previously performed laboratory tests, diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.
- Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to avoid excessive exercise and stress during the 24-hour collection of urine.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Access additional resources at davisplus.fadavis.com
If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

**Random Specimen (Collect in Early Morning):**
- **Clean-Catch Specimen:**
  - Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
  - Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

- **Indwelling Catheter:**
  - Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 minutes before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

- **Timed Specimen:**
  - Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
  - Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.

If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container’s label the amount of urine and test start and stop times.

**General:**
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP) who will discuss the results with the patient.
- Instruct the patient to resume usual activity, as directed by the HCP.
- Instruct the patient and caregiver to report signs and symptoms of hypoglycemia or hyperglycemia.

**Nutritional considerations:** Instruct the patient, as appropriate, in nutritional management of diabetes. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. There is no “diabetic diet”; however, there are many meal-planning approaches with nutritional goals endorsed by the American Dietetic Association. The nutritional needs of each diabetic patient need to be determined individually with the appropriate health care professionals, particularly professionals trained in nutrition.
- Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching
and information regarding the clinical implications of the test results, as appropriate. Emphasize, if indicated, that good glycemic control delays the onset and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services, as appropriate. Provide contact information, if desired, for the American Diabetes Association (www.diabetes.org).

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include A/G ratio, angiography renal, blood pool imaging, BUN, complete blood count, cortisol, creatinine, creatinine clearance, culture urine, cystometry, cystoscopy, cytology urine, echocardiography, echocardiography transesophageal, EPO, fluorescein angiography, fundus photography, glucose, GTT, glycated hemoglobin, gonioscopy, holter monitor, insulin, insulin antibodies, magnesium, protein total and fractions, renogram, UA, visual fields test, and voiding cystourethrography.

- Refer to the Endocrine and Genitourinary System tables at the back of the book for related tests by body system.

---

**β₂-Microglobulin**

**SYNONYM/ACRONYM:** β₂-M, BMG.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube or 5 mL urine from a timed collection in a clean plastic container with 1N NaOH as a preservative.

**REFERENCE VALUE:** (Method: Immunoassay for serum sample, radioimmunoassay for urine sample)

<table>
<thead>
<tr>
<th>Sample</th>
<th>Conventional Units</th>
<th>SI Units (Conventional Units × 10)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Serum</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Newborn</td>
<td>Less than 0.3 mg/dL</td>
<td>Less than 3 mg/L</td>
</tr>
<tr>
<td>Adult</td>

<td>Less than 2 mg/L</td>
</tr>
<tr>
<td>Urine</td>
<td>0.03–0.37 mg/24 h</td>
<td></td>
</tr>
</tbody>
</table>

**DESCRIPTION:** β₂-Microglobulin (BMG) is an amino acid peptide component of human leukocyte antigen (HLA) complexes. BMG increases in inflammatory conditions and when lymphocyte turnover increases, such as in lymphocytic leukemia or when T-lymphocyte helper (OKT4) cells are attacked by.

Access additional resources at davisplus.fadavis.com
HIV. Serum BMG becomes elevated with malfunctioning glomeruli, but decreases with malfunctioning tubules because it is metabolized by the renal tubules. Conversely, urine BMG decreases with malfunctioning glomeruli, but becomes elevated with malfunctioning tubules.

**INDICATIONS:**
- Detect aminoglycoside toxicity
- Detect chronic lymphocytic leukemia, multiple myeloma, lung cancer, hepatoma, or breast cancer
- Detect HIV infection (note: levels do not correlate with stages of infection)
- Evaluate renal disease to differentiate glomerular from tubular dysfunction
- Monitor antiretroviral therapy

**RESULT:**
**Increased in:**
- AIDS (Related to increased lymphocyte turnover)
- Aminoglycoside toxicity (Urine BMG becomes elevated before creatinine indicates renal damage)
- Amyloidosis (Chronic inflammatory conditions are associated with increased BMG and other acute phase reactant proteins)
- Autoimmune disorders (Related to increased lymphocyte turnover)
- Breast cancer (Related to increased lymphocyte turnover; serum BMG indicates tumor growth rate, size, and response to treatment)
- Crohn's disease (Chronic inflammatory conditions are associated with increased BMG and other acute phase reactant proteins)
- Felty's syndrome (Chronic inflammatory conditions are associated with increased BMG and other acute phase reactant proteins)
• Vasculitis (Chronic inflammatory conditions are associated with increased BMG and other acute phase reactant proteins)
• Viral infections (e.g., cytomegalovirus) (Related to increased lymphocyte turnover)

Decreased in:
• Renal disease (glomerular): urine only
• Renal disease (tubular): serum only
• Response to zidovudine (AZT) (Related to decreased viral replication and lymphocyte destruction)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs and proteins that may increase serum BMG levels include cefuroxime, cyclosporin A, gentamicin, interferon alfa, pentoxifylline, and tumor necrosis factor.
• Drugs that may decrease serum BMG levels include zidovudine.
• Drugs that may increase urine BMG levels include azathioprine, cisplatin, cyclosporin A, furosemide, gentamicin, mannitol, nifedipine, sisomicin, and tobramycin.
• Drugs that may decrease urine BMG levels include cilostazol.
• Urinary BMG is unstable at pH less than 5.5.
• Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when radioimmunoassay is the test method.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
➢ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➢ Inform the patient that the test is used to evaluate renal disease, AIDS, and certain malignancies.
➢ Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
➢ Obtain a history of the patient’s genitourinary and immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
➢ Note any recent procedures that can interfere with test results.
➢ Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
➢ Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
➢ There are no food, fluid, or medication restrictions, unless by medical direction.

Blood:
➢ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Urine:
➢ Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device.
➢ Usually a 24-hr urine collection is ordered. Inform the patient that all urine over a 24-hr period must be saved; instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom as a reminder to save all urine.
➢ Instruct the patient to void all urine into the collection device and then pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

INTRATEST:
➢ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to
avoid unnecessary movement during the venipuncture.

- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes or collection containers with the corresponding patient demographics, date, and time of collection.

**Blood:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

**Urine:**
- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- If possible, begin the test between 6 and 8 a.m. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. At the same time the next morning, ask the patient to void and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection started.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection. If the specimen contains less than what was recorded as output, some urine may have been discarded, thus invalidating the test.

**Blood or Urine:**
- Promptly transport the specimen to the laboratory for processing and analysis. Include on the urine specimen label the amount of urine and ingestion of any medications that can affect test results.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Educate the patient regarding the risk of infection related to immunosuppressed inflammatory response and fatigue related to decreased energy production.
- **Nutritional considerations:** Stress the importance of good nutrition, and suggest that the patient meet with a nutritional specialist. Also, stress the importance of following the care plan for medications and follow-up visits.
- **Social and cultural considerations:** Recognize anxiety related to test results, and be supportive of impaired activity related to weakness, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

**Social and cultural considerations:**
- Offer support, as appropriate, to patients who may be the victims of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nontaxing atmosphere for a discussion during which risks of sexually transmitted diseases are explained. It is also important to discuss problems the patient may experience (e.g., guilt, depression, anger).
Mumps Serology

SYNONYM/ACRONYM: N/A.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Indirect immunofluorescence) Negative or less than a fourfold increase in titer.

DESCRIPTION: Mumps serology is done to determine the presence of mumps antibody, indicating exposure to or active presence of mumps. Mumps, also known as parotitis, is an infectious viral disease of the parotid glands caused by a myxovirus that is transmitted by direct contact with or droplets spread from the saliva of an infected person. The incubation period averages 3 weeks. Virus can be shed in saliva for 2 weeks after infection and in urine for 2 weeks after the onset of symptoms. Complications of infection include aseptic meningitis, encephalitis, and inflammation of the testes, ovaries, and pancreas. The presence of immunoglobulin M (IgM) antibodies indicates acute infection. The presence of immunoglobulin G (IgG) antibodies indicates current or past infection.
INDICATIONS:
• Determine resistance to or protection against the mumps virus by a positive reaction, or susceptibility to mumps by a negative reaction
• Document immunity
• Evaluate mumps-like diseases and differentiate between these and actual mumps

RESULT:
• Past or current mumps infection.

CRITICAL VALUES: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE
PRETEST:
➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➧ Inform the patient that the test is used to confirm acute infection with or immunity to the mumps virus.
➧ Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex. Obtain a history of exposure.
➧ Obtain a history of the patient’s immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
➧ Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
➧ Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm diagnosis. Any individual positive result should be repeated in 7 to 14 days to monitor a change in titer. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
➧ There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
➧ If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
➧ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
➧ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
➧ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
➧ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
➧ A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
➧ Instruct the patient in isolation precautions during the time of communicability or contagion.
➧ Emphasize that the patient must return to have a convalescent blood sample taken in 7 to 14 days.
➧ Inform the patient that the presence of mumps antibodies ensures lifelong immunity.
➧ Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Provide information regarding vaccine-preventable diseases where indicated (e.g., encephalitis, Hepatitis A and B, human papillomavirus, influenza, measles, mumps, polio, rubella, smallpox, varicella, yellow fever). Answer any
Myocardial Infarct Scan

**SYNONYM/ACRONYM:** PYP cardiac scan, infarct scan, pyrophosphate cardiac scan, acute myocardial infarction scan.

**AREA OF APPLICATION:** Heart, chest/thorax.

**CONTRAST:** IV radioactive material, usually technetium-99m stannous pyrophosphate (PYP).

**DESCRIPTION:** Technetium-99m stannous pyrophosphate (PYP) scanning, also known as myocardial infarct imaging, reveals the presence of myocardial perfusion and the extent of myocardial infarction (MI). This procedure can distinguish new from old infarcts when a patient has had abnormal electrocardiograms (ECGs) and cardiac enzymes have returned to normal. PYP uptake by acutely infarcted tissue may be related to the influx of calcium through damaged cell membranes, which accompanies myocardial necrosis; that is, the radionuclide may be binding to calcium phosphates or to hydroxyapatite. The PYP in these damaged cells can be viewed as spots of increased radionuclide uptake that appear in 12 hr at the earliest.

PYP uptake usually takes place 24 to 72 hr after MI, and the radionuclide remains detectable for approximately 10 to 14 days after the MI. PYP uptake is proportional to the blood flow to the affected area; with large areas of necrosis, PYP uptake may be maximal around the periphery of a necrotic area, with little uptake being detectable in the poorly perfused center. Most of the PYP is concentrated in regions that have 20% to 40% of the normal blood flow.

Single-photon emission computed tomography (SPECT) can be used to visualize the heart from multiple angles and planes, enabling areas of MI to be viewed with greater accuracy and resolution. This technique removes underlying structures that may confuse interpretation of the results. With the availability of assays of troponins, myocardial infarct imaging has become less important in the diagnosis of acute MI.
INDICATIONS:
• Aid in the diagnosis of (or confirm and locate) acute MI when ECG and enzyme testing do not provide a diagnosis
• Aid in the diagnosis of perioperative MI
• Differentiate between a new and old infarction
• Evaluate possible reinfarction or extension of the infarct
• Obtain baseline information about infarction before cardiac surgery

RESULT:

Normal findings in:
• Normal coronary blood flow and tissue perfusion, with no PYP localization in the myocardium
• No uptake above background activity in the myocardium (note: when PYP uptake is present, it is graded in relation to adjacent rib activity)

Abnormal findings in:
• MI, indicated by increased PYP uptake in the myocardium

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risk of radiation exposure to the fetus
• Patients with hypersensitivity to the radionuclide

Factors that may impair clear imaging:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
• Other nuclear scans done within the previous 24 to 48 hr
• Conditions such as chest wall trauma, cardiac trauma, or recent cardioversion procedure
• Myocarditis
• Pericarditis
• Left ventricular aneurysm
• Metastasis
• Valvular and coronary artery calcifications
• Cardiac neoplasms
• Aneurysms

Other considerations:
• Improper injection of the radionuclide may allow the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses blood flow to the heart.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
• Obtain a history of the patient’s cardiovascular system, symptoms, and results of previously performed
MYOCARDIAL INFARCT SCAN

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to lie very still during the procedure because movement will produce unclear images.

Observe standard precautions, and follow the general guidelines in Appendix A.

Place the patient in a supine position on a flat table with foam wedges to help maintain position and immobilization.

IV radionuclide is administered. The heart is scanned 2 to 4 hr after injection in various positions. In most circumstances, however, SPECT is done so that the heart can be viewed from multiple angles and planes.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

Remove the needle or catheter and apply a pressure dressing over the puncture site.

POST-TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.

No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.

Evaluate the patient’s vital signs. Monitor vital signs and neurological status every 15 min for one hr, then every 2 hr for 4 hr, and then as ordered by HCP. Compare with baseline values. Protocols may vary from facility to facility.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

Instruct the patient to resume normal activity and diet as directed by the HCP.

Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

Laboratory tests and diagnostic and surgical procedures.

Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department by a HCP specializing in this procedure, with support staff, and will take approximately 30–60 minutes. Inform the patient that the technologist will administer an IV injection of the radionuclide and that he or she will need to return 2 to 3 hr later for the scan.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

The patient should fast, restrict fluids, and refrain from smoking for 4 hr prior to the procedure. Instruct the patient to withhold medications for 24 hr before the procedure. Protocols may vary from facility to facility.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

INTRATEST:

Ensure that the patient has complied with dietary and medication restrictions and other pretesting preparations.

Ensure that the patient has removed all external metallic objects prior to the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Access additional resources at davisplus.fadavis.com
Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include angiography abdominal, AST, BNP, blood pool imaging, chest x-ray, CT abdominal, CT thoracic, CK and isoenzymes, culture viral, echocardiography, echocardiography transesophageal, ECG, MRA, MRI chest, myocardial perfusion scan, pericardial fluid analysis, and PET heart.

- Refer to the Cardiovascular System table at the back of the book for related tests by body system.

---

**Myocardial Perfusion Heart Scan**

**SYNONYM/ACRONYM:** Thallium scan, sestamibi scan, stress thallium.

**AREA OF APPLICATION:** Heart, chest/thorax.

**CONTRAST:** IV contrast medium.

**DESCRIPTION:** Cardiac scanning is a nuclear medicine study that reveals clinical information about coronary blood flow, ventricular size, and cardiac function. Thallium-201 chloride rest or stress studies are used to evaluate myocardial blood flow to assist in diagnosing or determining the risk for ischemic cardiac disease, coronary artery disease (CAD), and myocardial
infarction (MI). This procedure is an alternative to angiography or cardiac catheterization in cases in which these procedures may pose a risk to the patient. Thallium-201 is a potassium analogue and is taken up by myocardial cells proportional to blood flow to the cell and cell viability. During stress studies, the radionuclide is injected at peak exercise, after which the patient continues to exercise for several minutes. During exercise, areas of heart muscle supplied by normal arteries increase their blood supply, as well as the supply of thallium-201 delivery to the heart muscle, to a greater extent than regions of the heart muscle supplied by stenosed coronary arteries. This discrepancy in blood flow becomes apparent and quantifiable in subsequent imaging. Comparison of early stress images with images taken after 3 to 4 hr redistribution (delayed images) enables differentiation between normally perfused, healthy myocardium (which is normal at rest but ischemic on stress) and infarcted myocardium.

Technetium-99m agents such as sestamibi (2-methoxyisobutylisonitrile) are delivered similarly to thallium-201 during myocardial perfusion imaging, but they are extracted to a lesser degree on the first pass through the heart and are taken up by the mitochondria. Over a short period, the radionuclide concentrates in the heart to the same degree as thallium-201. The advantage to technetium-99m agents is that immediate imaging is unnecessary because the radionuclide remains fixed to the heart muscle for several hours. The examination requires two separate injections, one for the rest portion and one for the stress portion of the procedure. These injections can take place on the same day or preferably over a 2-day period. Examination quality is improved if the patient is given a light, fatty meal after the radionuclide is injected to facilitate hepatobiliary clearance of the radioactivity.

If stress testing cannot be performed by exercising, dipyridamole (Persantine) or adenosine, a vasodilator, can be administered orally or IV. A coronary vasodilator is administered before the thallium-201, or other radionuclide, and the scanning procedure is then performed. Vasodilators increase blood flow in normal coronary arteries twofold to threefold without exercise, and they reveal perfusion defects when blood flow is compromised by vessel pathology. Vasodilator-mediated myocardial perfusion scanning is reserved for patients who are unable to participate in treadmill, bicycle, or handgrip exercises for stress testing because of lung disease, neurological disorders (e.g., multiple sclerosis, spinal cord injury), morbid obesity, and orthopedic disorders (e.g., arthritis, limb amputation).

Single-photon emission computed tomography can be used to visualize the heart from multiple angles and planes, enabling areas of MI to be viewed with greater accuracy and resolution. This technique removes overlying structures that may confuse interpretation of the results.

**INDICATIONS:**

- Aid in the diagnosis of CAD or risk for CAD
- Determine rest defects and reperfusion with delayed imaging in unstable angina

Access additional resources at davisplus.fadavis.com
• Evaluate the extent of CAD and determine cardiac function
• Assess the function of collateral coronary arteries
• Evaluate bypass graft patency and general cardiac status after surgery
• Evaluate the site of an old MI to determine obstruction to cardiac muscle perfusion
• Evaluate the effectiveness of medication regimen and balloon angioplasty procedure on narrow coronary arteries

RESULT:

Normal findings in:
• Normal wall motion, coronary blood flow, tissue perfusion, and ventricular size and function

Abnormal findings in:
• Abnormal stress and resting images, indicating previous MI
• Abnormal stress images with normal resting images, indicating transient ischemia
• Cardiac hypertrophy, indicated by increased radionuclide uptake in the myocardium
• Enlarged left ventricle
• Heart chamber disorder
• Ventricular septal defects

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients who have taken sildenafil (Viagra) within the previous 48 hr, as this test may require the use of nitrates (nitroglycerin) that can precipitate life-threatening low blood pressure
• Patients with bleeding disorders
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risk of radiation exposure to the fetus
• Patients with hypersensitivity to the radionuclide
• Patients with left ventricular hypertrophy, right and left bundle branch block, hypokalemia, and patients receiving cardiotonic therapy
• Patients with anginal pain at rest or patients with severe atherosclerotic coronary vessels, in whom dipyridamole testing cannot be performed
• Patients with asthma, because chemical stress with vasodilators can cause bronchospasms

Factors that may impair clear imaging:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Medications such as digitalis and quinidine, which can alter cardiac contractility; and nitrates, which can affect cardiac performance
• Single-vessel disease, which can produce false-negative thallium-201 scanning results
• Conditions such as chest wall or cardiac trauma, angina that is difficult to control, significant cardiac arrhythmias, and recent cardioversion procedure
• Suboptimal cardiac stress or patient exhaustion preventing maximum heart rate testing
• Excessive eating or exercising between initial and redistribution imaging 4 hr later, which produces false-positive results
• Improper adjustment of the radiological equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study
• Patients who are very obese, or who may exceed the weight limit for the equipment
• Incorrect positioning of the patient, which may produce poor visualization of the area to be examined
• Metallic objects (e.g., jewelry, body rings) within the examination field,
which may inhibit organ visualization and cause unclear images.

**Other considerations:**
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- Inaccurate timing for imaging after radionuclide injection can affect the results.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to reveal their level of exposure to radiation.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses blood flow to the heart.
- Obtain a history of the patient’s complaints and symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular system, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain and explain that some pain may be experienced during the test, or there may be moments of discomfort. Inform the patient that the procedure is performed in a special department, usually in a radiology or vascular suite, by a HCP specializing in this procedure and support staff, and takes approximately 30 to 60 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, dye, or sedatives. Usually normal saline is infused.
- Instruct the patient to wear walking shoes (if treadmill exercise testing is to be performed), and emphasize the importance of reporting fatigue, pain, or shortness of breathe.
- Instruct the patient to remove dentures, jewelry, and other metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to fast for 4 hr, refrain from smoking for 4 to 6 hr, and withhold medications for 24 hr before the test. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.
- This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.

**INTRATEST:**
- Ensure that the patient has complied with dietary, tobacco, and medication restrictions and other pretesting preparations for 4 to 6 hr prior to the procedure.
POST-TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.

No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.

Evaluate the patient’s vital signs. Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by HCP. Compare with baseline values. Protocols may vary from facility to facility.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

Instruct the patient to resume normal diet and activity, as directed by the HCP.

Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

Instruct the patient in the care and assessment of the injection site. Observe for bleeding, hematoma formation, and inflammation.

If the patient must return for additional imaging, advise the patient to rest in the interim and restrict diet to liquids before redistribution studies.

If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.

Instruct the patient to flush the toilet immediately after each voiding following the procedure, and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.

Ensure that the patient has removed external metallic objects from the area to be examined prior to the procedure.

Have emergency equipment readily available.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.

Instruct the patient to void prior to the procedure and change into the gown, robe, and foot coverings provided.

Record baseline vital signs and assess neurological status. Protocols may vary from facility to facility.

Instruct the patient to cooperate fully and to follow directions.

Observe standard precautions, and follow the general guidelines in Appendix A.

Establish IV fluid line for the injection of emergency drugs and of sedatives.

Place electrocardiographic (ECG) electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias. Monitor the patient’s blood pressure throughout the procedure by using an automated blood pressure machine.

Assist the patient onto the treadmill or bicycle ergometer and ask the patient to exercise to a calculated 80% to 85% of the maximum heart rate, as determined by the protocol selected.

Wear gloves during the radionuclide injection and while handling the patient’s urine.

Thallium-201 is injected 60 to 90 sec before exercise is terminated, and imaging is done immediately in the supine position and repeated in 4 hr.

Patients who cannot exercise are given dipyridamole 4 min before thallium-201 is injected.

Inform the patient that movement during the resting procedure affects the results and makes interpretation difficult.

The results are recorded on film or in a computerized system for recall and postprocedure interpretation by the appropriate HCP.
Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, atrial natriuretic peptide, BNP, calcium, cholesterol (total, HDL, LDL), CT cardiac scoring, CRP, CK and isoenzymes, echocardiography, echocardiography transesophageal, ECG, exercise stress test, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isos, lipoprotein electrophoresis, magnesium, MRI chest, MI infarct scan, myoglobin, PET heart, potassium, triglycerides, and troponin.
- Refer to the Cardiovascular System table at the back of the book for related tests by body system.

**Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.**

**Nutritional considerations:** A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.

- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

**Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.**

**Nutritional considerations:** A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.

**DESCRIPTION:** Myoglobin is an oxygen-binding muscle protein normally found in skeletal and cardiac muscle. It is released into the bloodstream after muscle damage from ischemia, trauma, or inflammation. Although myoglobin testing is more sensitive than creatinine kinase and isoenzymes, it does not indicate the specific site involved.
**INDICATIONS:**
- Assist in predicting a flareup of polymyositis
- Estimate damage from skeletal muscle injury or myocardial infarction (MI)

**RESULT:**

**Increased in:**
- Conditions that cause muscle damage; damaged muscle cells release myoglobin into circulation.
- Cardiac surgery
- Cocaine use (*Rhabdomyolysis is a complication of cocaine use or overdose*)
- Exercise
- Malignant hyperthermia
- MI
- Progressive muscular dystrophy
- Renal failure
- Rhabdomyolysis
- Shock
- Thrombolytic therapy

**Decreased in:**
- Myasthenia gravis
- Presence of antibodies to myoglobin, as seen in patients with polymyositis
- Rheumatoid arthritis

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:** N/A

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of skeletal or myocardial muscle damage.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular and musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture. Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, ANP, blood gases, BNP, calcium, cholesterol (total, HDL, and LDL), CRP, CK and isoenzymes, CT cardiac scoring, echocardiography, echocardiography transesophageal, ECG, exercise stress test, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI chest, MI infarct scan, myoglobin, pericardial fluid analysis, PET heart, potassium, triglycerides, and troponin.
- Refer to the Cardiovascular and Musculoskeletal System tables at the back of the book for related tests by body system.
Nerve Fiber Analysis

SYNONYM/ACRONYM: NFA.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION: There are over 1 million ganglion nerve cells in the retina of each eye. Each nerve cell has a long fiber that travels through the nerve fiber layer of the retina and exits the eye through the optic nerve. The optic nerve is made up of all the ganglion nerve fibers and connects the eye to the brain for vision to occur. As the ganglion cells die, the nerve fiber layer becomes thinner and an empty space in the optic nerve, called the cup, becomes larger. The thinning of the nerve fiber layer and the enlargement of the nerve fiber cup are measurements used to gauge the extent of damage to the retina. Significant damage to the nerve fiber layer occurs before loss of vision is noticed by the patient. Damage can be caused by glaucoma or by aging or occlusion of the vessels in the retina. Ganglion cell loss due to glaucoma begins in the periphery of the retina, thereby first affecting peripheral vision. This change in vision can also be detected by visual field testing. There are several different techniques for measuring nerve fiber layer thickness. One of the most common employs the use of a laser that emits polarizing light waves. The laser’s computer measures the change in direction of alignment of the light beam after it passes through the nerve fiber layer tissue. The amount of change in polarization correlates to the thickness of the retinal nerve fiber layer.

INDICATIONS:
• Assist in the diagnosis of eye diseases
• Determine retinal nerve fiber layer thickness
• Monitor the effects of various therapies or the progression of conditions resulting in loss of vision

RESULT:
Normal findings in:
• Normal nerve fiber layer thickness

Abnormal findings in:
• Glaucoma or suspicion of glaucoma
• Ocular hypertension

CRITICAL VALUES: N/A

INTERFERING FACTORS:
Factors that may impair the results of the examination:
• Inability of the patient to fixate on focal point
• Corneal disorder that prevents proper alignment of the retinal nerve fibers
• Dense cataract that prevents visualization of a clear nerve fiber image
• Inability of the patient to cooperate or remain still during the test because of age, significant pain, or mental status

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➧ Inform the patient that the procedure measures the thickness of the retinal nerve fiber layer.
Obtain a history of the patient’s complaints, including a list of known allergens.

Obtain a history of known or suspected visual impairment, changes in visual acuity, and use of glasses or contact lenses.

Obtain a history of narrow-angle glaucoma. Obtain a history of known or suspected vision loss, including type and cause; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.

Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.

Review the procedure with the patient. Explain that the patient will be requested to fixate the eyes during the procedure. Address concerns about pain and explain that no pain will be experienced during the test, but there may be moments of discomfort. Explain to the patient that some discomfort may be experienced after the test when the numbness wears off from anesthetic drops administered prior to the test. Inform the patient that a health care provider (HCP) performs the test and that to evaluate both eyes, the test can take 10 to 15 min.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRA.TEST:**

Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.

Seat the patient comfortably. Instruct the patient to look straight ahead, keeping the eyes open and unblinking.

Instill topical anesthetic in each eye, as ordered, and allow time for it to work. Topical anesthetic drops are placed in the eye with the patient looking up and the solution directed at the six o’clock position of the sclera (white of the eye) near the limbus (grey, semitransparent area of the eyeball where the cornea and sclera meet). Neither the dropper nor the bottle should touch the eyelashes.

The equipment used to perform the test determines whether dilation of the pupils is required (OCT) or avoided (GDX).

Request that the patient look straight ahead at a fixation light with the chin in the chin rest and forehead against the support bar. The patient should be reminded not to move the eyes or blink the eyelids as the measurement is taken. The person performing the test can store baseline data or retrieve previous images from the equipment. The equipment can create the mean image from current and previous data, and its computer can make a comparison against previous images.

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss or anticipated loss of driving privileges. Discuss the implications of abnormal test results on the patient’s lifestyle.

Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information, if desired, for the Glaucoma Research Foundation (www.glaucoma.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient in the use of any ordered medications, usually eye drops. Explain the importance of adhering to the therapy regimen, especially since glaucoma does not present symptoms. Instruct the patient in both the ocular side effects and systemic reactions associated with the prescribed medication. Encourage him or
her to review corresponding literature provided by a pharmacist. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include fundus photography, gonioscopy, pachymetry, slit-lamp biomicroscopy, and visual field testing.
- Refer to the Ocular System table at the back of the book for related tests by body system.
Osmolality, Blood and Urine

SYNONYM/ACRONYM: Osmo.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube; urine (5 mL) from an unpreserved random specimen collected in a clean plastic collection container.

REFERENCE VALUE: (Method: Freezing point depression)

<table>

DESCRIPTION: Osmolality refers to the number of particles in solution; it is independent of particle size, shape, and charge. Measurement of osmotic concentration in serum provides clinically useful information about water and dissolved-particle transport across fluid compartment membranes. Osmolality is used to assist in the diagnosis of metabolic, renal, and endocrine disorders. The simultaneous determination of serum and urine osmolality provides the opportunity to compare values between the two fluids. A normal urine-to-serum ratio is approximately 0.2 to 4.7 for random samples and greater than 3.0 for first-morning samples (dehydration normally occurs overnight). The major dissolved particles that contribute to osmolality are sodium, chloride, bicarbonate, urea, and glucose. Some of these substances are used in the following calculated estimate:

\[
\text{Serum osmolality} = (2 \times \text{Na}^+) + \frac{(\text{glucose/18}) + (\text{BUN/2.8})}{1}
\]

Measured osmolality is higher than the estimated value. The osmolar gap is the difference between the measured and calculated values and is normally 5 to 10 mOsm/kg. If the difference is greater than 15 mOsm/kg, consider ethylene glycol, isopropanol, methanol, or ethanol toxicity. These substances behave like antifreeze, lowering the freezing point in the blood, and provide misleadingly high results.

INDICATIONS:

**Serum:**
- Assist in the evaluation of antidiuretic hormone (ADH) function
- Assist in rapid screening for toxic substances, such as ethylene glycol, ethanol, isopropanol, and methanol
- Evaluate electrolyte and acid-base balance
- Evaluate state of hydration

**Urine:**
- Evaluate concentrating ability of the kidneys
- Evaluate diabetes insipidus
- Evaluate neonatal patients with protein or glucose in the urine
- Perform work-up for renal disease

RESULT:

**Increased in:**
- Serum:
  - Azotemia (Nitrogen containing waste products that contribute to osmolality accumulate in the blood)
Dehydration (Hemoconcentration)
Diabetes insipidus (Excessive loss of water through urination results in hemoconcentration)
Diabetic ketoacidosis (Excessive loss of water through urination results in hemoconcentration)
Hypercalcemia (Electrolyte imbalance that results in water loss and hemoconcentration)
Hypokalemia (Related to insufficient intake of water or excessive loss of water; sodium is a major cation in the determination of osmolality)

Urine:
Amyloidosis
Azotemia (Decrease in renal blood flow; decrease in water excreted by the kidneys results in a more concentrated urine)
Congestive heart failure (Decrease in renal blood flow related to diminished cardiac output; decrease in water excreted by the kidneys results in a more concentrated urine)
Dehydration (Decrease in water excreted by the kidneys results in a more concentrated urine)
Hyponatremia
Syndrome of inappropriate antidiuretic hormone production (SIADH) (Related to overproduction of ADH; decrease in water excreted by the kidneys results in a more concentrated urine)

Decreased in:
• Serum:
  Adrenocortical insufficiency
  Hyponatremia
  SIADH
  Water intoxication
• Urine:
  Diabetes insipidus
  Hypermastria
  Hypokalemia
  Primary polydipsia

CRITICAL VALUES: ☑

Serum:
Less than 265 mOsm/kg
Greater than 320 mOsm/kg

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms.

Serious clinical conditions may be associated with elevated or decreased serum osmolality. The following conditions are associated with elevated serum osmolality:

Respiratory arrest: 360 mOsm/kg
Stupor of hyperglycemia: 385 mOsm/kg
Grand mal seizures: 420 mOsm/kg
Death: greater than 420 mOsm/kg

Symptoms of critically high levels include poor skin turgor, listlessness, acidosis (decreased pH), shock, seizures, coma, and cardiopulmonary arrest. Intervention may include close monitoring of electrolytes, administering intravenous fluids with the appropriate composition to shift water either into or out of the intravascular space as needed, monitoring cardiac signs, continuing neurological checks, and taking seizure precautions.

INTERFERING FACTORS:
• Drugs that may increase serum osmolality include citrates (as an anticoagulant), corticosteroids, ethylene glycol, glycerin, inulin, ioxithalamic acid, mannitol, and methoxyflurane.
• Drugs that may decrease serum osmolality include bendroflu- methiazide, carbamazepine, chlorpromazine, chlorthalidone, cyclophosphamid, cyclothiazide, hydrochlorothiazide, lorcanide, methyclothiazide, and polythiazide.
• Drugs that may increase urine osmolality include anesthetic agents, chlorpropamide, cyclophosphamide, furosemide, mannitol, metolazone, octreotide, phosphidzin, and vincristine.
• Drugs that may decrease urine osmolality include captopril, demectocycline, glyburide, lithium, methoxyflurane, octreotide, tola- mide, and verapamil.
NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate electrolyte and water balance.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that blood specimen collection takes approximately 5 to 10 min; random urine collection takes approximately 5 min and depends on the cooperation of the patient. Urine specimen collection may also be timed. Address concerns about pain and explain that there may be some discomfort during the venipuncture; there will be no discomfort during urine collection.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
- Direct the patient to breathe normally and to avoid unnecessary movement during the venipuncture.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes or collection containers with the corresponding patient demographics, date, and time of collection.

Blood:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Urine:
- Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device.
- Either a random specimen or a timed collection may be requested. For timed specimens, a 12- or 24-hr time frame for urine collection may be ordered. Inform the patient that all urine must be saved during that 12- or 24-hr period.
- Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

Clean-Catch Specimen:
- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling Catheter:
- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Blood or Urine:
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Access additional resources at davisplus.fadavis.com
SYNONYM/ACRONYM: Red blood cell osmotic fragility, OF.

SPECIMEN: Whole blood (1 mL) collected in a green-top (heparin) tube and two peripheral blood smears.

REFERENCE VALUE: (Method: Spectrophotometry) Hemolysis (unincubated) begins at 0.5 w/v sodium chloride (NaCl) solution and is complete at 0.3 w/v NaCl solution. Results are compared to a normal curve.

RESULT:

*Increased in:*

- Conditions that produce red blood cells (RBCs) with a small surface to volume ratio or RBCs that are rounder than normal will have increased osmotic fragility.
- Acquired immune hemolytic anemias (*Abnormal RBCs in size and shape; spherocytes*)
- Hemolytic disease of the newborn (*Abnormal RBCs in size and shape; spherocytes*)
- Hereditary spherocytosis (*Abnormal RBCs in size and shape; spherocytes*)
- Malaria (Related to affect of parasite on RBC membrane integrity)
- Pyruvate kinase deficiency (*Abnormal RBCs in size and shape; spherocytes*)

*Decreased in:*

- Conditions that produce RBCs with a large surface to volume ratio (RBCs that are more discocyte than normal) will have decreased osmotic fragility.
- Sickle cell anemia (*Abnormal RBCs in shape; sickles*)
- Thalassemia (*Abnormal RBCs in shape; spherocytes*)

*Nutritional considerations:* Decreased osmolality may be associated with overhydration. Observe the patient for signs and symptoms of fluid-volume excess related to excess electrolyte intake, fluid-volume deficit related to active body fluid loss, or risk of injury related to an alteration in body chemistry. (For electrolyte-specific dietary references, see monographs titled “Chloride,” “Potassium,” and “Sodium.”)

Increased osmolality may be associated with dehydration. Evaluate the patient for signs and symptoms of dehydration. Dehydration is a significant and common finding in geriatric and other patients in whom renal function has deteriorated.

*Recognize anxiety related to test results.* Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the National Kidney Foundation (www.kidney.org).

*Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.*

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

*Related tests include ACTH, anion gap, ammonia, ADH, ANP, BNP, BUN, calcium, carbon dioxide, chloride, cortisol, creatinine, echocardiography, echocardiography transesophageal, ethanol, glucose, complete blood count, hematocrit, complete blood count, hemoglobin, ketones, lung perfusion scan, magnesium, phosphorus, potassium, sodium, and UA.*

*Related monographs:*

- Refer to the Endocrine and Genitourinary System tables at the back of the book for related tests by body system.
Decreased in:
Conditions that produce RBCs with a large surface to volume ratio or RBCs that are flatter than normal will have decreased osmotic fragility.
• Asplenia (Abnormal cells are not removed from circulation due to absence of spleen; target cells)
• Hemoglobinopathies (Abnormal RBCs in size and shape; target cells)
• Iron-deficiency anemia (Abnormal RBCs in size and shape; target cells)
• Liver disease (Abnormal RBCs in size and shape; target cells)
• Thalassemias (Abnormal RBCs in size and shape; target cells)

CRITICAL VALUES: N/A

Find and print out the full monograph at DavisPlus (davisplus.fadavis.com, keyword Van Leeuwen).

## Osteocalcin

**SYNONYM/ACRONYM:** Bone GLA protein, BGP.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Radioimmunoassay)

**DESCRIPTION:** Osteocalcin is an important bone cell matrix protein and a sensitive marker in bone metabolism. It is produced by osteoblasts during the matrix mineralization phase of bone formation and is the most abundant noncollagenous bone cell protein. Synthesis of osteocalcin is dependent on vitamin K. Osteocalcin levels parallel alkaline phosphatase levels. Osteocalcin levels are affected by a number of factors, including the hormone estrogen. Assessment of osteocalcin levels permits indirect measurement of osteoblast activity and bone formation. Because it is released into the bloodstream during bone resorption, there is some question as to whether osteocalcin might also be considered a marker for bone matrix degradation and turnover.

Access additional resources at davisplus.fadavis.com
INDICATIONS:
• Assist in the diagnosis of bone cancer
• Evaluate bone disease
• Evaluate bone metabolism
• Monitor effectiveness of estrogen replacement therapy

RESULT:
*Increased in:*
• Adolescents undergoing a growth spurt (*Levels in the blood increase as the rate of bone formation increases*)
• Chronic renal failure (*Related to accumulation in circulation due to decreased renal excretion*)
• Hyperthyroidism (primary and secondary) (*Related to increased bone turnover*)
• Metastatic skeletal disease (*Levels in the blood increase as bone destruction releases it into circulation*)
• Paget’s disease (*Levels in the blood increase as bone destruction releases it into circulation*)
• Renal osteodystrophy (*Related to bone degeneration secondary to hyperparathyroidism of chronic renal failure*)
• Some patients with osteoporosis (*Levels in the blood increase as bone destruction releases it into circulation*)

*Decreased in:*
• Growth hormone deficiency (*Bone mineralization is stimulated by growth hormone*)
• Pregnancy (*Increased demand by developing fetus results in an increase in maternal bone resorption*)
• Primary biliary cirrhosis (*Related to increased bone loss*)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may increase osteocalcin levels include anticonvulsants, calcitriol, and estrogens.
• Drugs that may decrease osteocalcin levels include glucocorticoids.
• Recent radioactive scans or radiation within 1 week before the serum osteocalcin test can interfere with test results when radioimmunoassay is the test method.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to evaluate bone disease.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Note any recent procedures that can interfere with test results.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient.
• Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
• Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
• If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
• Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
• Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient
demographics, date, and time of collection. Perform a venipuncture.

- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- **Nutritional considerations:** Increased osteocalcin levels may be associated with skeletal disease. Nutritional therapy is indicated for individuals identified as being at high risk for developing osteoporosis. Educate the patient regarding the National Osteoporosis Foundation’s guidelines, which include a regular regimen of weight-bearing exercises, limited alcohol intake, avoidance of tobacco products, and adequate dietary intake of vitamin D (400 to 800 IU/day) and calcium (120 mg/day). Dietary calcium can be obtained from animal or plant sources. Milk and milk products, sardines, clams, oysters, salmon, rhubarb, spinach, beet greens, broccoli, kale, tofu, legumes, and fortified orange juice are high in calcium. Milk and milk products also contain vitamin D and lactose, which assist calcium absorption. Cooked vegetables yield more absorbable calcium than raw vegetables. Patients should be informed of the substances that can inhibit calcium absorption by irreversibly binding to some of the calcium, making it unavailable for absorption, such as oxalates, which naturally occur in some vegetables; phytic acid, found in some cereals; and insoluble dietary fiber (in excessive amounts). Excessive protein intake can also negatively affect calcium absorption, especially if it is combined with foods high in phosphorus. Vitamin D is synthesized by the skin and is also available in fortified dairy foods and cod liver oil.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ALP, biopsy bone, BMD, bone scan, calcium, collagen cross-linked N-telopeptide, MRI musculoskeletal, PTH, phosphorus, radiography bone, and vitamin D.
- Refer to the Musculoskeletal System table for related tests by body system.

---

**Otoscopy**

**SYNONYM/ACRONYM:** N/A.

**AREA OF APPLICATION:** Ears.

**CONTRAST:** N/A.

**DESCRIPTION:** This noninvasive procedure is used to inspect the external ear, auditory canal, and tympanic membrane. Otoscopy is an essential part of any general physical examination, but is also done before any other audiological studies when symptoms of ear pain or hearing loss are present.
INDICATIONS:

• Detect causes of deafness, obstruction, stenosis, or swelling of the pinna or canal causing a narrowing or closure that prevents sound from entering
• Detect ear abnormalities during routine physical examination
• Diagnose cause of ear pain
• Remove impacted cerumen (with a dull ring curette) or foreign bodies (with a forceps) that are obstructing the entrance of sound waves into the ear
• Evaluate acute or chronic otitis media and effectiveness of therapy in controlling infections

RESULT:

Normal findings in:

• Normal structure and appearance of the external ear, auditory canal, and tympanic membrane.
  
  Pinna: funnel-shaped cartilaginous structure; no evidence of infection, pain, dermatitis with swelling, redness, or itching

  External auditory canal: S-shaped canal lined with fine hairs, sebaceous and ceruminous glands; no evidence of redness, lesions, edema, scaliness, pain, accumulation of cerumen, drainage, or presence of foreign bodies

  Tympanic membrane: shallow, circular cone that is shiny and pearl gray in color, semitransparent whitish cord crossing from front to back just under the upper edge, cone of light on the right side at the 4 o'clock position; no evidence of bulging, retraction, lusterless membrane, or obliteration of the cone of light

Abnormal findings in:

• Cerumen accumulation
• Ear trauma
• Foreign bodies
• Otitis externa
• Otitis media
• Tympanic membrane perforation or rupture

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair the results of the examination:

• Obstruction of the auditory canal with cerumen, dried drainage, or foreign bodies that prevent introduction of the otoscope

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➧ Inform the patient that the procedure is performed to investigate suspected ear disorders.
➧ Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
➧ Obtain a history of the patient’s known or suspected hearing loss, including type and cause; ear conditions with treatment regimens; ear surgery; and other tests and procedures to assess and diagnose auditory deficit. Obtain a history of the patient’s complaints of pain, itching, drainage, deafness, or presence of tympanotomy tube.
➧ Obtain a history of symptoms and results of previously performed laboratory tests, diagnostic and surgical procedures.
➧ Obtain a list of the patient’s current medications, especially antibiotic regimens, as well as herbs, nutritional supplements, and nutraceuticals.
➧ Review the procedure with the patient. Inform the caregiver that he or she may need to restrain a child in order to prevent damage to the ear if the child cannot remain still. Address concerns about pain and explain that no discomfort will be experienced during the test. Inform the patient that a health care provider (HCP) performs the test, and that to evaluate both ears, the test can take 5 to 10 min.
➧ Sensitivity to social and cultural issues, as well as Concern for modesty, is important
in providing psychological support before, during, and after the procedure.

- There are no food, fluid, or medication restrictions, unless by medical direction.
- Ensure that the external auditory canal is clear of impacted cerumen.

**INTRATEST:**

- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- Administer ear drops or irrigation to prepare for cerumen removal, if ordered.
- Place adult patient in a sitting position; place a child in a supine position on the caregiver’s lap. Request that the patient remain very still during the examination; a child can be restrained by the caregiver if needed.
- Assemble the otoscope with the correct-size speculum to fit the size of the patient’s ear and check the light source. For the adult, tilt the head slightly away and, with the nondominant hand, pull the pinna upward and backward. For a child, hold the head steady or have the caregiver hold the child’s head steady, depending on the age, and pull the pinna downward. Gently and slowly insert the speculum into the ear canal downward and forward with the handle of the otoscope held downward. For the child, hold the handle upward while placing the edge of the hand holding the otoscope on the head to steady it during insertion. If the speculum resists insertion, withdraw and attach a smaller one.
- Place an eye to the lens of the otoscope, turn on the light source, and advance the speculum into the ear canal until the tympanic membrane is visible. Examine the posterior and anterior membrane, cone of light, outer rim (annulus), umbo, handle of the malleus, folds, and pars tensa.
- Culture any effusion with a sterile swab and culture tube (see “Culture, Bacterial, Ear,” monograph); or a HCP will perform needle aspiration from the middle ear through the tympanic membrane during the examination. Other procedures such as cerumen and foreign body removal can also be performed.
- Pneumatic otoscopy can be done to determine tympanic membrane flexibility. This test permits the introduction of air into the canal that reveals a reduction in movement of the membrane in otitis media and absence of movement in chronic otitis media.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Administer ear drops of a soothing oil, as ordered, if the canal is irritated by removal of cerumen or foreign bodies.
- Recognize anxiety related to test results, and be supportive of impaired activity related to hearing loss. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include audiometry hearing loss, culture bacterial (ear), and gram stain.
- Refer to the Auditory System table at the back of the book for related tests by body system.
SYNONYM/ACRONYM: O & P.

SPECIMEN: Stool collected in a clean plastic, tightly capped container.

REFERENCE VALUE: (Method: Macroscopic and microscopic examination) No presence of parasites, ova, or larvae.

DESCRIPTION: This test evaluates stool for the presence of intestinal parasites and their eggs. Some parasites are nonpathogenic; others, such as protozoa and worms, can cause serious illness.

INDICATIONS: Assist in the diagnosis of parasitic infestation.

RESULT: Positive findings in:
- Amebiasis—Entamoeba histolytica infection
- Ascariasis—Ascaris lumbricoides infection
- Blastocystis—Blastocystis hominis infection
- Cryptosporidiosis—Cryptosporidium parvum infection
- Enterobiasis—Enterobius vermicularis (pinworm) infection
- Giardiasis—Giardia lamblia infection
- Hookworm disease—Ancylostoma duodenale, Necator americanus infection
- Isospora—Isospora belli infection
- Schistosomiasis—Schistosoma haematobium, S. japonicum, S. mansoni infection
- Strongyloidiasis—Strongyloides stercoralis infection
- Tapeworm disease—Diphyllobothrium, Hymenolepiasis, Taenia saginata, T. solium infection
- Trematode disease—Clonorchis sinensis, Fasciola hepatica, Fasciolopsis buski infection
- Trichuriasis—Trichuris trichiura infection

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Failure to test a fresh specimen may yield a false-negative result.
- Antimicrobial or antiamebic therapy within 10 days of test may yield a false-negative result.
- Failure to wait 1 wk after a gastrointestinal study using barium or after laxative use can affect test results.
- Medications such as antacids, antibiotics, antidiarrheal compounds, bismuth, castor oil, iron, magnesium, or psyllium fiber (Metamucil) may interfere with analysis.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of parasitic infection.
- Obtain a history of the patient's complaints, including a list of known
allergens. Document any travel to foreign countries.

- Obtain a history of the patient’s gastrointestinal and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent therapies that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Instruct the patient on handwashing procedures, and inform the patient that the infection may be contagious. Warn the patient not to contaminate the specimen with urine, toilet paper, or toilet water. Address concerns about pain and explain to the patient that there should be no discomfort during the procedure.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to avoid medications that interfere with test results.
- There are no food or fluid restrictions, unless by medical direction.

**INTRATEST:**

- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.
- Collect a stool specimen directly into the container. If the patient is bedridden, use a clean bedpan and transfer the specimen into the container using a tongue depressor.
- Specimens to be examined for the presence of pinworms are collected by the “Scotch tape” method in the morning before bathing or defecation. A small paddle with a piece of cellophane tape (sticky side facing out) is pressed against the perianal area. The tape is placed in a collection container and submitted to determine if ova are present. Sometimes adult worms are observed protruding from the rectum. Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Educate the patient with positive findings on the transmission of the parasite, as indicated. Warn the patient that one negative result does not rule out parasitic infestation and that additional specimens may be required. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include biopsy intestinal, biopsy liver, biopsy muscle, culture stool, fecal analysis, and IgE.
- Refer to the Gastrointestinal and Immune System tables at the back of the book for related tests by body system.
**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Urine (25 mL) from a timed specimen collected in a clean plastic collection container with hydrogen chloride (HCl) as a preservative.

**REFERENCE VALUE:** (Method: Spectrophotometry)

**DESCRIPTION:** Oxalate is derived from the metabolism of oxalic acid, glycine, and ascorbic acid. Some individuals with malabsorption disorders absorb and excrete abnormally high amounts of oxalate, resulting in *hyperoxaluria*. Hyperoxaluria may be seen in patients who consume large amounts of animal protein, certain fruits and vegetables, or megadoses of vitamin C (ascorbic acid). Hyperoxaluria is also associated with ethylene glycol poisoning (oxalic acid is used in cleaning and bleaching agents). Patients who absorb and excrete large amounts of oxalate may form calcium oxalate kidney stones. Simultaneous measurement of serum and urine calcium is often requested.

**RESULT:**

*Increased in:*

*Conditions that result in malabsorption for any reason can lead to increased levels. Chronic diarrhea results in excessive loss of calcium to bind oxalate. Increased oxalate is absorbed by the intestine and excreted by the kidneys.*

- Bacterial overgrowth
- Biliary tract disease
- Bowel disease
- Celiac disease
- Cirrhosis
- Crohn’s disease
- Diabetes
- Ethylene glycol poisoning
  *(Ethylene glycol is metabolized to oxalate and excreted by the kidneys; crystals are present in urine)*
- Ileal resection
- Jejunal shunt
- Pancreatic disease
- Primary hereditary hyperoxaluria
  *(rare)*
- Pyridoxine (vitamin B6) deficiency
  *(Pyridoxine is a cofactor in an enzyme reaction that converts glyoxylic acid to glycine; deficiencies result in an increase in oxalate)*
- Sarcoidosis

**INDICATIONS:**

- Assist in the evaluation of patients with ethylene glycol poisoning
- Assist in the evaluation of patients with a history of kidney stones
- Assist in the evaluation of patients with malabsorption syndromes or patients who have had jejunoileal bypass surgery
Oxalate, Urine

Decreased in:
• Hypercalciuria *(Related to formation of calcium oxalate crystals)*
• Renal failure *(Related to oxalate kidney stone disease)*

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
• Drugs and vitamins that may increase oxalate levels include methoxyflurane, ascorbic acid, and calcium.
• Drugs that may decrease oxalate levels include nifedipine and pyridoxine.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS**

**AND PROCEDURE**

**PRETEST:**

➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

➧ Inform the patient that the test is used to identify patients at risk for renal calculus formation, specifically calcium oxalate calculi. Hyperoxaluria is also commonly observed in patients with malabsorption conditions.

➧ Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

➧ Obtain a history of the patient’s gastrointestinal (GI) and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

➧ Obtain a list of the patient’s current medications, including herbs, nutritional supplements and nutraceuticals.

➧ Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

➧ Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.

➧ Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

➧ There are no fluid or medication restrictions, unless by medical direction.

➧ Calcium supplements, gelatin, rhubarb, spinach, strawberries, tomatoes, and vitamin C should be restricted for at least 24 hr before the test. High-protein meals should also be avoided 24 hr before specimen collection. Protocols may vary from facility to facility.

**INTRATEST:**

➧ Ensure that the patient has complied with dietary restrictions; assure that restricted foods have been avoided for at least 24 hr prior to the procedure.

➧ If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

➧ Instruct the patient to cooperate fully and to follow directions.

➧ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection.

**Random Specimen (Collect in Early Morning):**

**Clean-Catch Specimen:**

➧ Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.

Access additional resources at davisplus.fadavis.com
Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

**Indwelling Catheter:**
Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

**Timed Specimen:**
Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.

Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.

If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.

At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.

Include on the collection container’s label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.

**General:**
Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Instruct the patient to resume usual diet, as directed by the HCP.

**Nutritional considerations:** Consideration may be given to lessening dietary intake of oxalate if urine levels are increased. Encourage patients with abnormal results to seek advice regarding dietary modifications from a trained nutritionist. Magnesium supplementation may be recommended for patients with GI disease to prevent the development of calcium oxalate kidney stones.

Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.

Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
Related tests include calcium, calculus kidney stone panel, UA, urine uric acid, and vitamin C.

Refer to the Gastrointestinal and Genitourinary System tables at the back of the book for related tests by body system.
Pachymetry

SYNONYM/ACRONYM: N/A.

AREA OF APPLICATION: Eyes.

DESCRIPTION: Pachymetry is the measurement of the thickness of the cornea using an ultrasound device called a pachymeter. Refractive surgery procedures such as LASIK remove tissue from the cornea. Pachymetry is used to ensure that there will be enough central corneal tissue remaining after surgery to prevent ectasia, or abnormal bowing, of thin corneas. Also, studies point to a correlation between increased risk of glaucoma and decreased corneal thickness. This correlation has influenced some health care providers (HCPs) to include pachymetry as a part of a regular eye health examination for patients who have a family history of glaucoma or who are part of a high-risk population. African Americans have a higher incidence of glaucoma than any other ethnic group.

INDICATIONS:
• Assist in the diagnosis of glaucoma (note: the intraocular pressure in glaucoma patients with a thin cornea, 530 or less, may be higher than in patients whose corneal thickness is within normal limits)
• Determine corneal thickness in potential refractive surgery candidates
• Monitor the effects of various therapies using eye drops, laser, or filtering surgery

RESULT:
Normal findings in:
• 535 to 555 micron

Abnormal findings in:
• Bullous keratopathy
• Corneal rejection after penetrating keratoplasty
• Fuchs endothelial dystrophy
• Glaucoma

CRITICAL VALUES: N/A

INTERFERING FACTORS:
Factors that may impair the results of the examination:
• Inability of the patient to cooperate or remain still during the test because of age, significant pain, or mental status
• Improper technique during application of the probe tip to the cornea

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure measures corneal thickness.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of narrow-angle glaucoma. Obtain a history of known or suspected visual impairment, changes in visual acuity, and use of glasses or contact lenses.
Obtain a history of the patient’s known or suspected vision loss, including type and cause; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.

Obtain a history of symptoms and results of previously performed laboratory tests, diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Instruct the patient to remove contact lenses or glasses, as appropriate.

Instruct the patient regarding the importance of keeping the eyes open for the test.

Review the procedure with the patient. Explain that the patient will be requested to fixate the eyes during the procedure. Address concerns about pain and explain that no pain will be experienced during the test, but there may be moments of discomfort. Explain to the patient that some discomfort may be experienced after the test when the numbness wears off from anesthetic drops administered prior to the test, or discomfort may occur if too much pressure is used during the test. Inform the patient that a HCP performs the test, and that to evaluate both eyes, the test can take 3 to 5 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.

Seat the patient comfortably. Instruct the patient to look straight ahead, keeping the eyes open and unblinking.

Instill topical anesthetic in each eye, as ordered, and allow time for it to work. Topical anesthetic drops are placed in the eye with the patient looking up and the solution directed at the six o’clock position of the sclera (white of the eye) near the limbus (grey, semitransparent area of the eyeball where the cornea and sclera meet). Neither the dropper nor the bottle should touch the eyelashes.

Request that the patient look straight ahead while the probe of the pachymeter is applied directly on the cornea of the eye. Take an average of three readings for each eye. Individual readings should be within 10 microns. Results on both eyes should be similar.

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Recognize anxiety related to test results. Encourage the family to recognize and be supportive of impaired activity related to vision loss, anticipated loss of driving privileges, or the possibility of requiring corrective lenses (self-image). Discuss the implications of test results on the patient’s lifestyle. Reassure the patient regarding concerns related to their impending cataract surgery. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information, if desired, for the Glaucoma Research Foundation (www.glaucoma.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include fundus photography, gonioscopy, intraocular pressure, and visual field testing.

Refer to the Ocular System table at the back of the book for related tests by body system.
**Papanicolaou Smear**

**SYNONYM/ACRONYM:** Pap smear, cervical smear.

**SPECIMEN:** Cervical and endocervical cells.

**REFERENCE VALUE:** (Method: Microscopic examination of fixed and stained smear) Reporting of Pap smear findings may follow one of several formats and may vary from laboratory to laboratory. Simplified content of the two most common formats for interpretation are listed in the table.

*(table continues on page 916)*
**DESCRIPTION:** The Papanicolaou (Pap) smear is primarily used for the early detection of cervical cancer. The interpretation of Pap smears is as heavily dependent on the collection and fixation technique as it is on the completeness and accuracy of the clinical information provided with the specimen. The patient’s age, date of last menstrual period, parity, surgical status, postmenopausal status, use of hormone therapy (including use of oral contraceptives), history of radiation or chemotherapy, history of abnormal vaginal bleeding, and history of previous Pap smears are essential for proper interpretation. Human papillomavirus (HPV) is the most common sexually transmitted virus and primary causal factor in the development of cervical cancer. It is for this reason that specimens for HPV are often collected simultaneously with the PAP smear. The laboratory should be consulted about the availability of this option prior to specimen collection as specific test kits are required to allow for simultaneous sample collection. HPV infection can be successfully treated once it has been identified. Gardasil®, the first vaccine developed against HPV, is given at 2 and 6 mo respectively, after the initial injection. CDC recommends vaccination for females age 11 and 12 yr. Vaccination is also recommended for females age 13 to 26 yr who haven’t been previously vaccinated.

A wet prep can be prepared simultaneously from a cervical or vaginal sample. The swab is

</table>
touched to a microscope slide and a small amount of saline is dropped on the slide. The slide is examined by microscope to determine the presence of harmful bacteria or trichomonas.

A Schiller’s test entails applying an iodine solution to the cervix. Normal cells pick up the iodine and stain brown. Abnormal cells do not pick up any color.

Improvements in specimen preparation have added to the increased quality of screening procedures. The Cytyc ThinPrep PapTest (www.cytyc.com/), approved by the U.S. Food and Drug Administration in 1996, is a technique that provides a uniform monolayer of cells free of debris such as blood and mucus. Computerized scanning systems are also being used to reduce the number of smears that require manual review by a cytotechnologist or pathologist.

There are now some alternatives to cone biopsy and cryosurgery for the treatment of cervical dysplasia. Patients with abnormal Pap smear results may have a cervical loop electrosurgical excision procedure (LEEP) performed to remove or destroy abnormal cervical tissue. In the LEEP procedure, a speculum is inserted into the vagina, the cervix is numbed, and a special electrically charged wire loop is used to painlessly remove the suspicious area. Postprocedure cramping and bleeding can occur. Laser ablation is another technique that can be employed for the precise removal of abnormal cervical tissue.

**INDICATIONS:**
- Assist in the diagnosis of cervical dysplasia
- Assist in the diagnosis of endometriosis, condyloma, and vaginal adenosis
- Assist in the diagnosis of genital infections (herpes, Candida spp., Trichomonas vaginalis, cytomegalovirus, Chlamydia, lymphogranuloma venereum, HPV, and Actinomyces spp.)
- Assist in the diagnosis of primary and metastatic neoplasms
- Evaluate hormonal function

**RESULT:**

**Positive findings in:**
(See table [Bethesda system])

**Decreased in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- The smear should not be allowed to air dry before fixation.
- Lubricating jelly should not be used on the speculum.
- Improper collection site may result in specimen rejection. Samples for cancer screening are obtained from the posterior vaginal fornix and from the cervix. Samples for hormonal evaluation are obtained from the vagina.
- Douching, sexual intercourse, using tampons, or using vaginal medication within 24 hr prior to specimen collection can interfere with the specimen’s results.
- Collection of other specimens prior to the collection of the Pap smear may be cause for specimen rejection.
- Contamination with blood from samples collected during the patient’s menstrual period may be cause for specimen rejection.
NURSING IMPLICATIONS AND PROCEDURE

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is primarily used to establish a histological diagnosis of cervical and vaginal disease and identify the presence of genital infections.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient.
- Instruct the patient to avoid douching or sexual intercourse for 24 hr before specimen collection. Verify that the patient is not menstruating. Address concerns about pain and explain that there may be some discomfort during the procedure. Inform the patient that specimen collection is performed by a health care provider (HCP) specializing in this procedure and takes approximately 5 to 10 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- If the patient is taking vaginal antibiotic medication, testing should be delayed for 1 mo after the treatment has been completed.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Have the patient void before the procedure.
- Have the patient remove clothes below the waist.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to breathe normally and to avoid unnecessary movement during the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
- Assist the patient into a lithotomy position on a gynecological examination table (with feet in stirrups). Drape the patient’s legs.
- A plastic or metal speculum is inserted into the vagina and is opened to gently spread apart the vagina for inspection of the cervix. The speculum may be dipped in warm water to aid in comfortable insertion.
- After the speculum is properly positioned, the cervical and vaginal specimens are obtained. A synthetic fiber brush is inserted deep enough into the cervix to reach the endocervical canal. The brush is then rotated one turn and removed. A plastic or wooden spatula is used to lightly scrape the cervix and vaginal wall.

**Conventional Collection:**

- Both specimens that are on the brush and spatula are then plated on the glass slide. The brush specimen is plated using a gentle rolling motion, whereas the spatula specimen is plated using a light gliding motion across the slide. The specimens are immediately fixed to the slide with a liquid or spray containing 95% ethanol. The speculum is removed from the vagina. A pelvic and/or rectal exam is usually performed after specimen collection is completed.

**ThinPrep Collection:**

- The ThinPrep bottle lid is opened and removed, exposing the solution. The brush and spatula specimens are then gently swished in the ThinPrep solution.
to remove the adhering cells. The brush and spatula are then removed from the ThinPrep solution, and the bottle lid is replaced and secured.

**General:**
- Place samples in properly labeled specimen container and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Cleanse or allow the patient to cleanse secretions or excess lubricant (if a pelvic and/or rectal examination is also performed) from the perineal area. Provide a sanitary pad if cervical bleeding occurs.
- Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient, as appropriate, that repeat testing may be requested in the event of specimen rejection or abnormal findings. Inform the patient that non–sexually active women should begin yearly Pap smears at 18 yr of age, and younger sexually active women should begin yearly Pap smears earlier. Pap smears should be repeated more frequently if the results return abnormal. After a hysterectomy, a vaginal cuff Pap smear is used to monitor the cells lining the terminal end of the vagina. Several guidelines differ in their recommendations on when to cease Pap smear testing. Encourage older patients to discuss their Pap smear result history and women’s health history with their HCP to determine at what age testing may be terminated. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include biopsy cervical, cancer antigens, Chlamydia group antibody, colposcopy, culture anal/genital, culture throat, culture urine, culture viral, CMV, cytology urine, laparoscopy gynecologic, US pelvis, and UA.
- Refer to the Immune and Reproductive System tables at the back of the book for related tests by body system.

**Parathyroid Hormone: Intact, C-Terminal, and N-Terminal**

**SYNONYM/ACRONYM:** Parathormone, PTH.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Specimen should be transported tightly capped and in an ice slurry.

**REFERENCE VALUE:** (Method: Immunoassay)

Access additional resources at davisplus.fadavis.com
**DESCRIPTION:** Parathyroid hormone (PTH) is secreted by the parathyroid glands in response to decreased levels of circulating calcium. PTH assists in the mobilization of calcium from bone into the bloodstream, promoting renal tubular reabsorption of calcium and depression of phosphate reabsorption, thereby reducing calcium excretion and increasing phosphate excretion by the kidneys. PTH also decreases the renal secretion of hydrogen ions, which leads to increased renal excretion of bicarbonate and chloride. PTH enhances renal production of active vitamin D metabolites, causing increased calcium absorption in the small intestine. The net result of PTH action is maintenance of adequate serum calcium levels. In normal individuals, intact PTH has a circulating half-life of about 5 min. N-terminal PTH has a circulating half-life of about 2 min and is found in very small quantities. Intact and N-terminal PTH are the only biologically active forms of the hormone. Ninety percent of circulating PTH is composed of inactive C-terminal and midregion fragments. PTH is cleared from the body by the kidneys.

**INDICATIONS:**
- Assist in the diagnosis of hyperparathyroidism
- Assist in the diagnosis of suspected secondary hyperparathyroidism due to chronic renal failure, malignant tumors that produce ectopic PTH, and malabsorption syndromes
- Detect incidental damage or inadvertent removal of the parathyroid glands during thyroid or neck surgery
- Differentiate parathyroid and non-parathyroid causes of hypercalcemia
- Evaluate autoimmune destruction of the parathyroid glands
- Evaluate parathyroid response to altered serum calcium levels, especially those that result from malignant processes, leading to decreased PTH production
- Evaluate source of altered calcium metabolism

**RESULT:**

*Increased in:*
- Fluorosis (Skeletal fluorosis can cause a condition resembling secondary hyperparathyroidism, disruption in calcium homeostasis, and excessive PTH production)
- Primary, secondary, or tertiary hyperparathyroidism (All result in excess PTH production)

</table>
• Pseudogout (Calcium is lost due to deposits in the joint; decrease in calcium stimulates PTH production)
• Pseudohypoparathyroidism
• Zollinger-Ellison syndrome (Poor intestinal absorption of calcium and vitamin D; decreased calcium stimulates PTH production)

Decreased in:
• Autoimmune destruction of the parathyroids (Related to decreased parathyroid function)
• DiGeorge syndrome (Related to hypoparathyroidism)
• Hyperthyroidism (Related to increased calcium from bone loss; increased calcium levels inhibit PTH production)
• Hypomagnesemia (Magnesium is a calcium channel blocker; low magnesium levels allow for increased calcium which inhibits PTH production)
• Nonparathyroid hypercalcemia (in the absence of renal failure) (Increased calcium levels inhibit PTH production)
• Sarcoidosis (Related to increased calcium levels)
• Secondary hypoparathyroidism due to surgery

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may increase PTH levels include clodronate, dopamine, estrogen/progestin therapy, foscarnet, furosemide, hydrocortisone, isoniazid, lithium, octreotide, pamidronate, phosphates, prednisone, tamoxifen, and verapamil.
• Drugs and vitamins that may decrease PTH levels include alfalcacidol, aluminum hydroxide, calcitriol, cimetidine (C-terminal only), diltiazem, magnesium sulfate, pindolol, prednisone (intact), and vitamin D.
• PTH levels are subject to diurnal variation, with highest levels occurring in the morning.
• PTH levels should always be measured in conjunction with calcium for proper interpretation.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➧ Inform the patient that the test is used to assist in the diagnosis of parathyroid disease and disorders of calcium balance. It is also used to monitor patients undergoing renal dialysis.
➧ Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
➧ Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
➧ Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
➧ Review the procedure with the patient. Early-morning specimen collection is recommended because of the diurnal variation in PTH levels. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological...
support before, during, and after the procedure.
The patient should fast for 12 hr before specimen collection. Protocols may vary from facility to facility.
There are no fluid or medication restrictions, unless by medical direction.
Prepare an ice slurry in a cup or plastic bag to have on hand for immediate transport of the specimen to the laboratory.

**INTRATEST:**
- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 12 hr prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis. The sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume usual diet, as directed by the HCP.

**Nutritional considerations:** Patients with abnormal parathyroid levels are also likely to experience the effects of calcium level imbalances. Instruct the patient to report signs and symptoms of hypocalcemia and hypercalcemia to the HCP. (For critical values, signs, and symptoms of calcium imbalance, and nutritional information, see monographs titled “Calcium, Blood,” “Calcium, Ionized,” and “Calcium, Urine.”)

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ALP, arthroscopy, calcitonin, calcium, collagen cross-linked telopeptides, evoked brain potentials, fecal fat, gastric emptying scan, gastric acid stimulation, gastrin stimulation test, parathyroid scan, phosphorus, RAIU, synovial fluid analysis, TSH, thyroxine, US thyroid and parathyroid, uric acid, UA, and vitamin D.
- Refer to the Endocrine System table at the back of the book for related tests by body system.
Parathyroid Scan

SYNONYM/ACRONYM: Parathyroid scintiscan.

AREA OF APPLICATION: Parathyroid.

CONTRAST: IV technetium-99m (Tc-99m) pertechnetate, Tc-99m sestamibi, oral iodine-123, and thallium.

DESCRIPTION: Parathyroid scanning is performed to assist in the preoperative localization of parathyroid adenomas in clinically proven primary hyperparathyroidism; it is useful for distinguishing between intrinsic and extrinsic parathyroid adenomas. It is also performed after surgery to verify the presence of the parathyroid gland in children, and it is done after thyroidectomy as well.

The radionuclide is administered 10 to 20 min before the imaging is performed. The thyroid and surrounding tissues should be carefully palpated.

Fine-needle aspiration biopsy guided by ultrasound is occasionally necessary to differentiate thyroid pathology, as well as pathology of other tissues, from parathyroid neoplasia.

RESULT:

Normal findings in:
- No areas of increased perfusion or uptake in the thyroid or parathyroid

Abnormal findings in:
- Intrinsic and extrinsic parathyroid adenomas

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Ingestion of foods containing iodine (e.g., iodized salt) and medications containing iodine (e.g., cough syrup, potassium iodide, vitamins, Lugol's solution, thyroid replacement medications), which can decrease uptake of the radionuclide
- Other nuclear scans or iodinated contrast medium radiographic studies done within the previous 24 to 48 hr

INDICATIONS:
- Aid in the diagnosis of hyperparathyroidism
- Differentiate between extrinsic and intrinsic parathyroid adenoma, but not between benign and malignant conditions
- Evaluate the parathyroid in patients with severe hypercalcemia or in patients before parathyroidectomy
Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.

Other considerations:
- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures.

Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test. Inform the patient that the procedure is performed in a nuclear medicine department, usually by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the parathyroid glands.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, or anesthetics.
- Note any recent procedures that can interfere with test results, including examinations using iodinated contrast medium or radioactive nuclides.
- Obtain a history of results of the patient’s endocrine and immune systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.

Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Technetium-99m (Tc-99m) pertechnetate is injected IV before scanning.
- Place the patient in a supine position under a radionuclide gamma camera. Images are performed 15 min after the injection.
- With the patient in the same position, Tc-99m sestamibi is injected, and a second image is obtained after 10 min. Iodine-123 may be administered orally in place of Tc-99m pertechnetate; the
imaging sequence, as described previously, is performed 24 hr later.  
Remove the needle and apply a pressure dressing over the puncture site.

POST-TEST:
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the injection site.
- Advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- Instruct the patient to flush the toilet immediately and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include calcitonin, calcium, CT thoracic and MRI chest, PTH, phosphorus, and US thyroid and parathyroid.
- Refer to the Endocrine and Immune System tables in the back of the book for related tests by body system.

Partial Thromboplastin Time, Activated

SYNONYM/ACRONYM: aPTT, APTT.

SPECIMEN: Plasma (1 mL) collected in a completely filled blue-top (sodium citrate) tube.

REFERENCE VALUE: (Method: Clot detection) 25 to 39 sec. Reference ranges vary with respect to the equipment and reagents used to perform the assay.

Access additional resources at davisplus.fadavis.com
DESCRIPTION: The activated partial thromboplastin time (aPTT) coagulation test evaluates the function of the intrinsic (factors XII, XI, IX, and VIII) and common (factors V, X, II, and I) pathways of the coagulation sequence, specifically the intrinsic thromboplastin system. It represents the time required for a firm fibrin clot to form after tissue thromboplastin or phospholipid reagents similar to thromboplastin and calcium are added to the specimen. The aPTT is abnormal in 90% of patients with coagulation disorders and is useful in monitoring the inactivation of factor II effect of heparin therapy. The test is prolonged when there is a 30% to 40% deficiency in one of the factors required, or when factor inhibitors (e.g., antithrombin III, protein C, or protein S) are present. The aPTT has additional activators, such as kaolin, Celite, or elegiac acid, that more rapidly activate factor XII, making this test faster and more reliably reproducible than the partial thromboplastin time (PTT). A comparison between the results of aPTT and prothrombin time (PT) tests can allow some inferences to be made that a factor deficiency exists. A normal aPTT with a prolonged PT can only occur with factor VII deficiency. A prolonged aPTT with a normal PT could indicate a deficiency in factors XII, XI, IX, VIII, and VIII:C (von Willebrand factor). Factor deficiencies can also be identified by correction or substitution studies using normal serum. These studies are easy to perform and are accomplished by adding plasma from a normal patient to a sample from a patient suspected to be factor deficient. When the aPTT is repeated and is corrected, or within the reference range, it can be assumed that the prolonged aPTT is caused by a factor deficiency. If the result remains uncorrected, the prolonged aPTT is most likely due to a circulating anticoagulant. The administration of prophylactic low-dose heparin does not require serial monitoring of aPTT. (For more information on factor deficiencies, see monograph titled “Fibrinogen.”)

INDICATIONS:
• Detect congenital deficiencies in clotting factors, as seen in diseases such as hemophilia A (factor VIII) and hemophilia B (factor IX)
• Evaluate response to anticoagulant therapy with heparin or coumarin derivatives
• Identify individuals who may be prone to bleeding during surgical, obstetric, dental, or invasive diagnostic procedures
• Identify the possible cause of abnormal bleeding, such as epistaxis, hematoma, gingival bleeding, hematuria, and menorrhagia
• Monitor the hemostatic effects of conditions such as liver disease, protein deficiency, and fat malabsorption

RESULT:
Prolonged in:
• Afibrinogenemia (Fibrinogen is required for clotting and its absence will prolong aPTT)
• Circulating anticoagulants (Inhibitors of specific factors,
e.g., developed from long-term Factor VIII therapy or circulating anticoagulants associated with conditions like TB, SLE, RA, and chronic glomerulonephritis

- Circulating products of fibrin and fibrinogen degradation (Breakdown products of fibrin in circulation will prolong aPTT)
- Disseminated intravascular coagulation (Clotting factors are consumed and aPTT is prolonged)
- Factor deficiencies (Factors are required for clotting; in their absence aPTT will be prolonged)
- Hemodialysis patients (Heparin will prolong aPTT)
- Severe liver disease (Clotting factors are made in the liver; decreased liver function will result in decreased production of clotting factors and prolonged aPTT)
- Vitamin K deficiency (Vitamin K is required for clotting and its absence will prolong aPTT)
- Von Willebrand’s disease (Congenital deficiency of clotting factors that results in prolonged aPTT)

**CRITICAL VALUES:**
Greater than 70 seconds.

The requesting health care provider (HCP) should also be notified if the aPTT is less than 53 sec in a patient receiving heparin therapy. Low values indicate that the therapy is providing inadequate anticoagulation.

Note and immediately report to the HCP any critically increased or decreased values and related symptoms. Important signs to note are prolonged bleeding, hematoma at the puncture site, hemorrhage, blood in the stool, bleeding gums, and shock. Monitoring vital signs and neurological changes until values are within normal range is indicated. Administration of protamine sulfate may be requested.

**INTERFERING FACTORS:**
- Drugs and vitamins such as anistreplase, antihistamines, chlorpromazine, salicylates, and ascorbic acid may cause prolonged aPTT.
- Anticoagulant therapy with heparin will prolong the aPTT.
- Copper is a component of factor V, and severe copper deficiencies may result in prolonged aPTT values.
- Traumatic venipunctures can activate the coagulation sequence by contamination of the sample with tissue thromboplastin and can produce falsely shortened results.
- Failure to fill the tube sufficiently to yield a proper blood-to-anticoagulant ratio invalidates the results and is reason for specimen rejection.
- Excessive agitation that causes sample hemolysis can falsely shorten the aPTT because the hemolyzed cells activate plasma-clotting factors.
- Inadequate mixing of the tube can produce erroneous results.
- Specimens left unprocessed for longer than 4 hr should be rejected for analysis.
- High platelet count or inadequate centrifugation will result in decreased values.
- Hematocrit greater than 55% may cause falsely prolonged results because of anticoagulant excess. The excess anticoagulant excesses the calcium reagent in the test system, making it unavailable to react properly with the patient sample.
PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate coagulation disorders and monitor therapy.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s respiratory system, especially any bleeding disorders and other symptoms, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. If the patient is receiving anticoagulant therapy, note the time and amount of the last dose.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. Fill the tube completely. Important note: Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It is important to ask the laboratory which concentration it recommends, because each concentration will have its own specific reference range.
- When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and red-top tubes. When coagulation testing is the only work to be done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with tissue thromboplastin.
- Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed specimens stored in unopened tubes is that testing should be completed within 1 to 4 hr of collection.

POST-TEST:

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to report severe bruising or bleeding from any areas of the skin or mucous membranes.
- Inform the patient with prolonged aPTT values of the importance of taking precautions against bruising and bleeding, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of acetylsalicylic acid and similar products, and avoidance of intramuscular injections.
- Inform the patient of the importance of periodic laboratory testing while taking an anticoagulant.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address
Parvovirus B19 Immunoglobulin G and Immunoglobulin M Antibodies

SYNONYM/ACRONYM: N/A.

SPECIMEN: Serum (2 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Immunoassay)

**Negative** Less than 0.8
**Equivocal** 0.8–1.2

DESCRIPTION: Parvovirus B19, a single-stranded DNA virus transmitted by respiratory secretions, is the only parvovirus known to infect humans. Its primary site of replication is in red blood cell precursors in the bone marrow. It is capable of causing disease along a wide spectrum ranging from a self-limited erythema (fifth disease) to bone marrow failure or aplastic crisis in patients with sickle cell anemia, spherocytosis, or thalassemia. Fetal hydrops and spontaneous abortion may also occur as a result of infection during pregnancy. The incubation period is approximately 1 wk after exposure. B19-specific antibodies appear in the serum approximately 3 days after the onset of symptoms. The presence of immunoglobulin M (IgM) antibodies indicates acute infection. The presence of immunoglobulin G (IgG) antibodies indicates past infection and is believed to confer lifelong immunity. Parvovirus B19 can also be detected by DNA hybridization using a polymerase chain reaction.

INDICATIONS:
- Assist in establishing a diagnosis of parvovirus B19 infection

RESULT:

Positive findings in:
Parvovirus infection can be evidenced in a variety of conditions.
- Arthritis
- Erythema infectiosum (fifth disease)

Access additional resources at davisplus.fadavis.com
• Erythrocyte aplasia
• Hydrops fetalis

**Negative findings in:**

**CRITICAL VALUES:**
Greater than 60 sec

Note and immediately report to the health care provider (HCP) any critically increased values and related symptoms. Important signs to note are prolonged bleeding from cuts or gums, hematoma at a puncture site, hemorrhage, blood in the stool, persistent epistaxis, heavy or prolonged menstrual flow, and shock. Monitor vital signs, unusual ecchymosis, occult blood, severe headache, unusual dizziness, and neurological changes until aPTT is within normal range.

**INTERFERING FACTORS:**
• Immunocompromised patients may not develop sufficient antibody to be detected.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
• If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
• Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
• Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
• Remove the needle, and apply a pressure dressing over the puncture site.
• Promptly transport the specimen to the laboratory for processing and analysis.
• Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

**PRETEST:**
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to assist in confirming past or present parvovirus infection.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Inform the patient that a subsequent sample will be required in 7 to 14 days. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

**POST-TEST:**
• A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
• Recognize anxiety related to test results, and be supportive of impaired activity related to lack of neuromuscular control, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
• Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Emphasize the need for the patient to return to have a convalescent blood sample taken in 7 to 14 days. Answer any questions or address any concerns voiced by the patient or family.
**Pericardial Fluid Analysis**

**SYNONYM/ACRONYM:** None.

**SPECIMEN:** Pericardial fluid (5 mL) collected in a red- or green-top (heparin) tube for glucose, a lavender-top (EDTA) tube for cell count, and sterile containers for microbiology specimens; 200 to 500 mL of fluid in a clear container for cytology. Ensure that there is an equal amount of fixative and fluid in the container for cytology.

**REFERENCE VALUE:** (Method: Spectrophotometry for glucose; automated or manual cell count, macroscopic examination of cultured organisms, and microscopic examination of specimen for microbiology and cytology; microscopic examination of cultured microorganisms)

**DESCRIPTION:** The heart is located within a protective membrane called the *pericardium*. The fluid between the pericardial membranes is called *serous fluid*. Normally only a small amount of fluid is present because the rates of fluid production and absorption are about the same. Many abnormal conditions can result in the buildup of fluid within the pericardium. Specific tests are usually ordered in addition to a common battery of tests used to distinguish a transudate from an exudate. *Transudates* are effusions that form as a...
result of a systemic disorder that disrupts the regulation of fluid balance, such as a suspected perforation. **Exudates** are caused by conditions involving the tissue of the membrane itself, such as an infection or malignancy. Fluid is withdrawn from the pericardium by needle aspiration and tested as listed in the previous and following tables.

LDH = lactate dehydrogenase.

**INDICATIONS:**
- Evaluate effusion of unknown etiology
- Investigate suspected hemorrhage, immune disease, malignancy, or infection

**RESULT:**

**Increased in:**

**Increased in (condition/test showing increased result):**
- Bacterial pericarditis (red blood cell [RBC] count, white blood cell [WBC] count with a predominance of neutrophils)
- Hemorrhagic pericarditis (RBC count, WBC count)
- Malignancy (RBC count, abnormal cytology)
- Post–myocardial infarction syndrome, also called Dressler’s syndrome (RBC count, WBC count with a predominance of neutrophils)
- Rheumatoid disease or systemic lupus erythematosus (SLE) (RBC count, WBC count)
- Tuberculous or fungal pericarditis (RBC count, WBC count with a predominance of lymphocytes)
- Viral pericarditis (RBC count, WBC count with a predominance of neutrophils)

**Decreased in:**

**Decreased in (condition/test showing decreased result):**
- Bacterial pericarditis (glucose)
- Malignancy (glucose)
- Rheumatoid disease or SLE (glucose)

**CRITICAL VALUES:**
Note and immediately report to the health care provider (HCP) positive culture results, if ordered, and related symptoms.

**INTERFERING FACTORS:**
- Bloody fluid may be the result of a traumatic tap.
- Unknown hyperglycemia or hypoglycemia may be misleading in the comparison of fluid and serum glucose levels. Therefore, it is advisable to collect comparative serum samples a few hr before performing pericardiocentesis.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is primarily used to classify the type of effusion being produced and identify the cause of its accumulation.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s respiratory system, especially any bleeding disorders and other symptoms, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to the surgical procedure.
- Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to needle insertion through the chest wall. Explain to the patient that any discomfort with the needle insertion will be minimized with local anesthetics and systemic analgesics. Explain that the anesthetic injection may cause a stinging sensation. Explain that, after the skin has been anesthetized, a large needle will be inserted through the chest to obtain the fluid. Inform the patient that specimen collection is performed by a HCP specializing in this procedure and it usually takes approximately 30 min to complete.
- Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. Food and fluids should be restricted for 6 to 8 hr before the procedure, as directed by the HCP, unless the procedure is performed in an emergency situation to correct pericarditis. The requesting HCP may request that anticoagulants and aspirin be withheld. The number of days to withhold medication is dependent on the type of anticoagulant. Protocols may vary from facility to facility.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:
- Ensure that the patient has complied with dietary and fluids restrictions; assure that food has been restricted for at least 6 to 8 hr prior to the procedure.
- Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Notify HCP if patient anticoagulant therapy has not been withheld.
- Have emergency equipment readily available.
- Have the patient void before the procedure.
- Have the patient remove clothes above the waist and put on a gown.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the
corresponding patient demographics, date and time of collection, and site location.

- Establish an IV line to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.
- Assist the patient into a comfortable supine position with the head elevated 45° to 60°.
- Prior to the administration of local anesthesia, cleanse the site with an antiseptic solution, and drape the area with sterile towels. The skin at the injection site is then anesthetized.
- The precordial (V) cardiac lead wire is attached to the cardiac needle with an alligator clip. The cardiac needle is inserted just below and to the left of the breastbone, and fluid is removed.
- Monitor vital signs every 15 min for signs of hypovolemia or shock. Monitor electrocardiogram for needle-tip positioning to indicate accidental puncture of the right atrium.
- The needle is withdrawn, and slight pressure is applied to the site. Apply a sterile dressing to the site.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- Place samples in properly labeled specimen containers, and promptly transport the specimens to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet and medications, as directed by the HCP.
- Monitor vital signs and cardiac status every 15 min for the first hour, every 30 min for the next 2 hr, every hr for the next 4 hr, and every 4 hr for the next 24 hr. Take the patient’s temperature every 4 hr for 24 hr. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Observe the patient for signs of respiratory and cardiac distress, such as shortness of breathe, cyanosis, or rapid pulse.

- Continue IV fluids until vital signs are stable and the patient can resume fluid intake independently.
- Inform the patient that 1 hr or more of bed rest is required after the procedure.
- Assess the puncture site for bleeding or drainage and signs of inflammation each time vital signs are taken and daily thereafter for several days. Report to HCP if bleeding is present.
- Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- Administer antibiotics, as ordered, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.
- Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, if appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include AST, atrial natriuretic peptide, blood gases, B-type natriuretic peptide, cancer antigens, CEA and cancer antigens, chest x-ray, complete blood count, WBC count and differential, CK and isoenzymes, culture and smear mycobacteria, culture blood, culture fungal, culture viral, ECG, echocardiography, α₁-fetoprotein, homocysteine, LDH and isoenzymes, magnesium, MRI chest, MI scan, myoglobin, and troponin.
- Refer to the Cardiovascular and Immune System tables at the back of the book for related tests by body system.
Peritoneal Fluid Analysis

SYNONYM/ACRONYM: Ascites fluid analysis.

SPECIMEN: Peritoneal fluid (5 mL) collected in a red- or green-top (heparin) tube for amylase, glucose, and alkaline phosphatase; lavender-top (EDTA) tube for cell count; sterile containers for microbiology specimens; 200 to 500 mL of fluid in a clear container with anticoagulant for cytology. Ensure that there is an equal amount of fixative and fluid in the container for cytology.

REFERENCE VALUE: (Method: Spectrophotometry for glucose, amylase, and alkaline phosphatase; automated or manual cell count, macroscopic examination of cultured organisms, and microscopic examination of specimen for microbiology and cytology; microscopic examination of cultured microorganisms)

DESCRIPTION: The peritoneal cavity and organs within it are lined with a protective membrane. The fluid between the membranes is called serous fluid. Normally only a small amount of fluid is present because the rates of fluid production and absorption are about the same. Many abnormal conditions can result in the buildup of fluid within the peritoneal cavity. Specific tests are usually ordered in addition to a common battery of tests used to distinguish a transudate from an exudate. Transudates are effusions that form as a result of a systemic disorder that disrupts the regulation of fluid balance, such as a suspected perforation. Exudates are caused by conditions involving the tissue of the membrane itself, such as an infection or malignancy. Fluid is withdrawn from the peritoneal cavity by needle aspiration and tested as listed in the previous and following tables.

INDICATIONS:
- Evaluate ascites of unknown cause
- Investigate suspected peritoneal rupture, perforation, malignancy, or infection

Access additional resources at davisplus.fadavis.com
RESULT:

**Increased in:**

**Increased in (condition/test showing increased result):**

- Abdominal malignancy (red blood cell [RBC] count, carcinoembryonic antigen, abnormal cytology)
- Abdominal trauma (RBC count greater than 100,000/mm³)
- Ascites caused by cirrhosis (white blood cell [WBC] count, neutrophils greater than 25% but less than 50%, absolute granulocyte count greater than 250/mm³)
- Bacterial peritonitis (WBC count, neutrophils greater than 50%, absolute granulocyte count greater than 250/mm³)
- Peritoneal effusion due to gastric strangulation, perforation, or necrosis (amylase, ammonia, alkaline phosphatase)
- Peritoneal effusion due to pancreatitis, pancreatic trauma, or pancreatic pseudocyst (amylase)
- Rupture or perforation of urinary bladder (ammonia, creatinine, urea)
- Tuberculous effusion (elevated lymphocyte count, positive acid-fast bacillus smear and culture [25% to 50% of cases])

**Decreased in:**

**Decreased in (condition/test showing decreased result):**

- Abdominal malignancy (glucose)
- Tuberculous effusion (glucose)

**CRITICAL VALUES:**

Note and immediately report to the health care provider (HCP) positive culture results, if ordered, and related symptoms.

**INTERFERING FACTORS:**

- Bloody fluids may result from a traumatic tap.
- Unknown hyperglycemia or hypoglycemia may be misleading in the comparison of fluid and serum glucose levels. Therefore, it is advisable to collect comparative serum samples a few hr before performing paracentesis.

**Characteristic** | **Transudate** | **Exudate**
--- | --- | ---
Appearance | Clear | Cloudy or turbid

Fluid-to–serum protein ratio | Less than 0.5 | Greater than 0.5
LDH | Parallels serum value | Less than 200 units/L
Fluid-to–serum LDH ratio | Less than 0.6 | Greater than 0.6
Fluid cholesterol | Less than 55 mg/dL | Greater than 55 mg/dL
White blood cell count | Less than 100/mm³ | Greater than 1000/mm³

LDH = lactate dehydrogenase.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is primarily used to classify the type of effusion being produced and identify the cause of its accumulation.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s respiratory system, especially any bleeding disorders and other symptoms, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
Note any recent procedures that can interfere with test results.
Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
Review the procedure with the patient. If patient has ascites, obtain weight and measure abdominal girth. Inform the patient that it may be necessary to remove hair from the site before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to needle insertion through the abdomen wall. Explain to the patient that any discomfort with the needle insertion will be minimized with local anesthetics and systemic analgesics. Explain that the anesthetic injection may cause an initial stinging sensation. Explain that, after the skin has been anesthetized, a large needle will be inserted through the abdominal wall and a “popping” sensation may be experienced as the needle penetrates the peritoneum. Inform the patient that specimen collection is performed under sterile conditions by a HCP specializing in this procedure. The procedure usually takes approximately 30 min to complete.
Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
There are no food or fluid restrictions, unless by medical direction. The requesting HCP may request that anticoagulants and aspirin be withheld. The number of days to withhold medication is dependent on the type of anticoagulant.
Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:
Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Notify the HCP if patient anticoagulant therapy has not been withheld.
Have emergency equipment readily available.
Have the patient void or catheterize the patient to avoid accidental puncture of the bladder if he or she is unable to void.
Have the patient remove clothing and change into a gown for the procedure.
If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
Record baseline vital signs and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
Establish an IV line to allow infusion of IV fluids, antibiotics, analgesics, or IV sedation.
Assist the patient to a comfortable seated position with feet and back supported or in high Fowler’s position.
Prior to the administration of local anesthesia, shave and cleanse the site with an antiseptic solution, and drape the area with sterile towels. The skin at the injection site is then anesthetized.
The paracentesis needle is inserted 1 to 2 in. below the umbilicus, and fluid is removed. If lavage fluid is required (helpful if malignancy is suspected), saline or Ringer’s lactate can be infused via the needle over a 15- to 20-min period before the lavage fluid is removed. Monitor vital signs every 15 min for signs of hypovolemia or shock.

Access additional resources at davisplus.fadavis.com
No more than 1500 to 2000 mL of fluid should be removed at a time, even in the case of a therapeutic paracentesis, because of the risk of hypovolemia and shock.
The needle is withdrawn, and slight pressure applied to the site. Apply a sterile dressing to the site.
Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
Place samples in properly labeled specimen containers, and promptly transport the specimens to the laboratory for processing and analysis.

POST-TEST:
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
Instruct the patient to resume usual medications, as directed by the HCP.
Monitor vital signs every 15 min for the first hr, every 30 min for the next 2 hr, every hour for the next 4 hr, and every 4 hr for the next 24 hr. Take the patient’s temperature every 4 hr for 24 hr. Monitor intake and output for 24 hr. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
Assess the puncture site for bleeding or drainage and signs of inflammation each time vital signs are taken and daily thereafter for several days. Report to HCP if bleeding is present.
If a large amount of fluid was removed, obtain weight and measure abdominal girth.
Inform the patient that 1 hr or more of bed rest is required after the procedure.
Instruct the patient to immediately report severe abdominal pain (Note: rigidity of abdominal muscles indicates developing peritonitis).

Report to HCP if abdominal rigidity or pain is present.
Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
Administer antibiotics, as ordered, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.
Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, if appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
Related tests include CEA and cancer antigens, complete blood count, complete blood count, WBC count and differential, CT abdomen, CT biliary tract and liver, culture and smear mycobacteria, culture blood, culture fungal, culture viral, KUB studies, laparoscopy abdominal, liver and spleen scan, MRI abdomen, and US spleen.
Refer to the Gastrointestinal and Immune System tables at the back of the book for related tests by body system.
**Phosphorus, Blood**

**SYNONYM/ACRONYM:** Inorganic phosphorus, phosphate, PO₄

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

**REFERENCE VALUE:** (Method: Spectrophotometry)

**DESCRIPTION:** Phosphorus, in the form of phosphate, is distributed throughout the body. Approximately 85% of the body’s phosphorus is stored in bones; the remainder is found in cells and body fluids. It is the major intracellular anion and plays a crucial role in cellular metabolism, maintenance of cellular membranes, and formation of bones and teeth. Phosphorus also indirectly affects the release of oxygen from hemoglobin by affecting the formation of 2,3-bisphosphoglycerate. Levels of phosphorus are dependent on dietary intake.

Phosphorus excretion is regulated by the kidneys. Calcium and phosphorus are interrelated with respect to absorption and metabolic function. They have an inverse relationship with respect to concentration: serum phosphorus is increased when serum calcium is decreased. Hyperphosphatemia can result in an infant fed only cow’s milk during the first few weeks of life because of the combination of a high phosphorus content in cow’s milk and the inability of infants’ kidneys to clear the excess phosphorus.

**INDICATIONS:**
- Assist in establishing a diagnosis of hyperparathyroidism
- Assist in the evaluation of renal failure

**RESULT:**

*Increased in:*
- Acromegaly *(Related to increased renal absorption)*
- Bone metastases *(Related to release from bone stores)*
- Diabetic ketoacidosis *(Acid base imbalance that causes intracellular*
phosphorus to move into the extracellular fluid

• Excessive levels of vitamin D (Vitamin D promotes intestinal absorption of phosphorus; excessive levels promote phosphorus release from bone stores)
• Hyperthermia (Tissue damage causes intracellular phosphorus to be released into circulation)
• Hypocalcemia (Calcium and phosphorus have an inverse relationship)
• Hypoparathyroidism (Related to increased renal absorption)
• Lactic acidosis (Acid-base imbalance causes intracellular phosphorus to move into the extracellular fluid)
• Milk alkali syndrome (Increased dietary intake)
• Pseudohypoparathyroidism (Related to increased renal absorption)
• Pulmonary embolism (Related to respiratory acid-base imbalance and compensatory mechanisms)
• Renal failure (Related to decreased renal excretion)
• Respiratory acidosis (Acid-base imbalance that causes intracellular phosphorus to move into the extracellular fluid)

Decreased in:
• Acute gout
• Alcohol withdrawal
• Gram-negative bacterial septicemia
• Growth hormone deficiency
• Hyperalimentation therapy
• Hypercalcemia (Calcium and phosphorus have an inverse relationship)
• Hyperinsulinism (Insulin increases intracellular movement of phosphorus)
• Hyperparathyroidism (PTH increases renal excretion)
• Hypokalemia

• Impaired renal absorption (Decreases return of phosphorus to general circulation)
• Malabsorption syndromes (Insufficient intestinal absorption of phosphorus)
• Malnutrition (Deficient intake)
• Osteomalacia
• Parathyroid hormone–producing tumors (PTH increases renal excretion)
• Primary hyperparathyroidism (PTH increases renal excretion)
• Renal tubular acidosis
• Renal tubular defects (Decreased renal absorption)
• Respiratory alkalosis
• Respiratory infections
• Rickets (Related to vitamin D deficiency)
• Salicylate poisoning
• Severe burns
• Severe vomiting and diarrhea (Excessive loss)
• Vitamin D deficiency (Deficiency in vitamin D reduces intestinal and renal tubular absorption of phosphorus)

CRITICAL VALUES:

Values less than 1.0 mg/dL may have significant effects on the neuromuscular, gastrointestinal (GI), cardiopulmonary, and skeletal systems.

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms. Interventions including IV replacement therapy with sodium or potassium phosphate may be necessary. Close monitoring of both phosphorus and calcium is important during replacement therapy.

INTERFERING FACTORS:
• Drugs that may increase phosphorus levels include anabolic steroids, β-adrenergic blockers, ergocalciferol, furosemide, hydrochlorothiazide, methicillin (occurs with nephrotoxicity), oral
contraceptives, parathyroid extract, phosphates, sodium etidronate, tetracycline (occurs with nephrotoxicity), and vitamin D.

- Drugs that may decrease phosphorus levels include acetazolamide, albuterol, aluminum salts, amino acids (via IV hyperalimentation), anesthetic agents, anticonvulsants, calcitonin, epinephrine, fibrin hydrolysate, fructose, glucocorticoids, glucose, insulin, mannitol, oral contraceptives, pamidronate, phenothiazine, phytate, and plicamycin.
- Serum phosphorus levels are subject to diurnal variation: They are highest in late morning and lowest in the evening; therefore, serial samples should be collected at the same time of day for consistency in interpretation.
- Hemolysis will falsely increase phosphorus values.
- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, thereby falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is present in the IV solution, thereby falsely increasing the result.

**Nursing Implications and Procedure**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the general evaluation of multiple body systems.
- Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine, GI, genitourinary, and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Nutritional considerations: Severe hypophosphatemia is common in elderly patients or patients who have been hospitalized for long periods of time. Good dietary sources of phosphorus include meat, dairy products, nuts, and legumes.

Access additional resources at davisplus.fadavis.com
**Phosphorus, Urine**

**SYNONYM/ACRONYM:** Urine phosphate.

**SPECIMEN:** Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

**REFERENCE VALUE:** (Method: Spectrophotometry) Reference values are dependent on phosphorus and calcium intake. Phosphate excretion exhibits diurnal variation and is significantly higher at night.

<table>

**DESCRIPTION:** Phosphorus, in the form of phosphate, is distributed throughout the body. Approximately 85% of the body’s phosphorus is stored in bones; the remainder is found in cells and body fluids. It is the major intracellular anion and plays a crucial role in cellular metabolism, maintenance of cellular membranes, and formation of bones and teeth. Phosphorus also indirectly affects the release of oxygen from hemoglobin by...
affecting the formation of 2,3-bisphosphoglycerate. Levels of phosphorus are dependent on dietary intake.

Analyzing urinary phosphorus levels can provide important clues to the functioning of the kidneys and other major organs. Tests for phosphorus in urine usually involve timed urine collections over a 12- or 24-hr period. Measurement of random specimens may also be requested. Children with thalassemia may have normal phosphorus absorption but increased excretion, which may result in a phosphorus deficiency.

INDICATIONS:
• Assist in the diagnosis of hyperparathyroidism
• Assist in the evaluation of calcium and phosphorus balance
• Assist in the evaluation of nephrolithiasis
• Assist in the evaluation of renal tubular disease

RESULT:

Increased in:
• Abuse of diuretics (Increased renal excretion)
• Primary hyperparathyroidism (PTH increases renal excretion)
• Renal tubular acidosis
• Vitamin D deficiency (Decreased renal reabsorption)

Decreased in:
• Hypoparathyroidism (PTH enhances renal excretion, therefore a lack of PTH will decrease urine phosphorus levels)
• Pseudohypoparathyroidism (PTH enhances renal reabsorption, therefore a lack of response to PTH as in pseudohypoparathyroidism will decrease urine phosphorus levels)
• Vitamin D intoxication (Vitamin D promotes renal excretion of phosphorus)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs and vitamins that can cause an increase in urine phosphorus levels include acetazolamide, acetylsalicylic acid, alanine, bismuth salts, calcitonin, corticosteroids, dihydrotachysterol, glycine, hydrochlorothiazide, metolazone, parathyroid extract, parathyroid hormone, phosphates, tryptophan, valine, and vitamin D.
• Drugs that can cause a decrease in urine phosphorus levels include aluminum-containing antacids.
• Urine phosphorus levels are subject to diurnal variation: Output is highest in the afternoon, which is why 24-hr urine collections are recommended.
• All urine voided for the timed collection period must be included in the collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to evaluate calcium and phosphorus balance.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s endocrine and genitourinary systems.

Access additional resources at davisplus.fadavis.com
sensitivities, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.

- **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

- **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to avoid excessive exercise and stress during the 24-hr collection of urine.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

- Ensure that the patient has complied with activity restrictions and pretesting preparations; assure that excessive exercise and stress have been restricted during the 24-hr procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection.

**Random Specimen (Collect in Early Morning):**

- **Clean-Catch Specimen:**
  - Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
  - Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

- **Indwelling Catheter:**
  - Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

- **Timed Specimen:**
  - Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
  - Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
  - If an indwelling catheter is in place, replace the tubing and container.
Increased urine phosphorus levels may be associated with the formation of kidney stones. Educate the patient, if appropriate, on the importance of drinking a sufficient amount of water when kidney stones are suspected.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

Related tests include ALP, calcitonin, calcium, calculus kidney stone panel, chloride, CT abdomen, cystoscopy, IVP, KUB studies, PTH, parathyroid scan, phosphorus blood, potassium, renogram, retrograde ureteropyelography, uric acid, and UA.

Refer to the Endocrine and Genitourinary System tables at the back of the book for related tests by body system.

**Plasminogen**

**SYNONYM/ACRONYM:** Profibrinolysin, PMG.

**SPECIMEN:** Plasma (1 mL) collected in blue-top (sodium citrate) tube.

**REFERENCE VALUE:** (Method: Chromogenic substrate) 80% to 120% of normal for plasma.
DESCRIPTION: Plasminogen is a plasma glycoprotein. It is the circulating, inactive precursor to plasmin. Damaged tissues release a substance called plasminogen activator that initiates the conversion of plasminogen to plasmin. Plasmin participates in fibrinolysis and is capable of degrading fibrin, factor I (fibrinogen), factor V, and factor VIII. (For more information on fibrin degradation, see monograph titled “Fibrinogen.”)

INDICATIONS: Evaluate the level of circulating plasminogen in patients with thrombosis or disseminated intravascular coagulation (DIC).

RESULT: 

Increased in:  
• Pregnancy (late) *(Pathophysiology is not well understood)*

Decreased in:  
• DIC *(Levels decrease as it is consumed during the hyperfibrinolytic state by conversion to plasmin)*  
• Fibrinolytic therapy with tissue plasminogen activators such as streptokinase or urokinase *(Levels decrease as it is consumed during the therapy by conversion to plasmin)*  
• Hereditary deficiency  
• Liver disease *(Related to decreased production by damaged liver cells)*  
• Neonatal hyaline membrane disease *(Possibly related to deficiency of plasminogen)*  
• Postsurgical period *(Possibly related to trauma of surgery)*

CRITICAL VALUES: N/A

INTERFERING FACTORS:  
Drugs that may decrease plasminogen levels include streptokinase and urokinase.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:  
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.  
• Inform the patient that the test is used to evaluate thrombotic disorders and monitor thrombolytic therapy.  
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.  
• Obtain a history of the patient’s hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.  
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.  
• Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.  
• Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.  
• There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:  
• If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.  
• Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.  
• Observe standard precautions and follow the general guidelines in Appendix A. Positively identify the
patient and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. **Important note:** Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It is important to ask the laboratory which concentration it recommends, because each concentration will have its own specific reference range.

When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and red-top tubes. When coagulation testing is the only work to be done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with tissue thromboplastin, which can falsely decrease values.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed samples stored in unopened tubes is that testing should be completed within 1 to 4 hr of collection. If the patient has a known hematocrit above 55%, adjust the amount of anticoagulant in the collection tube before drawing the blood according to the CLSI guidelines:

\[
\text{Anticoagulant vol. [x]} = \frac{(100 - \text{hematocrit})}{(595 - \text{hematocrit})} \times \text{total vol. of anticoagulated blood required}
\]

**Example:**

Patient hematocrit = 60% (100 - 60)/(595 - 60) × 5.0 = 0.37 mL sodium citrate for a 5 mL standard drawing tube

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
- Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include AT-III, complete blood count, platelet count, coagulation factors, FDP, fibrinogen, aPTT, protein S, and PT/INR.
- Refer to the Hematopoietic System table at the back of the book for related tests by body system.
Platelet Antibodies

SYNONYM/ACRONYM: Antiplatelet antibody; platelet-bound IgG/IgM, direct and indirect.

SPECIMEN: Serum (1 mL) collected in a red-top tube for indirect immunoglobulin G (IgG) antibody. Whole blood (7 mL) collected in lavender-top (EDTA) tube for direct antibody.

REFERENCE VALUE: (Method: Solid-phase hemagglutination and flow cytometry) Negative.

DESCRIPTION: Platelet antibodies can be formed by autoimmune response, or they can be acquired in reaction to transfusion products. Platelet autoantibodies are immunoglobulins of autoimmune origin (i.e., immunoglobulin G [IgG]), and they are present in various autoimmune disorders, including thrombocytopenias. Platelet alloantibodies develop in patients who become sensitized to platelet antigens of transfused blood. As a result, destruction of both donor and native platelets occurs along with a shortened survival time of platelets in the transfusion recipient. The platelet antibody detection test is also used for platelet typing, which allows compatible platelets to be transfused to patients with disorders such as aplastic anemia and cancer. Platelet typing decreases the alloimmunization risk resulting from repeated transfusions from random donors. Platelet typing may also provide additional support for a diagnosis of post-transfusional purpura.

RESULT:

Increased in:
Development of platelet antibodies is associated with autoimmune conditions and medications.
- AIDS
- Acute myeloid leukemia
- Idiopathic thrombocytopenic purpura (Related to development of platelet-associated IgG antibodies)
- Immune complex diseases
- Multiple blood transfusions (Related in most cases to sensitization to PLA1 antigens on donor red blood cells that will stimulate formation of antiplatelet antibodies)
- Multiple myeloma
- Neonatal immune thrombocytopenia (Related to maternal platelet–associated antibodies directed against fetal platelets)
- Paroxysmal hemoglobinuria
- Rheumatoid arthritis
- Systemic lupus erythematosus
- Thrombocytopenias provoked by drugs (see monograph titled “Complete Blood Count, Platelet Count”)

Decreased in: N/A

CRITICAL VALUES: N/A
INTERFERING FACTORS:
Hemolyzed or clotted specimens will affect results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate thrombocytopenia.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, and inform the appropriate health care provider (HCP) accordingly.
- Obtain a history of the patient’s hematopoietic and immune systems, especially any bleeding disorders and other symptoms, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting HCP who will discuss the results with the patient.
- Note the patient’s response to platelet transfusions.
- Instruct the patient to report severe bruising or bleeding from any areas of the skin or mucous membranes.
- Inform the patient who has developed platelet antibodies of the importance of taking precautions against bruising and bleeding, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of acetylsalicylic acid and similar products, and avoidance of intramuscular injections.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include angiography abdominal, biopsy bone marrow, bleeding time, clot retraction, complete blood count, platelet count, CT brain, Ham’s test, hemosiderin, and LAP.
- Refer to the Hematopoietic and Immune System tables at the back of the book for related tests by body system.
Plethysmography

SYNONYM/ACRONYM: Impedance plethysmography, PVR.

AREA OF APPLICATION: Veins, arteries, and lungs.

CONTRAST: None.

DESCRIPTION: Plethysmography is a noninvasive diagnostic manometric study used to measure changes in the size of blood vessels by determining volume changes in the blood vessels of the eye, extremities, and neck; or to measure gas volume changes in the lungs.

Arterial plethysmography assesses arterial circulation in an upper or lower limb; it is used to diagnose extremity arteriosclerotic disease and to rule out occlusive disease. The test requires a normal extremity for comparison of results. The test is performed by applying a series of three blood pressure cuffs to the extremity. The amplitude of each pulse wave is then recorded.

Venous plethysmography, done with a series of cuffs, measures changes in venous capacity and outflow (volume and rate of outflow); it is used to diagnose a thrombotic condition that causes obstruction of the major veins of the extremity. When the cuffs are applied to an extremity in patients with venous obstruction, no initial increase in leg volume is recorded because the venous volume of the leg cannot dissipate quickly.

Body plethysmography measures the total amount (volume) of air within the thorax, whether or not the air is in ventilatory communication with the lung; the elasticity (compliance) of the lungs; and the resistance to airflow in the respiratory tree. It is used in conjunction with pulmonary stress testing and pulmonary function testing.

Impedance plethysmography is widely used to detect acute deep vein thrombosis (DVT) of the leg, but it can also be used in the arm, abdomen, neck, or thorax. Doppler flow studies now are used to identify DVT, but ultrasound studies are less accurate in examinations below the knee.

INDICATIONS:

Arterial Plethysmography:
• Confirm suspected acute arterial embolization
• Detect vascular changes associated with Raynaud’s phenomenon and disease
• Determine changes in toe or finger pressures when ankle pressures are elevated as a result of arterial calcifications
• Determine the effect of trauma on the arteries in an extremity
• Determine peripheral small-artery changes (ischemia) caused by diabetes, and differentiate these changes from neuropathy
• Evaluate suspected arterial occlusive disease
• Locate and determine the degree of arterial atherosclerotic obstruction and vessel patency in peripheral atherosclerotic disease, as well
as inflammatory changes causing obliteration in the vessels in thromboangiitis obliterans

**Venous Plethysmography:**
- Detect partial or total venous thrombotic obstruction
- Determine valve competency in conjunction with Doppler ultrasound in the diagnosis of varicose veins

**Body Plethysmography:**
- Detect acute pulmonary disorders, such as atelectasis
- Detect or determine the status of chronic obstructive pulmonary disease (COPD), such as emphysema, asthma, or chronic bronchitis
- Detect or determine the status of restrictive pulmonary disease, such as fibrosis
- Detect infectious pulmonary diseases, such as pneumonia
- Determine baseline pulmonary status before pulmonary rehabilitation to determine potential therapeutic benefit
- Differentiate between obstructive and restrictive pulmonary pathology

**Impedance Plethysmography:**
- Act as a diagnostic screen for patients at risk for DVT
- Detect and evaluate DVT
- Evaluate degree of resolution of DVT after treatment
- Evaluate patients with suspected pulmonary embolism (most pulmonary emboli are complications of DVT in the leg)

**Result:**

**Normal findings in:**
- Arterial plethysmography:  
  *Normal arterial pulse waves:* steep upslope, more gradual downslope with narrow pointed peaks  
  *Normal pressure:* less than 20 mm Hg systolic difference between the lower and upper extremities; toe pressure greater than or equal to 80% of ankle pressure, and finger pressure greater than or equal to 80% of wrist pressure
- Venous plethysmography:  
  *Normal venous blood flow in the extremities*  
  *Venous filling times greater than 20 sec*
- Body plethysmography:  
  *Thoracic gas volume:* 2400 mL  
  *Compliance:* 0.2 L/cm H$_2$O  
  *Airway resistance:* 0.6 to 2.5 cm H$_2$O/L per sec
- Impedance plethysmography:  
  *Sharp rise in volume with temporary occlusion*  
  *Rapid venous outflow with release of the occlusion*

**Abnormal findings in:**
- COPD, restrictive lung disease, lung infection, or atelectasis (body plethysmography)
- DVT (arterial, venous, or impedance plethysmography)
- Incompetent valves, thrombosis, or thrombotic obstruction in a major vein in an extremity
- Small-vessel diabetic changes
- Vascular disease (Raynaud’s phenomenon)
- Vascular trauma

**Critical values:**
- DVT

Note and immediately report to the health care provider (HCP) positive results and related symptoms.

**Interfering factors:**

**Arterial Plethysmography:**
- Cigarette smoking 2 hr before the study, which causes inaccurate results because the nicotine constricts the arteries
- Alcohol consumption
- Low cardiac output
- Shock

Access additional resources at davisplus.fadavis.com
Compression of pelvic veins (tumors or external compression by dressings)
- Environmental temperatures (hot or cold)
- Arterial occlusion proximal to the extremity to be examined, which can prevent blood flow to the limb

**Venous Plethysmography:**

*Factors that may impair results of the examination:*
- Low environmental temperature or cold extremity, which constricts the vessels
- High anxiety level or muscle tenseness
- Venous thrombotic occlusion proximal to the extremity to be examined, which can affect blood flow to the limb

**Body Plethysmography:**

*Factors that may impair results of the examination:*
- Inability of the patient to follow breathing instructions during the procedure

**Impedance Plethysmography:**

*Factors that may impair results of the examination:*
- Movement of the extremity during electrical impedance recording, poor electrode contact, or non-linear electrical output, which can cause false-positive results
- Constricting clothing or bandages

---

**Nursing Implications and Procedure**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

---

**INTRATEST:**
- Ensure the patient has refrained from smoking for 2 hr before the procedure.
- Instruct the patient to void prior to the procedure and to change into the
gown, robe, and foot coverings provided.

Obtain and record baseline vital signs.

Instruct the patient to report any unexpected symptoms that occur during the test.

Observe standard precautions, and follow the general guidelines in Appendix A.

**Arterial Plethysmography:**
- Explain to the patient that cuffs are applied to the extremity to measure and compare blood flow.
- Place the patient in a semi-Fowler position on an examining table or in bed.
- Ask the patient to notify medical personnel if he or she has unexpected symptoms during the test.
- Instruct the patient to remain still during the procedure.
- Apply three blood pressure cuffs to the extremity and attach a pulse volume recorder (plethysmograph), which records the amplitude of each pulse wave.
- Inflate the cuffs to 65 mm Hg to measure the pulse waves of each cuff. When compared with a normal limb, these measurements determine the presence of arterial occlusive disease.

**Venous Plethysmography:**
- Explain to the patient that cuffs are applied to the extremity to measure and compare blood flow.
- Place the patient in a semi-Fowler position on an examining table or in bed.
- Instruct the patient to remain still during the procedure.
- Apply two blood pressure cuffs to the extremity, one on the proximal part of the extremity (occlusion cuff) and the other on the distal part of the extremity (recorder cuff). Attach a third cuff to the pulse volume recorder.
- Inflate the recorder cuff to 10 mm Hg, and evaluate the effects of respiration on venous volume: Absence of changes during respirations indicates venous thrombotic occlusion.
- Inflate the occlusion cuff to 50 mm Hg, and record venous volume on the pulse monitor. Deflate the occlusion cuff after the highest volume is recorded in the recorder cuff. A delay in the return to preocclusion volume indicates venous thrombotic occlusion.

**Body Plethysmography:**
- Place the patient in a sitting position on a chair in the body box. Explain to the patient that the cuffs are applied to the extremities to measure and compare blood flow.
- Position a nose clip to prevent breathing through the nose, and connect a mouthpiece to a measuring instrument.
- Ask the patient to breathe through the mouthpiece.
- Close the door to the box, and record the start time of the procedure. At the beginning of the study, instruct the patient to pant rapidly and shallowly, without allowing the glottis to close.
- For compliance testing, a double-lumen nasoesophageal catheter is inserted, and the bag is inflated with air. Intraesophageal pressure is recorded during normal breathing.

**Impedance Plethysmography:**
- Explain to the patient that cuffs are applied to the extremity to measure and compare blood flow.
- Place the patient on his or her back with the leg being tested above the heart level.
- Flex the patient’s knee slightly, and rotate the hips by shifting weight to the same side as the leg being tested.
- Apply conductive gel and electrodes to the legs, near the cuffs.
- Apply a blood pressure cuff to the thigh.
- Inflate the pressure cuff attached to the thigh temporarily to occlude venous return without interfering with arterial blood flow. Expect the blood volume in the other calf to increase.
- A tracing of changes in electrical impedance occurring during inflation and for 15 sec after cuff deflation is recorded.
- With DVT, blood volume increases less than expected because the veins are already at capacity.

**POST-TEST:**
- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Remove conductive gel and electrodes, as applied.
Instruct the patient to resume usual activity and diet, as directed by the HCP.
Monitor for severe ischemia, ulcers, and pain of the extremity after arterial, venous, or impedance plethysmography, and handle the extremity gently.
Monitor respiratory pattern after body plethysmography, and allow the patient time to resume a normal breathing pattern.
Monitor vital signs every 15 minutes until they return to baseline levels.
Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include α1-AT, angiography pulmonary, anion gap, arterial/venous oxygen ratio, AT-III, biopsy lung, blood gases, bronchoscopy, carboxyhemoglobin, cardiopulmonary, chest x-ray, chloride sweat, cold agglutinin, complete blood count, complete blood count, hemoglobin, complete blood count, WBC count and differential, CT angiography, CT thoracic, culture and smear for mycobacteria, culture bacterial sputum, culture viral, cytology sputum, d-dimer, echocardiography, ECG, EMG, ENG, fibrinogen, gram stain, IgE, lactic acid, lung perfusion scan, lung ventilation scan, lupus anticoagulant antibodies, MR angiography, MRI chest, osmolality, phosphorus, plasminogen, pleural fluid analysis, potassium, PET chest, PFT, pulse oximetry, sodium, TB skin test, and US arterial and venous Doppler of the extremities.
- Refer to the Cardiovascular and Pulmonary System table in the back of the book for related tests by body system.

---

**Pleural Fluid Analysis**

**SYNONYM/ACRONYM:** Thoracentesis fluid analysis.

**SPECIMEN:** Pleural fluid (5 mL) collected in a green-top (heparin) tube for amylase, cholesterol, glucose, lactate dehydrogenase (LDH), pH, protein, and triglycerides; lavender-top (EDTA) tube for cell count; sterile containers for microbiology specimens; 200 to 500 mL of fluid in a clear container with anticoagulant for cytology. Ensure that there is an equal amount of fixative and fluid in the container for cytology.

**REFERENCE VALUE:** (Method: Spectrophotometry for amylase, cholesterol, glucose, LDH, protein, and triglycerides; ion-selective electrode for pH; automated or manual cell count; macroscopic and microscopic examination of cultured microorganisms; microscopic examination of specimen for microbiology and cytology.)
The pleural cavity and organs within it are lined with a protective membrane. The fluid between the membranes is called serous fluid. Normally only a small amount of fluid is present because the rates of fluid production and absorption are about the same. Many abnormal conditions can result in the buildup of fluid within the pleural cavity. Specific tests are usually ordered in addition to a common battery of tests used to distinguish a transudate from an exudate. Transudates are effusions that form as a result of a systemic disorder that disrupts the regulation of fluid balance, such as a suspected perforation. Exudates are caused by conditions involving the tissue of the membrane itself, such as an infection or malignancy. Fluid is withdrawn from the pleural cavity by needle aspiration and tested as listed in the previous and following tables.

LDH = lactate dehydrogenase; WBC = white blood cell.
INDICATIONS:
• Differentiate transudates from exudates
• Evaluate effusion of unknown cause
• Investigate suspected rupture, immune disease, malignancy, or infection

RESULT:
• *Bacterial or tuberculous empyema:* Red blood cell (RBC) count less than 5000/mm³, white blood cell (WBC) count 25,000 to 100,000/mm³ with a predominance of neutrophils, increased fluid protein–to–serum protein ratio, increased fluid LDH–to–serum LDH ratio, decreased glucose, pH less than 7.3.
• *Chylos pleural effusion:* Marked increase in both triglycerides (two to three times serum level) and chylomicrons.
• *Effusion caused by pneumonia:* RBC count less than 5000/mm³, WBC count 5000 to 25,000/mm³ with a predominance of neutrophils and some eosinophils, increased fluid protein–to–serum protein ratio, increased fluid LDH–to–serum LDH ratio, pH less than 7.4 (and decreased glucose if bacterial pneumonia).
• *Esophageal rupture:* Significantly decreased pH (6.0) and elevated amylase.
• *Hemothorax:* Bloody appearance, increased RBC count, elevated hematocrit.
• *Malignancy:* RBC count 1000 to 100,000/mm³, WBC count 5000 to 10,000/mm³ with a predominance of lymphocytes, abnormal cytology, increased fluid protein–to–serum protein ratio, increased fluid LDH–to–serum LDH ratio, decreased glucose, pH less than 7.3.
• *Pancreatitis:* RBC count 1000 to 10,000/mm³, WBC count 5000 to 20,000/mm³ with a predominance of neutrophils, pH greater than 7.3, increased fluid protein–to–serum protein ratio, increased fluid LDH–to–serum LDH ratio, increased amylase.
• *Pulmonary infarction:* RBC count 10,000 to 100,000/mm³, WBC count 5000 to 15,000/mm³ with a predominance of neutrophils, pH greater than 7.3, normal glucose, increased fluid protein–to–serum protein ratio, and increased fluid LDH–to–serum LDH ratio.
• *Pulmonary tuberculosis:* RBC count 10,000/mm³, WBC count 5000 to 10,000/mm³ with a predominance of lymphocytes, positive acid-fast bacillus stain and culture, increased protein, decreased glucose, pH less than 7.3.
• *Rheumatoid disease:* Normal RBC count, WBC count 1000 to 20,000/mm³ with a predominance of either lymphocytes or neutrophils, pH less than 7.3, decreased glucose, increased fluid protein–to–serum protein ratio, increased fluid LDH–to–serum LDH ratio, increased immunoglobulins.
• *Systemic lupus erythematosus:* Similar findings as with rheumatoid disease, except that glucose is usually not decreased.

CRITICAL VALUES: Note and immediately report to the health care provider (HCP) positive culture results, if ordered, and related symptoms. pH 7.1–7.2 indicates need for immediate drainage.

INTERFERING FACTORS:
• Bloody fluids may be the result of a traumatic tap.
• Unknown hyperglycemia or hypoglycemia may be misleading in the comparison of fluid and serum glucose levels. Therefore, it is advisable to collect comparative serum samples a few hr before performing thoracentesis.
NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is primarily used to classify the type of effusion being produced and identify the cause of its accumulation.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune and reproductive systems, especially any bleeding disorders and other symptoms, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Discuss with the patient that the requesting HCP may request that a cough suppressant be given before the thoracentesis.
- Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to needle insertion through the chest wall into the pleural space. Explain that any discomfort with the needle insertion will be minimized with local anesthetics and systemic analgesics. Explain that the local anesthetic injection may cause an initial stinging sensation. Meperidine (Demerol) or morphine may be given as a sedative. Inform the patient that the needle insertion is performed under sterile conditions by a HCP specializing in this procedure. The procedure usually takes about 20 min to complete.
- Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food or fluid restrictions, unless by medical direction. The requesting HCP may request that anticoagulants and aspirin be withheld. The number of days to withhold medication is dependent on the type of anticoagulant.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:
- Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Notify the HCP if patient anticoagulant therapy has not been withheld.
- Have emergency equipment readily available. Keep resuscitation equipment on hand in the case of respiratory impairment or laryngospasm after the procedure.
- Avoid using morphine sulfate in those with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.
- Have the patient remove clothing and change into a gown for the procedure. Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location.
- Record baseline vital signs and continue to monitor throughout the procedure. Protocols may vary from facility to facility.

Access additional resources at davisplus.fadavis.com
Evaluate the patient for symptoms indicating the development of pneumothorax, such as dyspnea, tachypnea, anxiety, decreased breathing sounds, or restlessness. Prepare the patient for a chest x-ray, if ordered, to ensure that a pneumothorax has not occurred as a result of the procedure.

Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.

Administer antibiotics, as ordered, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.

Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, if appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**POST-TEST:**

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual medications, as directed by the HCP.

Monitor vital signs every 15 min for the first hr, every 30 min for the next 2 hr, every hour for the next 4 hr, and every 4 hr for the next 24 hr. Take the patient’s temperature every 4 hr for 24 hr. Monitor intake and output for 24 hr. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

Observe the patient for signs of respiratory distress or skin color changes.

Observe the thoracentesis site for bleeding, inflammation, or hematoma formation each time vital signs are taken and daily thereafter for several days.

Observe the patient for hemoptysis, difficulty breathing, cough, air hunger, pain, or absent breathing sounds over the affected area. Report to HCP.

Inform the patient that 1 hr or more of bed rest (lying on the unaffected side) is required after the procedure. Elevate the patient’s head for comfort.

**RELATED MONOGRAPHS:**

Related tests include antibodies anti-cyclic citrullinated peptide, ANA, biopsy lung, blood gases, CEA and cancer antigens, chest x-ray, complete blood count, WBC count and differential, CT thoracic, CRP, culture and smear mycobacteria, culture blood, culture fungal, culture viral, ECG, ESR, MRI chest, and RF.

Refer to the Immune and Reproductive System tables at the back of the book for related tests by body system.
SYNONYM/ACRONYM: Coproporphyrin, porphobilinogen, urobilinogen, and other porphyrins.

SPECIMEN: Urine (10 mL) from a random or timed specimen collected in a clean, amber-colored plastic collection container with sodium carbonate as a preservative.

REFERENCE VALUE: (Method: Chromatography for uroporphyrins; spectrophotometry for δ-aminolevulinic acid, urobilinogen, and porphobilinogen)

DESCRIPTION: Porphyrins are produced during the synthesis of heme. If heme synthesis is disturbed, these precursors accumulate and are excreted in the urine in excessive amounts.

Access additional resources at davisplus.fadavis.com
Conditions producing increased levels of heme precursors are called porphyrias. The two main categories of genetically determined porphyrias are erythropoietic porphyrias, in which major abnormalities occur in red blood cell chemistry, and hepatic porphyrias, in which heme precursors are found in urine and feces. Erythropoietic and hepatic porphyrias are rare. Acquired porphyrias are characterized by greater accumulation of precursors in urine and feces than in red blood cells. Lead poisoning is the most common cause of acquired porphyrias. Porphyrins are reddish fluorescent compounds. Depending on the type of porphyrin present, the urine may be reddish, resembling port wine. Porphobilinogen is excreted as a colorless compound. A color change may occur in an acidic sample containing porphobilinogen if the sample is exposed to air for several hours.

**INDICATIONS:**
- Assist in the diagnosis of congenital or acquired porphyrias, characterized by abdominal pain, tachycardia, emesis, fever, leukocytosis, and neurologic abnormalities
- Detect suspected lead poisoning, as indicated by elevated porphyrins

**RESULT:**
*Increased in:*
- Acute hepatic porphyrias
- Congenital or acquired porphyrias
- Heavy metal, benzene, or carbon tetrachloride toxicity
- Variegated porphyrias

*Decreased in:* N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase urine porphyrin levels include acriflavine, aminopyrine, ethoxazene, griseofulvin, hexachlorobenzene, oxytetracycline, and sulfonmethane.
- Numerous drugs are suspected as potential initiators of acute attacks, but drugs classified as unsafe for high-risk individuals include aminopyrine, aminoglutethimide, antipyrine, barbiturates, N-butylscopolammonium bromide, carbamazepine, carbolmal, chlorpropamide, danazol, dapsone, diclofenac, diphenhydantoin, ergot preparations, ethchlorvynol, ethinamate, glutethimide, griseofulvin, N-isopropyl meprobamate, mephenytin, meprobamate, methyprylon, novobiocin, phenylbutazone, primidone, pyrazolone preparations, succinimides, sulfonamide antibiotics, sulfonemethylmethylene, sulfonmethane, synthetic estrogens and progestins, tolazamide, tolbutamide, trimethadione, and valproic acid.
- Exposure of the specimen to light can falsely decrease values.
- Screening methods are not well standardized and can produce false-negative results.
- Failure to collect all urine and store specimen properly during the 24-hour test period will interfere with results.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate porphyrias.
- Obtain a history of the patient's complaints, including a list of known allergens especially allergies or sensitivities to latex.
Obtain a history of the patient’s hematopoietic system, symptoms and results of previously performed laboratory tests, diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.

Usually a 24-hour time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hour period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.

Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

If the patient has a history of an allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection.

**Random Specimen (Collect in Early Morning):**

**Clean-Catch Specimen:**

Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.

Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

**Indwelling Catheter:**

Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 minutes before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

**Timed Specimen:**

Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.

Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.

If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.

At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
Include on the collection container’s label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.

**General:**
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

**RELATED MONOGRAPHS:**
- Related tests include δ-aminolevulinic acid, erythrocyte protoporphyrin, and lead.
- Refer to the Hematopoietic System table at the back of the book for related tests by body system.

---

**Positron Emission Tomography, Brain**

**SYNONYM/ACRONYM:** PET scan of the brain.

**AREA OF APPLICATION:** Brain.

**CONTRAST:** IV radioactive material (fluorodeoxyglucose [FDG]).

**DESCRIPTION:** Positron emission tomography (PET) combines the biochemical properties of nuclear medicine with the accuracy of computed tomography (CT). PET uses positron emissions from specific radionuclides (oxygen, nitrogen, carbon, and fluorine) to produce detailed functional images within the body. After the radionuclide becomes concentrated in the brain, PET images of blood flow or metabolic processes at the cellular level can be obtained. Fluorine-18, in the form of fluorodeoxyglucose (FDG), is one of the more commonly used radionuclides. FDG is a glucose analogue, and because every cell uses glucose, the metabolic activity occurring in neurological conditions can be measured. There is little localization of FDG in normal tissue, allowing rapid detection of abnormal disease states. The brain uses oxygen and glucose almost exclusively to meet its energy needs, and therefore the brain’s metabolism has been studied widely with PET.
The positron radiopharmaceuticals generally have short half-lives, ranging from a few seconds to a few hours, and therefore they must be produced in a cyclotron located near where the test is being done. The PET scanner translates the emissions from the radioactivity as the positron combines with the negative electrons from the tissues and forms gamma rays that can be detected by the scanner. This information is transmitted to the computer, which determines the location and its distribution and translates the emissions as color-coded images for viewing, quantitative measurements, activity changes in relation to time, and three-dimensional computer-aided analysis. Each radionuclide tracer is designed to measure a specific body process, such as glucose metabolism, blood flow, or brain tissue perfusion. The radionuclide can be administered IV or inhaled as a gas. PET has had the greatest clinical impact in patients with epilepsy, dementia, neurodegenerative diseases, inflammation, cerebrovascular disease (indirectly), and brain tumors.

The expense of the study and the limited availability of radiopharmaceuticals limit the use of PET, even though it is more sensitive than traditional nuclear scanning and single-photon emission computed tomography. Changes in reimbursement and the advent of mobile technology have increased the availability of this procedure in the community setting.

**INDICATIONS:**
- Detect Parkinson’s disease and Huntington’s disease, as evidenced by decreased metabolism
- Determine the effectiveness of therapy, as evidenced by biochemical activity of normal and abnormal tissues
- Determine physiological changes in psychosis and schizophrenia
- Differentiate between tumor recurrence and radiation necrosis
- Evaluate Alzheimer’s disease and differentiate it from other causes of dementia, as evidenced by decreased cerebral flow and metabolism
- Evaluate cranial tumors pre- and postoperatively and determine stage and appropriate treatment or procedure
- Identify cerebrovascular accident or aneurysm, as evidenced by decreased blood flow and oxygen use
- Identify focal seizures, as evidenced by decreased metabolism between seizures

**RESULT:**

**Normal findings in:**
- Normal patterns of tissue metabolism, blood flow, and radionuclide distribution

**Abnormal findings in:**
- Alzheimer’s disease
- Aneurysm
- Cerebral metastases
- Cerebrovascular accident
- Creutzfeldt-Jakob disease
- Dementia
- Head trauma
- Huntington’s disease
- Migraine
- Parkinson’s disease
- Schizophrenia
- Seizure disorders
- Tumors

**CRITICAL VALUES:**
- Aneurysm
- CVA
- Tumor with significant mass effect

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.
**INTERFERING FACTORS:**

*This procedure is contraindicated for:*

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

*Factors that may impair clear imaging:*

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Drugs that alter glucose metabolism, such as tranquilizers or insulin, because hypoglycemia can alter PET results
- The use of alcohol, tobacco, or caffeine-containing drinks at least 24 hr before the study, because the effects of these substances would make it difficult to evaluate the patient’s true physiological state (e.g., alcohol is a vasconstrictor and would decrease blood flow to the target organ)
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

*Other considerations:*

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- False-positive findings may occur as a result of normal gastrointestinal tract uptake and uptake in areas of infection or inflammation.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

---

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses blood flow to the brain and brain tissue metabolism.
- Obtain a history of the patient’s complaints including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, or anesthetics.
- Obtain a history of the patient’s musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that radioactive material poses minimal radioactive hazard because of its short half-life and rarely produces side effects. Inform the patient that the procedure is performed in a special department, usually in a radiology suite, by a HCP specializing in this
procedure, with support staff, and takes approximately 60 to 120 min.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. Sometimes FDG examinations are done after blood has been drawn to determine circulating blood glucose levels. If blood glucose levels are high, insulin may be given.

Instruct the patient to perform different cognitive activities (e.g., reading) to measure changes in brain activity during reasoning or remembering.

The patient may be asked to perform different cognitive activities (e.g., reading) to measure changes in brain activity during reasoning or remembering.

The patient may be blindfolded or asked to use earplugs to decrease auditory and visual stimuli.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume pretest diet, fluids, medications, or activity.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.

Instruct the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body, unless contraindicated. Educate the patient that radionuclide is eliminated from the body within 6 to 24 hr.

Instruct the patient to flush the toilet immediately after each voiding, and to meticulously wash hands with soap and water for 24 hr after the procedure.

Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.

If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated, about 3 days. Instruct her to express the milk and discard it during the 3-day period to prevent cessation of milk production.

**INTRATEST:**

Ensure that the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations.

Ensure the patient has removed all jewelry and external metallic objects from the area to be examined prior to the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Record baseline vital signs and assess neurological status. Protocols may vary from facility to facility.

Place the patient in the supine position on an exam table.

The radionuclide is injected, and imaging is started after a 30-min delay. If comparative studies are indicated, additional injections may be needed.

The patient may be asked to perform different cognitive activities (e.g., reading) to measure changes in brain activity during reasoning or remembering.

The patient may be blindfolded or asked to use earplugs to decrease auditory and visual stimuli.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
Nutritional considerations: A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.

No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.

Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

Related Monographs:

Related tests include Alzheimer disease markers, CT brain, EEG, MRI brain, and US arterial Doppler of the carotids.

Refer to the Musculoskeletal System table in the back of the book for related tests by body system.

Positron Emission Tomography, Heart

SYNONYM/ACRONYM: PET scan of the heart.

AREA OF APPLICATION: Heart, chest/thorax, vascular system.

CONTRAST: IV radioactive material (fluorodeoxyglucose [FDG]).

DESCRIPTION: Positron emission tomography (PET) combines the biochemical properties of nuclear medicine with the accuracy of computed tomography (CT). PET uses positron emissions from specific radionuclides (oxygen, nitrogen, carbon, and fluorine) to produce detailed functional images within the body. After the radionuclide becomes concentrated in the heart, PET images of blood flow or metabolic processes at the cellular level can be obtained. Fluorine-18, in the form of fluorodeoxyglucose (FDG), is one of the more commonly used radionuclides. FDG is a glucose analogue, and because every cell uses glucose, the metabolic activity occurring in heart conditions such as myocardial viability can be measured. There is little localization of FDG in normal tissue, allowing rapid detection of abnormal disease states.

The positron radiopharmaceuticals generally have short half-lives, ranging from a few seconds to a few hours, and therefore they must be produced in a cyclotron located near where the test is being done. The PET scanner translates the emissions from the radioactivity as the positron combines with the negative electrons from the tissues and forms gamma rays that can be detected by the scanner. This information is transmitted to
the computer, which determines the location and its distribution and translates the emissions as color-coded images for viewing, quantitative measurements, activity changes in relation to time, and three-dimensional computer-aided analysis. Each radionuclide tracer is designed to measure a specific body process, such as glucose metabolism, blood flow, or tissue perfusion. The radionuclide can be administered IV or inhaled as a gas.

The expense of the study and the limited availability of radiopharmaceuticals limit the use of PET, even though it is more sensitive than traditional nuclear scanning and single-photon emission computed tomography. Changes in reimbursement and the advent of mobile technology have increased the availability of this procedure in the community setting.

**INDICATIONS:**
- Assess tissue permeability
- Determine the effects of therapeutic drugs on malfunctioning or diseased tissue
- Determine localization of areas of heart metabolism
- Determine the presence of coronary artery disease (CAD), as evidenced by metabolic state during ischemia and after angina
- Determine the size of heart infarcts
- Identify cerebrovascular accident or aneurysm, as evidenced by decreasing blood flow and oxygen use

**RESULT:**

**Normal findings in:**
- Normal patterns of tissue metabolism, blood flow, and radionuclide distribution

**Abnormal findings in:**
- Chronic obstructive pulmonary disease
- Decreased blood flow and decreased glucose concentration, indicating necrotic, scarred tissue
- Enlarged left ventricle
- Heart chamber disorder
- Myocardial infarction, indicating increased radionuclide uptake in the myocardium
- Pulmonary edema
- Reduced blood flow but increased glucose concentration, indicating ischemia

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

This procedure is contraindicated for:
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Drugs that alter glucose metabolism, such as tranquilizers or insulin, because hypoglycemia can alter PET results
- The use of alcohol, tobacco, or caffeine-containing drinks at least 24 hr before the study, because the effects of these substances would make it difficult to evaluate the patient’s true physiological state (e.g., alcohol is a vasconstrictor and would decrease blood flow to the target organ)
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

**Other considerations:**
- Failure to follow dietary restrictions before the procedure may
cause the procedure to be canceled or repeated.

- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.

- False-positive findings may occur as a result of normal gastrointestinal tract uptake and uptake in areas of infection or inflammation.

- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- Inform the patient that the procedure assesses blood flow to the heart.

- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, or anesthetics.

- Obtain a history of the patient’s cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.

- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals.

- Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that radioactive material poses minimal radioactive hazard because of its short half-life and rarely produces side effects. - **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- Sometimes FDG examinations are done after blood has been drawn to determine circulating blood glucose levels. If blood glucose levels are high, insulin may be given.

- Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.

- Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.

- Instruct the patient to restrict food for 4 hr; restrict alcohol, nicotine, or caffeine-containing drinks for 24 hr; and withhold medications for 24 hr before the test. Protocols may vary from facility to facility.

- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure that the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations.

- Ensure the patient has removed all jewelry and external metallic objects from the area to be examined prior to the procedure.

- Have emergency equipment readily available.
Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Record baseline vital signs and assess neurological status. Protocols may vary from facility to facility.

Place the patient in the supine position on an exam table.

The radionuclide is injected and imaging is done at periodic intervals, with continuous scanning done for 1 hr. If comparative studies are indicated, additional injections may be needed.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

POST-TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume pretest diet, fluids, medications, and activity.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.

Instruct the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body, unless contraindicated. Educate the patient that radionuclide is eliminated from the body within 6 to 24 hr.

Instruct the patient to flush the toilet immediately after each voiding, and to meticulously wash hands with soap and water for 24 hr after the procedure.

Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.

If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated, about 3 days. Instruct her to express the milk and discard it during the 3-day period to prevent cessation of milk production.

**Nutritional considerations:** A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and CAD.

No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.

**Positron Emission Tomography, Pelvis**

**SYNONYM/ACRONYM:** PET scan of the pelvis.

**AREA OF APPLICATION:** Pelvis.

**CONTRAST:** IV radioactive material (fluorodeoxyglucose [FDG]).

**DESCRIPTION:** Positron emission tomography (PET) combines the biochemical properties of nuclear medicine with the accuracy of computed tomography (CT). PET uses positron emissions from specific radionuclides (oxygen, nitrogen, carbon, and fluorine) to produce detailed functional images within the body. After the radionuclide becomes concentrated in the pelvis, PET images of blood flow or metabolic processes at the cellular level can be obtained. Colorectal tumor detection, tumor staging, evaluation of the effects of therapy, detection of recurrent disease, and detection of metastases are the main reasons to do a pelvic PET scan. Fluorine-18, in the form of fluorodeoxyglucose (FDG), is one of the more commonly used radionuclides. FDG is a glucose analogue, and because every cell uses glucose, the metabolic activity occurring in pelvic conditions such as colorectal cancer can be measured. There is little localization of FDG in normal tissue, allowing rapid detection of abnormal disease states.

The positron radiopharmaceuticals generally have short half-lives, ranging from a few seconds to a few hours, and therefore they must be produced in a cyclotron located near where the test is being done. The PET scanner translates the emissions from the radioactivity as the positron combines with the negative electrons from the
**INDICATIONS:**

- Determine the effects of therapy
- Determine the presence of colorectal cancer
- Determine the presence of metastases of a cancerous tumor
- Determine the recurrence of tumor or cancer
- Identify the site for biopsy

**RESULT:**

**Normal findings in:**

- Normal patterns of tissue metabolism, blood flow, and radionuclide distribution
- No focal uptake of radionuclide

**Abnormal findings in:**

- Focal uptake of the radionuclide in pelvis
- Focal uptake in abnormal lymph nodes

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

*This procedure is contraindicated for:*

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

*Factors that may impair clear imaging:*

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Drugs that alter glucose metabolism, such as tranquilizers or insulin, because hypoglycemia can alter PET results
- The use of alcohol, tobacco, or caffeine-containing drinks at least 24 hr before the study, because the effects of these substances would make it difficult to evaluate the patient’s true physiological state (e.g., alcohol is a vasconstrictor and would decrease blood flow to the target organ)
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images

*Other considerations:*

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- False-positive findings may occur as a result of normal gastrointestinal (GI) tract uptake and uptake in areas of infection or inflammation.

Access additional resources at davisplus.fadavis.com
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses the pelvis and its contents for abnormal organ function.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, or anesthetics.
• Obtain a history of the patient’s GI system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
• Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Reassure the patient that radioactive material poses minimal radioactive hazard because of its short half-life and rarely produces side effects. Inform the patient that the procedure is performed in a special department, usually in a radiology suite, by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
• Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• Sometimes FDG examinations are done after blood has been drawn to determine circulating blood glucose levels. If blood glucose levels are high, insulin may be given.
• Instruct the patient to remove jewelry and other metallic objects in the area to be examined.
• Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.
• Instruct the patient to restrict food for 4 hr; restrict alcohol, nicotine, or caffeine-containing drinks for 24 hr; and withhold medications for 24 hr before the test. Protocols may vary from facility to facility.
• Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:
• Ensure that the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations.
• Ensure the patient has removed all jewelry and external metallic objects from the area to be examined prior to the procedure.
• Have emergency equipment readily available.
• Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
• Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
• Observe standard precautions, and follow the general guidelines in Appendix A.
• Record baseline vital signs and assess neurological status. Protocols may vary from facility to facility.
Place the patient in the supine position on an exam table.

The radionuclide is injected, and imaging is started after a 45-min delay. Continuous scanning may be done for 1 hr. If comparative studies are indicated, additional injections of radionuclide may be needed.

If required, the bladder may need to be lavaged via a urinary catheter with 2 L of 0.9% saline solution to remove concentrated radionuclide.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume pretest diet, fluids, medications, and activity.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- Instruct the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- Instruct the patient to flush the toilet immediately after each voiding, and to meticulously wash hands with soap and water for 24 hr after the procedure.

Tell all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.

If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated, about 3 days. Instruct her to express the milk and discard it during the 3-day period to prevent cessation of milk production.

No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.

Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include barium enema, biopsy intestinal, capsule endoscopy, cancer antigens, CT abdomen, fecal analysis, KUB, CT colonoscopy, MRI abdomen, and proctosigmoidoscopy.
- Refer to the Gastrointestinal System table in the back of the book for related tests by body system.

*Note: Serum values are 0.1 mmol/L higher than plasma values, and reference ranges should be adjusted accordingly. It is important that serial measurements be collected using the same type of collection container to reduce variability of results from collection to collection.*

**DESCRIPTION:** Electrolytes dissociate into electrically charged ions when dissolved. Cations, including potassium, carry a positive charge. Body fluids contain approximately equal numbers of anions and cations, although the nature of the ions and their mobility differs between the intracellular and extracellular compartments. Both types of ions affect the electrical and osmolar functions of the body. Electrolyte quantities and the balance among them are controlled by oxygen and carbon dioxide exchange in the lungs; absorption, secretion, and excretion of many substances by the kidneys; and secretion of regulatory hormones by the endocrine glands. Potassium is the most abundant intracellular cation. It is essential for the transmission of electrical impulses in cardiac and skeletal muscle. It also functions in enzyme reactions that transform glucose into energy and amino acids into proteins. Potassium helps maintain acid-base equilibrium, and it has a significant and inverse relationship to pH: A decrease in pH of 0.1 increases the potassium level by 0.6 mEq/L.

Abnormal potassium levels can be caused by a number of contributing factors, which can be categorized as follows:

*Altered renal excretion:* Normally, 80% to 90% of the body's potassium is filtered out through the kidneys each day (the remainder is excreted in sweat and stool); renal disease can result in abnormally high potassium levels.

*Altered dietary intake:* A severe potassium deficiency can be caused by an inadequate intake of dietary potassium.

*Altered cellular metabolism:* Damaged red blood cells (RBCs) release potassium into the circulating fluid, resulting in increased potassium levels.

**INDICATIONS:**
- Assess a known or suspected disorder associated with renal disease, glucose metabolism, trauma, or burns
• Assist in the evaluation of electrolyte imbalances; this test is especially indicated in elderly patients, patients receiving hyperalimentation supplements, patients on hemodialysis, and patients with hypertension
• Evaluate cardiac arrhythmia to determine whether altered potassium levels are contributing to the problem, especially during digitalis therapy, which leads to ventricular irritability
• Evaluate the effects of drug therapy, especially diuretics
• Evaluate the response to treatment for abnormal potassium levels
• Monitor known or suspected acidosis, because potassium moves from RBCs into the extracellular fluid in acidotic states
• Routine screen of electrolytes in acute and chronic illness

RESULT:

**Increased in:**
- Acidosis *Intracellular potassium ions are expelled in exchange for hydrogen ions in order to achieve electrical neutrality*
- Acute renal failure *Potassium excretion is diminished and it accumulates in the blood*
- Addison’s disease *Due to lack of aldosterone, potassium excretion is diminished and it accumulates in the blood*
- Asthma *Related to chronic inflammation and damage to lung tissue*
- Burns *Related to tissue damage and release by damaged cells*
- Chronic interstitial nephritis *Potassium excretion is diminished and it accumulates in the blood*
- Dehydration *Hemoconcentration*
- Dialysis *Dialysis treatments simulate kidney function but potassium builds up between treatments*
- Diet *Related to excessive intake of salt substitutes or of potassium salts in medications*
- Exercise *Related to tissue damage and release by damaged cells*
- Hemolysis (massive) *Potassium is the major intracellular cation*
- Hyperventilation *Response to respiratory alkalosis is increased blood levels of potassium in order to achieve electrical neutrality*
- Hypoaldosteronism *Due to lack of aldosterone, potassium excretion is diminished and it accumulates in the blood*
- Insulin deficiency *Insulin deficiency results in movement of potassium from the cell into the extracellular fluid*
- Ketoacidosis *Insulin deficiency results in movement of potassium from the cell into the extracellular fluid*
- Leukocytosis
- Muscle necrosis *Related to tissue damage and release by damaged cells*
- Near drowning
- Pregnancy
- Prolonged periods of standing
- Tissue trauma *Release by damaged cells*
- Transfusion of old banked blood *Aged cells hemolyze and release intracellular potassium*
- Tubular unresponsiveness to aldosterone
- Uremia

**Decreased in:**
- Alcoholism *Related to insufficient dietary intake*
- Alkalosis *Potassium uptake by cells is increased in response to release of hydrogen ions from cells*
- Anorexia nervosa *Related to significant changes in renal function that result in hypokalemia*
- Bradycardia *Hypokalemia can cause bradycardia*
• Chronic, excessive licorice ingestion (from licorice root)
• Congestive heart failure (Related to fluid retention and hemodilution)
• Crohn’s disease (Insufficient intestinal absorption)
• Cushing’s syndrome (Aldosterone facilitates the excretion of potassium by the kidneys)
• Diet deficient in meat and vegetables (Insufficient dietary intake)
• Excess insulin (Insulin causes glucose and potassium to move into cells)
• Familial periodic paralysis (Related to fluid retention)
• Gastrointestinal (GI) loss due to vomiting, diarrhea, nasogastric suction, or intestinal fistula
• Hyperaldosteronism (Aldosterone facilitates the excretion of potassium by the kidneys)
• Hypertension (Medications used to treat hypertension may result in loss of potassium; hypertension is often related to diabetes and renal disease which affect cellular retention and renal excretion of potassium respectively)
• Hypomagnesemia (Magnesium levels tend to parallel potassium levels)
• IV therapy with inadequate potassium supplementation
• Laxative abuse (Medications cause potassium wasting)
• Malabsorption (Insufficient intestinal absorption)
• Pica (eating substances of no nutritional value, e.g., clay)
• Renal tubular acidosis (Condition results in excessive loss of potassium)
• Sweating (Increased loss)
• Theophylline administration, excessive (Theophylline drives potassium into cells, reducing circulating levels)
• Thyrotoxicosis (Related to changes in renal function)

CRITICAL VALUES:
• Less than 2.5 mmol/L
• Greater than 6.5 mmol/L

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms, especially symptoms of fluid imbalance.

Symptoms of hyperkalemia include irritability, diarrhea, cramps, oliguria, difficulty speaking, and cardiac arrhythmias (peaked T waves and ventricular fibrillation). Continuous cardiac monitoring is indicated. Administration of sodium bicarbonate or calcium chloride may be requested. If the patient is receiving an IV supplement, verify that the patient is voiding.

Symptoms of hypokalemia include malaise, thirst, polyuria, anorexia, weak pulse, low blood pressure, vomiting, decreased reflexes, and electrocardiographic changes (depressed T waves and ventricular ectopy). Replacement therapy is indicated.

INTERFERING FACTORS:
• Drugs that can cause an increase in potassium levels include dexamethasone, enalapril, mannitol, methicillin, metoprolol, NSAIDs, some drugs with potassium salts, propranolol, spironolactone, and succinylcholine.
• Drugs that can cause a decrease in potassium levels include acetazolamide, acetylsalicylic acid, alanine, albuterol, aldosterone, ammonium chloride, amphotericin B, bicarbonate, bisacodyl, captopril, carbencillin, cathartics, cisplatin, clorexolone, desoxycorticosterone, dexamethasone, digoxin, diuretics, enalapril, furosemide, hydrocortisone, hydroflumethiazide, laxatives, moxalactam (common
when coadministered with amikacin), large doses of any IV penicillin, phenolphthalein (with chronic laxative abuse), phosphates, IV theophylline, thiazides, and triamterene. A number of these medications initially increase the serum potassium level, but they also have a diuretic effect, which promotes potassium loss in the urine except in cases of renal insufficiency.

- Leukocytosis, as seen in leukemia, causes elevated potassium levels.
- False elevations can occur with vigorous pumping of the hand during venipuncture. Hemolysis of the sample and high platelet counts also increase potassium levels, as follows: (1) Because potassium is an intracellular ion and concentrations are approximately 150 times extracellular concentrations, even a slight amount of hemolysis can cause a significant increase in levels. (2) Platelets release potassium during the clotting process, and therefore serum samples collected from patients with elevated platelet counts may produce spuriously high potassium levels. Plasma would be the specimen of choice in patients known to have elevated platelet counts.
- False increases are seen in unprocessed samples left at room temperature because a significant amount of potassium leaks out of the cells within a few hr. Plasma or serum should be separated from cells within 4 hr of collection.
- Storage of unprocessed blood causes potassium levels to increase because a significant amount of potassium leaks out of the cells within a few hr. Plasma or serum should be separated from cells within 4 hr of collection.
- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is present in the IV solution, falsely increasing the result.

**Nursing Implications and Procedure**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess electrolyte balance.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex. Especially note complaints of weakness and confusion.
- Obtain a history of the patient’s cardiovascular, endocrine, GI, genitourinary, immune, and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement. Instruct patient not to clench and unclench the fist immediately before or during specimen collection.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label
the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

**Nutritional considerations:** There are no recommended dietary allowances established for potassium, but the estimated minimum intake for adults is 200 mEq/d. Potassium is present in all plant and animal cells, making dietary replacement simple to achieve in the potassium-deficient patient.

- Observe the patient for signs and symptoms of fluid volume excess related to excess potassium intake, fluid volume deficit related to active loss, or risk of injury related to an alteration in body chemistry. Symptoms include dehydration, diarrhea, vomiting, or prolonged anorexia. Instruct the patient in electrolyte replacement therapy and changes in dietary intake that affect electrolyte levels.

- Increased potassium levels may be associated with dehydration. Evaluate the patient for signs and symptoms of dehydration. Dehydration is a significant and common finding in geriatric patients and other patients in whom renal function has deteriorated.

**RELATED MONOGRAPHS:**

- Related tests include ACTH, aldosterone, anion gap, antiarrhythmic drugs, alveolar/arterial gradient, ANP, BNP, blood gases, BUN, calcium, carbon dioxide, chloride, complement, complete blood count, hematocrit, complete blood count, hemoglobin, complete blood count, WBC count and differential, Coomb’s antiglobulin (direct and indirect), cortisol, CK and isoenzymes, creatinine, DHEAS, echocardiography, echocardiography transesophageal, fecal fat, glucose, G6PD, Ham’s test, haptoglobin, hemosiderin, insulin, ketones, lactic acid, lung perfusion scan, magnesium, osmolality, osmotic fragility, plethysmography, urine potassium, PFT, PK, renin, sickle cell screen, and sodium.

- Refer to the Cardiovascular, Endocrine, Gastrointestinal, Genitourinary, Immune, and Respiratory System tables at the back of the book for related tests by body system.

---

**Potassium, Urine**

**SYNONYM/ACRONYM:** Urine K⁺.

**SPECIMEN:** Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

**REFERENCE VALUE:** (Method: Ion-selective electrode).
Electrolytes dissociate into electrically charged ions when dissolved. Cations, including potassium, carry a positive charge. Body fluids contain approximately equal numbers of anions and cations, although the nature of the ions and their mobility differs between the intracellular and extracellular compartments. Both types of ions affect the electrical and osmolar functions of the body. Electrolyte quantities and the balance among them are controlled by oxygen and carbon dioxide exchange in the lungs; absorption, secretion, and excretion of many substances by the kidneys; and secretion of regulatory hormones by the endocrine glands. Potassium is the most abundant intracellular cation. It is essential for the transmission of electrical impulses in cardiac and skeletal muscle. It also functions in enzyme reactions that transform glucose into energy and amino acids into proteins. Potassium helps maintain acid-base equilibrium, and it has a significant and inverse relationship to pH: A decrease in pH of 0.1 increases the potassium level by 0.6 mEq/L.

Abnormal potassium levels can be caused by a number of contributing factors, which can be categorized as follows:

**Altered renal excretion:** Normally, 80% to 90% of the body’s potassium is filtered out through the kidneys each day (the remainder is excreted in sweat and stool); renal disease can result in abnormally high potassium levels.

**Altered dietary intake:** A severe potassium deficiency can be caused by an inadequate intake of dietary potassium.

**Altered cellular metabolism:** Damaged red blood cells (RBCs) release potassium into the circulating fluid, resulting in increased potassium levels.

Regulating electrolyte balance is one of the major functions of the kidneys. In normally functioning kidneys, urine potassium levels increase when serum levels are high and decrease when serum levels are low to maintain homeostasis. The kidneys respond to alkalosis by excreting potassium to retain hydrogen ions and increase acidity. In acidosis, the body excretes hydrogen ions and retains potassium. Analyzing these urinary levels can provide important clues to the functioning of the kidneys and other major organs. Urine potassium tests usually involve timed urine collections over a 12- or 24-hr period. Measurement of random specimens also may be requested.

*Note:* Reference values depend on potassium intake and diurnal variation. Excretion is significantly higher at night.
INDICATIONS:
• Determine the potential cause of renal calculi
• Evaluate known or suspected endocrine disorder
• Evaluate known or suspected renal disease
• Evaluate malabsorption disorders

RESULT:
Increased in:
• Albright-type renal disease (Related to excessive production of cortisol)
• Cushing’s syndrome (Excessive corticosteroids, especially aldosterone levels will increase urinary excretion of potassium)
• Diabetic ketoacidosis (Deficiency of insulin forces potassium into the extracellular fluid; excess potassium is excreted in the urine)
• Diuretic therapy (Related to potassium wasting effects of the medications)
• Hyperaldosteronism (Excessive aldosterone levels will increase urinary excretion of potassium)
• Starvation (onset) (Cells involved in providing energy through tissue breakdown release potassium into circulation)
• Vomiting (Elevated urine potassium is a hallmark of bulimia)

Decreased in:
• Addison’s disease (Reduced aldosterone levels will diminish excretion of potassium by the kidneys)
• Potassium deficiency (chronic)
• Renal failure with decreased urine flow

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs and substances that can cause an increase in urine potassium levels include acetazolamide, acetylsalicylic acid, ammonium chloride, bendroflumethiazide, carbonoxolone, chlorothalidone, citrates, clopamide, corticosteroids, cortisone, desoxycorticosterone, dexamethasone, diuretics, dopamine, ethacrynic acid, glycyr rhiza, intra-amniotic saline, mefruside, niacinamide, some oral contraceptives, thiazides, triflucin, and viomycin.
• Drugs that can cause a decrease in urine potassium levels include alanine, amiloride, anesthetic agents, cyclosporine, felodipine, levarterenol, and ramipril.
• A dietary deficiency or excess of potassium can lead to spurious results.
• Diuretic therapy with excessive loss of electrolytes into the urine may falsely elevate results.
• All urine voided for the timed collection period must be included in the collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.
• Potassium levels are subject to diurnal variation (output being highest at night), which is why 24-hr collections are recommended.

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to evaluate electrolyte balance, acid-base balance, and hypokalemia.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s endocrine, gastrointestinal, and genitourinary systems, symptoms, and
results of previously performed laboratory tests and diagnostic and surgical procedures.

- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.

Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

**Random Specimen (Collect in Early Morning):**

**Clean-Catch Specimen:**

- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

**Indwelling Catheter:**

- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

**Timed Specimen:**

- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
Include on the collection container’s label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.

**General:**
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

**Nutritional considerations:** There are no recommended dietary allowances established for potassium, but the estimated minimum intake for adults is 200 mEq/d. Potassium is present in all plant and animal cells, making dietary replacement simple to achieve in the potassium-deficient patient.
- Observe the patient for signs and symptoms of fluid volume excess related to excess potassium intake, fluid volume deficit related to active loss, or risk of injury related to an alteration in body chemistry. Symptoms include dehydration, diarrhea, vomiting, or prolonged anorexia.
- Instruct the patient in electrolyte replacement therapy and changes in dietary intake that affect electrolyte levels.
- Increased potassium levels may be associated with dehydration. Evaluate the patient for signs and symptoms of dehydration. Dehydration is a significant and common finding in geriatric patients and other patients in whom renal function has deteriorated.

Patients receiving digoxin or diuretics should have potassium levels monitored carefully because cardiac arrhythmias can occur.
- Increased urine potassium levels may be associated with the formation of kidney stones. Educate the patient, if appropriate, on the importance of drinking a sufficient amount of water when kidney stones are suspected.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ACTH, aldosterone, anion gap, BUN, calcium, calculus kidney stone panel, carbon dioxide, chloride, cortisol, creatinine, DHEAS, glucose, insulin, ketones, lactic acid, magnesium, osmolality, phosphorus, potassium, renin, sodium, and UA.
- Refer to the Endocrine, Gastrointestinal, and Genitourinary System tables at the back of the book for related tests by body system.

---

**Prealbumin**

**SYNONYM/ACRONYM:** Transthyretin.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** (Method: Nephelometry)
**DESCRIPTION:** Prealbumin is a protein primarily produced by the liver. It is the major transport protein for triiodothyronine and thyroxine. It is also important in the metabolism of retinol-binding protein, which is needed for transporting vitamin A (retinol). Prealbumin has a short biological half-life of 2 days. This makes it a good indicator of protein status and an excellent marker for malnutrition. Prealbumin is often measured simultaneously with transferrin and albumin.

**INDICATIONS:**
Evaluate nutritional status

**RESULT:**

*Increased in:*
- Alcoholism *(Related to leakage of prealbumin from damaged hepatocytes and/or poor nutrition)*
- Chronic renal failure *(Rapid turnover of prealbumin reflects a perceived elevation in the presence of overall loss of other proteins that take longer to produce)*
- Patients receiving steroids *(These drugs stimulate production of prealbumin)*

*Decreased in:*
- Acute-phase inflammatory response *(Prealbumin is a negative acute phase reactant protein; levels decrease in the presence of inflammation)*
- Diseases of the liver *(Related to decreased ability of the damaged liver to synthesize protein)*
- Hepatic damage *(Related to decreased ability of the damaged liver to synthesize protein)*
- Malnutrition *(Synthesis is decreased due to lack of proper diet)*
- Tissue necrosis *(Prealbumin is a negative acute phase reactant protein; levels decrease in the presence of inflammation)*

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase prealbumin levels include anabolic steroids, anticonvulsants, danazol, oral contraceptives, prednisolone, prednisone, and propranolol.
- Drugs that may decrease prealbumin levels include amiodarone and diethylstilbestrol.
- Fasting 4 hr before specimen collection is highly recommended. Reference ranges are often based on fasting populations to provide some level of standardization for comparison. The presence of lipids in the blood may also interfere with the test method; fasting eliminates this potential source of error, especially if the patient has elevated lipid levels.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

Access additional resources at davisplus.fadavis.com
Inform the patient that the test is used to evaluate nutritional status and assess liver function.
Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
Obtain a history of the patient’s endocrine, gastrointestinal, and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
*Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
Instruct the patient to fast for 4 hr before specimen collection.
There are no fluid or medication restrictions, unless by medical direction.

**INTRATEST:**

- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 4 hr prior to the procedure.
- If the patient has a history of an allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume usual diet, as directed by the HCP.
- *Nutritional considerations:* Nutritional therapy may be indicated for patients with decreased prealbumin levels. Educate the patient, as appropriate, that good dietary sources of complete protein (containing all eight essential amino acids) include meat, fish, eggs, and dairy products; and that good sources of incomplete protein (lacking one or more of the eight essential amino acids) include grains, nuts, legumes, vegetables, and seeds.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include albumin, chloride, ferritin, iron/TIBC, potassium, protein, sodium, T4, T3, transferrin, and vitamin A.
- Refer to the Endocrine, Gastrointestinal, and Hepatobiliary System tables at the back of the book for related tests by body system.
**Proctosigmoidoscopy**

**SYNONYM/ACRONYM:** Anoscopy (anal canal), proctoscopy (rectum), sigmoidoscopy (sigmoid colon), flexible fiberoptic sigmoidoscopy, flexible proctosigmoidoscopy.

**AREA OF APPLICATION:** Anus, rectum, colon.

**CONTRAST:** Air.

**DESCRIPTION:** Proctosigmoidoscopy allows direct visualization of the mucosa of the anal canal (anoscopy), rectum (proctoscopy), and distal sigmoid colon (sigmoidoscopy). The procedure can be performed using a rigid or flexible fiberoptic endoscope, but the flexible instrument is generally preferred. The endoscope is a multichannel device allowing visualization of the mucosal lining of the colon, instillation of air, removal of fluid and foreign objects, obtaining of tissue biopsy specimens, and use of a laser for the destruction of tissue and control of bleeding. The endoscope is advanced approximately 60 cm into the colon. This procedure is commonly used in patients with lower abdominal and perineal pain; changes in bowel habits; rectal prolapse during defecation; or passage of blood, mucus, or pus in the stool. Proctosigmoidoscopy can also be a therapeutic procedure, allowing removal of polyps or hemorrhoids or reduction of a volvulus. Biopsy specimens of suspicious sites may be obtained during the procedure. This procedure is recommended for patients who are more than 50 y.o. as part of a routine screening for colorectal cancer.

**INDICATIONS:**
- Confirm the diagnosis of diverticular disease
- Confirm the diagnosis of Hirschsprung’s disease and colitis in children
- Determine the cause of pain and rectal prolapse during defecation
- Determine the cause of rectal itching, pain, or burning
- Evaluate the cause of blood, pus, or mucus in the stool
- Evaluate postoperative anastomosis of the colon
- Examine the distal colon before barium enema (BE) x-ray to obtain improved visualization of the area, and after a BE when x-ray findings are inconclusive
- Reduce volvulus of the sigmoid colon
- Remove hemorrhoids by laser therapy
- Screen for and excise polyps
- Screen for colon cancer

**RESULT:**

*Normal findings in:* Normal mucosa of the anal canal, rectum, and sigmoid colon

*Abnormal findings in:*
- Anal fissure or fistula
- Anorectal abscess
- Benign lesions
- Bleeding sites
- Bowel infection or inflammation
- Crohn’s disease
- Diverticula
- Hypertrophic anal papillae

Access additional resources at davisplus.fadavis.com
• Internal and external hemorrhoids
• Polyps
• Rectal prolapse
• Tumors
• Ulcerative colitis
• Vascular abnormalities

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with bleeding disorders, especially disorders associated with uremia and cytotoxic chemotherapy
• Patients with cardiac conditions or arrhythmias
• Patients with bowel perforation, acute peritonitis, ischemic bowel necrosis, toxic megacolon, diverticulitis, recent bowel surgery, advanced pregnancy, severe cardiac or pulmonary disease, recent myocardial infarction, known or suspected pulmonary embolus, large abdominal aortic or iliac aneurysm, and coagulation abnormality

Factors that may impair clear imaging:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Strictures or other abnormalities preventing passage of the scope
• Barium swallow or upper gastrointestinal (GI) series within the preceding 48 hr
• Severe lower GI bleeding or the presence of feces, barium, blood, or blood clots

Other considerations:
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
• Use of bowel preparations that include laxatives or enemas should be avoided in pregnant patients or patients with inflammatory bowel disease, unless specifically directed by a health care provider (HCP).

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient the test is primarily used to examine the rectum and the distal portion of the colon.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, and anesthetics.
• Obtain a history of the patient’s GI system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Note any recent procedures that can interfere with test results. Ensure that this procedure is performed before an upper GI study or barium swallow.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
• Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note time and date of last dose.
• Note intake of oral iron preparations within 1 wk before the procedure because these cause black, sticky feces that are difficult to remove with bowel preparation.
• Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to insertion of the anoscope. Inform the patient that the procedure is performed in a GI lab by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
• Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
Instruct the patient that a laxative may be needed the day before the procedure, with cleansing enemas on the morning of the procedure, depending on the institution’s policy.

Inform the patient that the urge to defecate may be experienced when the scope is passed. Encourage slow, deep breathing through the mouth to help alleviate the feeling.

Inform the patient that flatus may be expelled during and after the procedure owing to air that is injected into the scope to improve visualization.

Instruct the patient to eat a low-residue diet for 3 days prior to the procedure. Consume clear liquids only the evening before, and restrict food and fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure that the patient has complied with food, fluid, and medication restrictions and pretesting preparations.
- Administer two small-volume enemas 1 hr before the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and change into the gown, robe, and foot coverings provided.
- Observe standard precautions, and follow the general guidelines in Appendix A. Wear gloves and gown throughout the procedure.
- Record baseline vital signs and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
- Place the patient on an examination table in the left lateral decubitus position or the knee-chest position and drape with the buttocks exposed. The buttocks are placed at or extending slightly beyond the edge of the examination table or bed, preferably on a special examining table that tilts the patient into the desired position.
- The HCP visually inspects the perianal area and then performs a digital rectal examination with a well-lubricated, gloved finger. A fecal specimen may be obtained from the glove when the finger is removed from the rectum.

A lubricated anoscope (7 cm in length) is inserted, and the anal canal is inspected (anoscopy). The anoscope is removed, and a lubricated proctoscope (27 cm in length) or flexible sigmoidoscope (35 to 60 cm in length) is inserted.

The scope is manipulated gently to facilitate passage, and air may be insufflated through the scope to improve visualization. Suction and cotton swabs also are used to remove materials that hinder visualization.

The patient is instructed to take deep breaths to aid in movement of the scope downward through the ascending colon to the cecum and into the terminal portion of the ileum.

Examination is done as the scope is gradually withdrawn. Photographs are obtained for future reference.

At the end of the procedure, the scope is completely withdrawn, and residual lubricant is cleansed from the anal area.

Place fecal or tissue samples and polyps in properly labeled specimen containers, and promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature changes. Protocols may vary from facility to facility.
- Monitor for any rectal bleeding.
- Instruct the patient to resume diet, medication, and activity, as directed by the HCP.
- Instruct the patient to expect slight rectal bleeding for 2 days after removal of polyps or biopsy specimens, but that heavy rectal bleeding must be immediately reported to the HCP.
- Instruct the patient that any abdominal pain, tenderness, or distention; pain on defecation; or fever must be reported to the HCP immediately.
- Inform the patient that any bloating or flatulence is the result of air insufflation.
- Encourage the patient to drink several glasses of water to help replace fluid lost during test preparation.
Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include barium enema, capsule endoscopy, colonoscopy, complete blood count, CT abdomen, fecal analysis, fecal fat, GI blood loss scan, MRI abdomen, and US prostate transrectal.
- Refer to the Gastrointestinal System table at the back of the book for related tests by body system.

**Progesterone**

**SYNONYM/ACRONYM:** N/A.

**DESCRIPTION:** Progesterone is a female sex hormone. Its function is to prepare the uterus for pregnancy and the breasts for lactation. Progesterone testing can be used to confirm that ovulation has occurred and to assess the functioning of the corpus luteum. Serial measurements can be performed to help determine the day of ovulation.
INDICATIONS:
• Assist in the diagnosis of luteal-phase defects (performed in conjunction with endometrial biopsy)
• Evaluate patients at risk for early or spontaneous abortion
• Identify patients at risk for ectopic pregnancy and assessment of corpus luteum function
• Monitor patients ovulating during the induction of human chorionic gonadotropin (HCG), human menopausal gonadotropin, follicle-stimulating hormone/luteinizing hormone–releasing hormone, or clomiphene (serial measurements can assist in pinpointing the day of ovulation)
• Monitor patients receiving progesterone replacement therapy

RESULT:
Increased in:
• Chorioepithelioma of the ovary (Progesterone-secreting tumor)
• Congenital adrenal hyperplasia (Excessive production of progesterone precursors)
• Hydatidiform mole (Progesterone-secreting tumor)
• Lipoid ovarian tumor (Progesterone-secreting tumor)
• Theca lutein cyst (Progesterone-secreting cyst)

Decreased in:
• Galactorrhea-amenorrhea syndrome (Progesterone is not produced in the absence of ovulation)
• Primary or secondary hypogonadism (Diminished production of progesterone)
• Short luteal phase syndrome (Diminished time frame for production and secretion)
• Threatened abortion (Decreased production by threatened placenta)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may increase progesterone levels include clomiphene, corticotropin, hydroxyprogesterone, ketoconazole, mifepristone, progesterone, tamoxifen, and valproic acid.
• Drugs that may decrease progesterone levels include ampicillin, epostane, goserelin, leuprolide, and prostaglandin F2a.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is primarily used to assess ovarian function, assist in fertility work-ups, and monitor placental function during pregnancy.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s endocrine and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
• If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
SYNONYM/ACRONYM: Luteotropic hormone, lactogenic hormone, lactogen, HPRL, PRL.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Specimen should be transported tightly capped and in an ice slurry.

REFERENCE VALUE: (Method: Immunoassay)

Prolactin

SYNONYM/ACRONYM: Luteotropic hormone, lactogenic hormone, lactogen, HPRL, PRL.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Specimen should be transported tightly capped and in an ice slurry.

REFERENCE VALUE: (Method: Immunoassay)

POST-TEST:
A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Recognize anxiety related to test results, and provide support. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide a nonjudgmental, nonthreatening atmosphere for exploring other options (e.g., adoption). Educate the patient regarding access to counseling services, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
Related tests include ACTH, AFP, amniotic fluid analysis, antibodies cardiolipin, biopsy chorionic villus, estradiol, fetal fibronectin, FSH, HCG, LH, prolactin, testosterone, and US BPP obstetric.

Refer to the Endocrine and Reproductive System tables at the back of the book for related tests by body system.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.
DESCRIPTION: Prolactin is secreted by the pituitary gland. It is unique among hormones in that it responds to inhibition by the hypothalamus rather than to stimulation. The only known function of prolactin is to induce milk production in female breasts that are already stimulated by high estrogen levels. When milk production is established, lactation can continue without elevated prolactin levels. Prolactin levels rise late in pregnancy, peak with the initiation of lactation, and surge each time a woman breast-feeds. The function of prolactin in males is unknown.

INDICATIONS:
- Assist in the diagnosis of primary hypothyroidism, as indicated by elevated levels
- Assist in the diagnosis of suspected tumor involving the lungs or kidneys (elevated levels indicating ectopic prolactin production)
- Evaluate failure of lactation in the postpartum period
- Evaluate sexual dysfunction of unknown cause in men and women
- Evaluate suspected postpartum hypophysal infarction (Sheehan’s syndrome), as indicated by decreased levels

RESULT:

**Increased in:**
- Adrenal insufficiency (Secondary to hypopituitarism)
- Amenorrhea (Pathophysiology is not well understood)
- Anorexia nervosa (Pathophysiology is not well understood)
- Breastfeeding (Stimulates secretion of prolactin)
- Chiari-Frommel and Argonz–Del Castillo syndromes (Endocrine disorders in which pituitary or hypothalamic tumors secrete excessive amounts of prolactin)
- Chest wall injury (Trauma in this location can stimulate production of prolactin)
- Chronic renal failure (Related to decreased renal excretion)
- Ectopic prolactin-secreting tumors (e.g., lung, kidney)
- Galactorrhea (Production of breast milk related to prolactin-secreting tumor)
- Hypothalamic and pituitary disorders
- Hypothyroidism (primary) (Related to pituitary gland dysfunction)
- Insulin-induced hypoglycemia (Insulin affects the release of pituitary hormones including prolactin)
- Liver failure
- Pituitary tumor
- Polycystic ovary (Stein-Leventhal) syndrome
- Pregnancy
- Surgery (pituitary stalk section)

**Decreased in:**
- Sheehan’s syndrome (Severe hemorrhage after obstetric delivery that causes pituitary infarct; secretion of all pituitary hormones is diminished)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs and hormones that may increase prolactin levels include amitryptyline, amoxapine, arginine, azosemide, benzerazide, butaperazine, butorphanol, carbidopa, chlorophenylpiperazine, chlorpromazine, cimetidine, clomipramine, desipramine, diethylstilbestrol, β-endorphin, enflurane, fenfluramine, fenoldopam, flunarizine, fluphenazine, growth hormone–releasing hormone, imipramine, insulin, interferon-b, labetalol, loxapine, megestrol, mestranol,
methyldopa, metoclopramide, molindone, morphine, nitrous oxide, oral contraceptives, oxcarbazepine, parathyroid hormone, pentagastrin, perphenazine, phenothiazines, phenytoin, pimozide, prochlorperazine, promazine, ranitidine, remoxipride, reserpine, sulpiride, sulpropride, thiethylperazine, thioridazine, thiothixene, thyrotropin-releasing hormone, trifluoperazine, trimipramine, tumor necrosis factor, verapamil, and zometapine.

• Drugs and hormones that may decrease prolactin levels include anticonvulsants, apomorphine, bromocriptine, cabergoline, calcitonin, cyclosporine, dexamethasone, dopamine, D-Trp-6-LHRH, levodopa, metoclopramide, morphine, nifedipine, octreotide, pergolide, ranitidine, rifampin, ritanserin, ropinirole, secretin, terguride, and thyroid hormones.

• Episodic elevations can occur in response to sleep, stress, exercise, hypoglycemia, and breastfeeding.

• Venipuncture can cause falsely elevated levels.

• Prolactin secretion is subject to diurnal variation, with highest levels occurring in the morning.

• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is primarily used to evaluate lactation disorders and identify the presence of prolactin-secreting tumors.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Specimen collection should occur between 8 and 10 a.m. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain there may be some discomfort during the venipuncture.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- The patient should fast for 12 hr before specimen collection.
- There are no fluid or medication restrictions, unless by medical direction.
- Prepare an ice slurry in a cup or plastic bag to have on hand for immediate transport of the specimen to the laboratory.

**INTRATEST:**
- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 12 hr prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.
The specimen should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag.

### POST-TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume usual diet, as directed by the HCP.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

### RELATED MONOGRAPHS:
- Refer to the Endocrine and Reproductive System tables at the back of the book for related tests by body system.

### PROSTATE-SPECIFIC ANTIGEN

**SYNONYM/ACRONYM:** PSA.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** (Method: Immunoassay)

<table>
<thead>
<tr>
<th>Gender</th>
<th>Conventional Units</th>
<th>SI Units (Conventional Units × 1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Male</td>
<td>Less than 4 ng/mL</td>
<td>Less than 4 mcg/L</td>
</tr>
<tr>
<td>Female</td>
<td>Less than 0.5 ng/mL</td>
<td>Less than 0.5 mcg/L</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Prostate-specific antigen (PSA) is produced exclusively by the epithelial cells of the prostate, periurethral, and perirectal glands. Used in conjunction with the digital rectal examination (DRE), PSA is a useful test for identifying and monitoring cancer of the prostate. PSA circulates in both free and bound (complexed) forms. A low ratio of free to complexed PSA (i.e., less than 10%) is suggestive of prostate cancer; a ratio of greater than 30% is rarely associated with prostate cancer. Serial measurements are often performed before and after surgery. PSA velocity, the rate of PSA increase over time, is being used to identify the potential aggressiveness of the cancer. Patients with an increase greater than 2.0 ng/mL in a year are more likely to have an aggressive form of prostate cancer with a greater risk of death. PSA is also produced in
females, most notably in breast tissue. There is some evidence that elevated PSA levels in breast cancer patients are associated with positive estrogen and progesterone status. **Important note:** When following patients using serial testing, the same method of measurement should be consistently used.

**INDICATIONS:**
- Evaluate the effectiveness of treatment for prostate cancer (prostatectomy): Levels decrease if treatment is effective; rising levels are associated with recurrence and a poor prognosis.
- Investigate or evaluate an enlarged prostate gland, especially if prostate cancer is suspected.
- Stage prostate cancer.

**RESULT:**
**Increased in:**
- A breach in the protective barrier between the prostatic lumen and the bloodstream due to significant disease will allow measurable levels of circulating PSA.
- Benign prostatic hypertrophy
- Prostate cancer
- Prostatic infarct
- Prostatitis
- Urinary retention

**Decreased in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that decrease PSA levels include buserelin, dutasteride, finasteride, and flutamide.
- Increases may occur if ejaculation occurs within 24 hr prior to specimen collection. Increases can occur due to prostatic needle biopsy, cystoscopy, prostatic infarction either by undergoing catheterization or the presence of an indwelling catheter, therefore specimens should be collected prior to or 6 wk after the procedure. There is conflicting information regarding the effect of DRE on PSA values and some health care providers (HCPs) may specifically request specimen collection prior to DRE.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to monitor status of prostate cancer and response to therapy.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s genitourinary, immune, and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the
Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Recognize anxiety related to test results, and offer support. Counsel the patient, as appropriate, that sexual dysfunction related to altered body function, drugs, or radiation may occur. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the National Cancer Institute (www.cancer.gov).

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. The National Cancer Society’s recommendations and American Urological Society’s Best Practice Policy on prostate cancer include annual screening for men over age 49 yr. Recommendations for men with an increased risk, such as African American males or males with a family history of prostate cancer, include annual screening over age 39 yr.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include biopsy prostate (including Gleason Score), cystoscopy, cystourethrograpy voiding, PAP, retrograde ureteropyelography, semen analysis, and US prostate.

- Refer to the Genitourinary, Immune, and Reproductive System tables at the back of the book for related tests by body system.

**Protein, Blood, Total and Fractions**

**SYNONYM/ACRONYM:** TP, SPEP (fractions include albumin, α₁-globulin, α₂-globulin, β-globulin, and γ-globulin).

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** (Method: Spectrophotometry for total protein, electrophoresis for protein fractions)
Total Protein

**DESCRIPTION:** Protein is essential to all physiological functions. Proteins consist of amino acids, the building blocks of blood and body tissues. Protein is also required for the regulation of metabolic processes, immunity, and proper water balance. Total protein includes albumin and globulins. \( \alpha_1 \)-Globulin includes \( \alpha_1 \)-antitrypsin, \( \alpha_1 \)-fetoprotein, \( \alpha_1 \)-acid glycoprotein, \( \alpha_1 \)-antichymotrypsin, inter-\( \alpha_1 \)-trypsin inhibitor, high-density lipoproteins, and group-specific component (vitamin D–binding protein). \( \alpha_2 \)-Globulin includes haptoglobin, ceruloplasmin, and \( \alpha_2 \)-macroglobulin. \( \beta \)-Globulin includes transferrin, hemopexin, very-low-density lipoproteins, low-density lipoproteins, \( \beta_2 \)-microglobulin, fibrinogen, complement, and C-reactive protein. \( \gamma \)-Globulin includes immunoglobulin (Ig) G, IgA, IgM, IgD, and IgE. After an acute infection or trauma, levels of many of the liver-derived proteins increase, whereas albumin level decreases; these conditions may not reflect an abnormal total protein determination.

**INDICATIONS:**
- Evaluation of edema, as seen in patients with low total protein and low albumin levels
- Evaluation of nutritional status

**RESULT:**

**Increased in:**
- \( \alpha_1 \)-Globulin proteins in acute and chronic inflammatory diseases
- \( \alpha_2 \)-Globulin proteins occasionally in diabetes, pancreatitis, and hemolysis
- \( \beta \)-Globulin proteins in hyperlipoproteinemias and monoclonal gammopathies
- \( \gamma \)-Globulin proteins in chronic liver diseases, chronic infections, autoimmune disorders, hepatitis, cirrhosis, and lymphoproliferative disorders

</table>
• Total protein:
  Dehydration (Hemoconcentration)
  Monoclonal and polyclonal gammopathies (Excessive gamma globulin protein synthesis)
  Myeloma (Excessive gamma globulin protein synthesis)
  Sarcoidosis (Mostly gamma globulins)
  Some types of chronic liver disease
  Tropical diseases (e.g., leprosy) (Related to inflammatory reaction)
  Waldenström’s macroglobulinemia (Mostly gamma globulins)

Decreased in:
• α1-Globulin proteins in hereditary deficiency
• α2-Globulin proteins in nephrotic syndrome, malignancies, numerous subacute and chronic inflammatory disorders, and recovery stage of severe burns
• β-Globulin proteins in hypo-b-lipoproteinemias and IgA deficiency
• γ-Globulin proteins in immune deficiency or suppression
• Total protein:
  Administration of IV fluids (Hemodilution)
  Burns (Related to fluid retention, loss of albumin from chronic open burns)
  Chronic alcoholism (Related to insufficient dietary intake; diminished protein synthesis by damaged liver)
  Chronic ulcerative colitis (Related to poor intestinal absorption)
  Cirrhosis (Damaged liver cannot synthesize adequate amount of protein)
  Crohn’s disease (Related to poor intestinal absorption)
  Glomerulonephritis (Related to alteration in permeability that results in excessive loss by kidneys)
  Heart failure (Related to fluid retention)
  Hyperthyroidism (Possibly related to increased metabolism and corresponding protein synthesis)

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is primarily used to evaluate nutritional status; abnormal values are found in numerous conditions and diseases.

Pregnancy (Related to fluid retention, dietary insufficiency, increased demands of growing fetus)
Prolonged immobilization (Related to fluid retention)
Protein-losing enteropathies (Related to excessive loss)
Severe skin disease
Starvation (Insufficient intake)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may increase protein levels include amino acids (if given IV), anabolic steroids, angiotensin, anticonvulsants, carbenicillin, corticosteroids, corticotropin, digitalis, furosemide, insulin, isotretinoin, levonorgestrel, oral contraceptives, progesterone, radiographic agents, and thyroid agents.
• Drugs and substances that may decrease protein levels include acetylsalicylic acid, arginine, benzene, carvedilol, citrates, floxuridine, laxatives, mercury compounds, oral contraceptives, pentastarch, phosgene, pyrazinamide, rifampin, trimethadione, and valproic acid.
• Values are significantly lower (5% to 10%) in recumbent patients.
• Hemolysis can falsely elevate results.
• Venous stasis can falsely elevate results; the tourniquet should not be left on the arm for longer than 60 sec.
Obtain a history of the patient’s complaints, including a list of known allergens especially allergies or sensitivities to latex.

Obtain a history of the patient’s gastrointestinal, hepatobiliary, and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**POST-TEST:**

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

**Nutritional considerations:** Educate the patient, as appropriate, that good dietary sources of complete protein (containing all eight essential amino acids) include meat, fish, eggs, and dairy products; and that good sources of incomplete protein (lacking one or more of the eight essential amino acids) include grains, nuts, legumes, vegetables, and seeds.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include albumin, ALP, ACE, anion gap, AST, biopsy liver, biopsy lung, calcium, carbon dioxide, chloride, complete blood count, complete blood count, WBC count and differential, cryoglobulin, fecal analysis, fecal fat, gallium scan, GGT, IgA, IgG, IgM, IFE, liver and spleen scan, magnesium, mediastinoscopy, β₂-microglobulin, osmolality, protein urine total and fractions, PFT, radiography bone, RF, sodium, TSH, thyroxine, and UA.

Refer to the Gastrointestinal, Hepatobiliary, and Immune System tables at the back of the book for related tests by body system.

**INTRATEST:**

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.
Protein C

SYNONYM/ACRONYM: Protein C antigen, protein C functional.

SPECIMEN: Plasma (1 mL) collected in blue-top (sodium citrate) tube.

REFERENCE VALUE: (Method: Chromogenic) 70% to 140% activity. Values are significantly reduced in children because of liver immaturity.

DESCRIPTION: Protein C is a vitamin K–dependent protein that originates in the liver and circulates in plasma. Protein C activation occurs on thrombomodulin receptors on the endothelial cell surface. Thrombin bound to thrombomodulin receptors preferentially activates protein C. Freely circulating thrombin mainly converts fibrinogen to fibrin. Other steps in the activation process require calcium and protein S cofactor binding (see monographs titled “Protein S” and “Fibrinogen”). Activated protein C exhibits potent anticoagulant effects by degrading activated factors V and VIII. Factor V Leiden is a genetic variant of Factor V and is resistant to inactivation by protein C. Factor V Leiden is the most common inherited hypercoagulability disorder identified among individuals of Eurasian descent. There are two types of protein C deficiency:

- **Type I:** Decreased antigen and function, detected by functional and antigenic assays
- **Type II:** Normal antigen but decreased function, detected only by a functional assay

Functional assays are recommended for initial evaluation because of their greater sensitivity.

INDICATIONS:
- Differentiate inherited deficiency from acquired deficiency
- Investigate the mechanism of idiopathic venous thrombosis

RESULT:
- **Increased in:** N/A
- **Decreased in:**
  - Congenital deficiency
  - Liver disease *(Related to decreased synthesis by the liver)*
  - Oral anticoagulant therapy *(Patients deficient in protein C may be at risk of developing Coumadin®-induced skin necrosis)*

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs that may increase protein C levels include desmopressin and oral contraceptives.
- Drugs that may decrease protein C levels include coumarin and warfarin (Coumadin).
- Placement of tourniquet for longer than 1 min can result in venous stasis and changes in the concentration of plasma proteins to be measured. Platelet activation may also occur under these conditions, causing erroneous results.
- Vascular injury during phlebotomy can activate platelets and coagulation factors, causing erroneous results.

Access additional resources at davisplus.fadavis.com
Hemolyzed specimens must be rejected because hemolysis is an indication of platelet and coagulation factor activation.

Incompletely filled tubes contaminated with heparin or clotted specimens must be rejected.

Icteric or lipemic specimens interfere with optical testing methods, producing erroneous results.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess anticoagulant function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRA-TEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in

**APPENDIX A**

Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. **Important note:** Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It is important to ask the laboratory which concentration it recommends, because each concentration will have its own specific reference range.

When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and red-top tubes. When coagulation testing is the only work to be done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with tissue thromboplastin, which can falsely decrease values.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage. Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed samples stored in unopened tubes is that testing should be completed within 1 to 4 hr of collection. If the patient has a known hematocrit above 55%, adjust the amount of anticoagulant in the collection tube before drawing the blood according to the CLSI guidelines:

\[
\text{Anticoagulant vol. [x]} = \frac{(100 - \text{hematocrit})/595 - \text{hematocrit}}{\text{total vol. of anticoagulated blood required}}
\]

**Example:**

Patient hematocrit = 60% (100 - 60)/(595 - 60) \times 5.0 = 0.37 mL sodium citrate for a 5-mL standard drawing tube
**Post-Test:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**Related Monographs:**

- Related tests include antibody, anticardiolipin, antithrombin III, calcium, complete blood count, coagulation factors (factor V), FDP, fibrinogen, lupus anticoagulant, aPTT, protein S, PT/INR, and vitamin K.
- Refer to the Hematopoietic and Hepatobiliary System tables at the back of the book for related tests by body system.

---

**Protein S**

**Synonym/Acronym:** Protein S antigen, protein S functional.

**Specimen:** Plasma (1 mL) collected in blue-top (sodium citrate) tube.

**Reference Value:** (Method: Clot detection)

*Note: The low end of “normal” is lower in children younger than age 16 because of the immaturity of the liver.*

**Description:** Protein S is a vitamin K–dependent protein that originates in the liver and circulates in plasma. It is a cofactor required for the activation of protein C (see monographs titled “Protein C” and “Fibrinogen”). Protein S exists in two forms, free (biologically active) and bound. Approximately 40% of protein S circulates in the free form; the remainder is bound and is functionally inactive. There are two types of protein S deficiency:

- **Type I:** Decreased antigen and function, detected by functional and antigenic assays
- **Type II:** Normal antigen but decreased function, detected only by a functional assay

Functional assays are recommended for initial evaluation because of their greater sensitivity.

**Indications:**

Investigate the cause of hypercoagulable states.

**Result:**

*Increased in:* N/A

*Decreased in:*
- Congenital deficiency
- Disseminated intravascular coagulation (DIC) *(Consumed in DIC)*

Access additional resources at davisplus.fadavis.com
- Liver disease (*Related to decreased synthesis by the liver*)
- Oral anticoagulant therapy

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may decrease protein S levels include coumarin, oral contraceptives, and warfarin (Coumadin®).
- Placement of tourniquet for longer than 1 min can result in venous stasis and changes in the concentration of plasma proteins to be measured. Platelet activation may also occur under these conditions, causing erroneous results.
- Vascular injury during phlebotomy can activate platelets and coagulation factors, causing erroneous results.

- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. *Important note:* Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It is important to ask the laboratory which concentration it recommends, because each concentration will have its own specific reference range.
- When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and red-top tubes. When coagulation testing is the only work to be done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with
tissue thromboplastin, which can falsely decrease values.

- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed samples stored in unopened tubes is that testing should be completed within 1 to 4 hr of collection. If the patient has a known hematocrit above 55%, adjust the amount of anticoagulant in the collection tube before drawing the blood according to the CLSI guidelines:

\[
\text{Anticoagulant vol. } [x] = \frac{(100 - \text{hematocrit})}{(595 - \text{hematocrit})} \times \text{total vol. of anticoagulated blood required.}
\]

Example:

Patient hematocrit = 60%

\[
(100 - 60)/(595 - 60) \times 5.0 = 0.37 \text{ mL sodium citrate for a 5–mL standard drawing tube}
\]

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related laboratory tests include, anticardiolipin antibody, AT-III, calcium, complete blood count, coagulation factors (factor V), FDP, fibrinogen, lupus anticoagulant, aPTT, protein C, PT/INR, and vitamin K.
- Refer to the Hematopoietic and Hepatobiliary System tables at the back of the book for related tests by body system.

---

**Protein, Urine: Total Quantitative and Fractions**

**SYNONYM/ACRONYM:** None.

**SPECIMEN:** Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

**REFERENCE VALUE:** (Method: Spectrophotometry for total protein, electrophoresis for protein fractions)

<table>
<thead>
<tr>
<th>Conventional Units</th>
<th>SI Units (Conventional Units × 0.001)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total protein</td>
<td>30–150 mg/24 h</td>
</tr>
</tbody>
</table>

Electrophoresis for fractionation is qualitative: No monoclonal gammopathy detected. (Urine protein electrophoresis should be ordered along with serum protein electrophoresis.)
**DESCRIPTION:** Most proteins, with the exception of the immunoglobulins, are synthesized and catabolized in the liver, where they are broken down into amino acids. The amino acids are converted to ammonia and ketoacids. Ammonia is converted to urea via the urea cycle. Urea is excreted in the urine.

**INDICATIONS:**
- Assist in the detection of Bence Jones proteins (light chains)
- Assist in the diagnosis of myeloma, Waldenström’s macroglobulinemia, lymphoma, and amyloidosis
- Evaluate kidney function

**RESULT:**

*Increased in:*
- Diabetic nephropathy (*Disease involving renal glomeruli affects increases permeability of protein*)
- Fanconi’s syndrome (*Abnormal protein deposits in the kidney can cause Fanconi’s syndrome*)
- Heavy metal poisoning (*Disease involving renal glomeruli affects increases permeability of protein*)
- Malignancies of the urinary tract (*The tumors secrete protein into the urine*)
- Monoclonal gammopathies (*Large amounts of Bence Jones protein light chains are excreted in the urine*)
- Multiple myeloma (*Large amounts of Bence Jones protein light chains are excreted in the urine*)
- Nephrotic syndrome (*Disease involving renal glomeruli increases permeability of protein*)
- Postexercise period (*Related to muscle exertion*)

*Preeclampsia (Numerous factors contribute to increased permeability of the kidneys to protein)*
- Sickle cell disease (*Related to increased destruction of red blood cells and excretion of hemoglobin protein*)
- Urinary tract infections (*Disease involving renal glomeruli affects increases permeability of protein*)

**Decreased in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs and substances that may increase urine protein levels include acetaminophen, aminosalicylic acid, amphotericin B, ampicillin, antimony compounds, antipyrine, arsenicals, ascorbic acid, bacitracin, bismuth subsalicylate, bromate, capreomycin, captopril, carbamazepine, carbarsone, carbonoxolone, carbutamide, cephaloglycin, cephaloridine, chlorpromazine, chlorpropamide, chlorothalidone, chrysarobin, colistimethate, colistin, corticosteroids, cyclosporine, demeclocycline, 1, 2-diaminopropane, diatrizoic acid, dihydrotachysterol, doxycycline, enalapril, gentamicin, gold, hydrogen sulfide, iodoalphonic acid, iodopyracet, iopanoic acid, iophenoxic acid, ipodate, kanamycin, corn oil (Lipomul), lithium, mefenamic acid, melarsonyl, melarsoprol, mercury compounds, methicillin, methylbromide, mezlocillin, mitomycin, nafillin, naphthalene, neomycin, nonsteroidal anti-inflammatory drugs, oxacillin, paraaldehyde, penicillamine, penicillin, phenolphthalein, phenols, phensuximide, phosphorus, picric acid, piperacillin, plicamycin, polymyxin, promazine, pyrazolones,
quaternary ammonium compounds, radiographic agents, rifampin, sodium bicarbonate, streptokinase, sulfisoxazole, suramin, tetracyclines, thallium, thiosemicarbazones, tolbutamide, tolmetin, triethylenemelamine, and vitamin D.

• Drugs that may decrease urine protein levels include captopril, cyclosporine, diltiazem, enalapril, fosinopril, interferon, lisinopril, prednisolone, and quinapril.
• All urine voided for the timed collection period must be included in the collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

PREREQUISITES:

Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
Inform the patient that the test is used to identify the underlying cause for proteinuria.
Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
Obtain a history of the patient’s genitourinary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.
Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that

24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
There are no food, fluid, or medication restrictions, unless by medical direction.

INSTRUCTIONS:

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
Instruct the patient to cooperate fully and to follow directions.
Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

Random Specimen (Collect in Early Morning):

Clean-Catch Specimen:
Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.
**Indwelling Catheter:**
- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

**Timed Specimen:**
- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than the recorded output, some urine may have been discarded, invalidating the test.
- Include on the collection container’s label the amount of urine collected and test start and stop times.

**General:**
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related laboratory tests include amino acid screen, ACE, β2-microglobulin, biopsy bladder, biopsy bone marrow, bladder cancer markers, BUN, calcium, complete blood count, CT pelvis, CT renal, creatinine, cryoglobulin, culture urine, cytology urine, cystometry, cystoscopy, glucose, glycated hemoglobin, Hgb electrophoresis, IgA, IgG, IgM, IFE, IVP, lead, LAP, MRI musculoskeletal, microalbumin, osmolality, porphyrins, protein blood total and fractions, renogram, sickle cell screen, US bladder, US spleen, UA, and voiding cystourethrography.
- Refer to the Genitourinary and Immune System tables at the back of the book for related tests by body system.
**Prothrombin Time and International Normalized Ratio**

**SYNONYM/ACRONYM:** Protime, PT.

**SPECIMEN:** Plasma (1 mL) collected in a completely filled blue-top (sodium citrate) tube.

**REFERENCE VALUE:** (Method: Clot detection) 10 to 13 sec.

International Normalized Ratio (INR) = Less than 2.0 for patients not receiving anticoagulation therapy, 2.0 to 3.0 for patients receiving treatment for venous thrombosis, pulmonary embolism, and valvular heart disease.

INR = 2.5 to 3.5 for patients with mechanical heart valves and/or receiving treatment for recurrent systemic embolism.

**DESCRIPTION:** Prothrombin time (PT) is a coagulation test performed to measure the time it takes for a firm fibrin clot to form after tissue thromboplastin (factor III) and calcium are added to the sample. It is used to evaluate the extrinsic pathway of the coagulation sequence in patients receiving oral warfarin or coumarin-type anticoagulants. Prothrombin is a vitamin K-dependent protein produced by the liver; measurement is reported as time in seconds or percentage of normal activity.

The goal of long-term anticoagulation therapy is to achieve a balance between in vivo thrombus formation and hemorrhage. It is a delicate clinical balance and due to differences in instruments and reagents there is a wide variation in PT results between laboratories. Worldwide concern for the need to provide more consistency in monitoring patients receiving anticoagulant therapy led to the development of an international committee. In the early 1980s, manufacturers of instruments and reagents began comparing their measurement systems with a single reference material provided by the World Health Organization (WHO). The international effort successfully developed an algorithm to provide comparable PT values regardless of differences in laboratory methodology. Reagent and instrument manufacturers compare their results to the WHO reference and derive a factor called an International Sensitivity Index (ISI) that is applied to a mathematical formula to standardize the results. Laboratories convert their PT values into an International Normalized Ratio (INR) by using the following formula:

\[
\text{INR} = \left( \frac{\text{patient PT result}}{\text{normal patient average}} \right)^{\text{ISI}}
\]

PT evaluation can now be based on an INR using a standardized thromboplastin reagent to assist in making decisions regarding oral anticoagulation therapy.

Some inferences of factor deficiency can be made by...
comparison of results obtained from the activated partial thromboplastin time (aPTT) and PT tests. A normal aPTT with a prolonged PT can occur only with factor VII deficiency. A prolonged aPTT with a normal PT could indicate a deficiency in factors XII, XI, IX, and VIII as well as VIII:C (von Willebrand factor). Factor deficiencies can also be identified by correction or substitution studies using normal serum. These studies are easy to perform and are accomplished by adding plasma from a normal patient to a sample from a suspected factor-deficient patient. When the PT is repeated and corrected, or within the reference range, it can be assumed that the prolonged PT is due to a factor deficiency (see monograph titled “Coagulation Factors”). If the result remains uncorrected, the prolonged PT is most likely due to a circulating anticoagulant.

**INDICATIONS:**
- Differentiate between deficiencies of clotting factors II, V, VII, and X, which prolong the PT; and congenital coagulation disorders, such as hemophilia A (factor VIII) and hemophilia B (factor IX), which do not alter the PT
- Evaluate the response to anticoagulant therapy with coumarin derivatives and determine dosage required to achieve therapeutic results
- Identify individuals who may be prone to bleeding during surgical, obstetric, dental, or invasive diagnostic procedures
- Identify the possible cause of abnormal bleeding, such as epistaxis, hematoma, gingival bleeding, hematuria, and menorrhagia
- Monitor the effects of conditions such as liver disease, protein deficiency, and fat malabsorption on hemostasis
- Screen for prothrombin deficiency
- Screen for vitamin K deficiency

**RESULT:**

*Increased in:*
- Afibrinogenemia, dysfibrinogenemia, or hypofibrinogenemia
  *(Fibrinogen is required for clotting and its absence will prolong PT)*
- Biliary obstruction *(Related to poor absorption of fat-soluble vitamin K; vitamin K is required for clotting and its absence will prolong PT)*
- Disseminated intravascular coagulation *(Clotting factors are consumed and PT is prolonged)*
- Hereditary deficiencies of factors II, V, VII, and X *(Factors are required for clotting; in their absence PT will be prolonged)*
- Liver disease (cirrhosis) *(Clotting factors are made in the liver; decreased liver function will result in decreased production of clotting factors and prolonged PT)*
- Poor fat absorption *(Tropical sprue, celiac disease, chronic diarrhea are conditions that prevent absorption of fat-soluble vitamins including vitamin K which is required for clotting; absence of vitamin K will prolong PT)*
- Presence of circulating anticoagulant *(Inhibitors of specific factors, e.g., developed from long-term Factor VIII therapy or circulating anticoagulants associated with conditions like tuberculosis, systemic lupus erythematosus, rheumatoid arthritis, and chronic glomerulonephritis)*
• Vitamin K deficiency (Vitamin K is required for clotting and its absence will prolong PT)

**Decreased in:**
- Ovarian hyperfunction
- Regional enteritis or ileitis

**CRITICAL VALUES:**

**INR:**
Greater than 5

**Prothrombin Time:**
Greater than 27 sec

Note and immediately report to the health care provider (HCP) any critically increased values and related symptoms. Important signs to note are prolonged bleeding from cuts or gums, hematoma at a puncture site, hemorrhage in the stool, persistent epistaxis, heavy or prolonged menstrual flow, and shock. Monitor vital signs, unusual ecchymosis, occult blood, severe headache, unusual dizziness, and neurological changes until PT is within normal range. Intramuscular administration of vitamin K, an anticoagulant reversal agent, may be requested by the HCP.

**INTERFERING FACTORS:**

• Drugs that may increase the PT in patients receiving anticoagulation therapy include acetaminophen, acetylsalicylic acid, amiodarone, anabolic steroids, anisindione, anistreplase, antibiotics, antipyrine, carbencillin, cathartics, chloralhydrane, cholestyramine, clofibrate, corticotropin, demeclocycline, dextrothyroxine, diazoxide, diflunisal, diuretics, doxycycline, erythromycin, glucagon, hydroxyzine, indomethacin, laxatives, mercaptopurine, miconazole, nalidixic acid, neomycin, niacin, oxyphenbutazone, phenytion, quinine, sul-fachlorpyridazine, and thyroxine.

• Drugs that may decrease the PT in patients receiving anticoagulation therapy include amobarbital, anabolic steroids, antacids, antihistamines, barbiturates, carbamazepine, chlordane, colchicine, corticosteroids, diuretics, oral contraceptives, penicillin, primidone, rifampin, simethicone, spironolactone, tolbutamide, and vitamin K.

• Traumatic venipunctures can activate the coagulation sequence by contaminating the sample with tissue thromboplastin, and producing falsely shortened PT.

• Failure to fill the tube sufficiently to yield proper blood-to-anticoagulant ratio may cause a falsely lengthened PT; an incompletely filled tube is reason for specimen rejection.

• Excessive agitation causing sample hemolysis can falsely shorten the PT because the hemolyzed cells activate plasma-clotting factors.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate the coagulation system and monitor anticoagulation therapy.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular, hematopoietic, and hepatobiliary systems, especially any bleeding disorders and other symptoms, as well as results of previously performed laboratory tests, diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number...
of days prior to a surgical procedure. Note the last time and dose of medication taken.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. Fill tube completely. *Important note:* Two different concentrations of sodium citrate preservative are currently added to blue-top tubes for coagulation studies: 3.2% and 3.8%. The Clinical and Laboratory Standards Institute/CLSI (formerly the National Committee for Clinical Laboratory Standards/NCCLS) guideline for sodium citrate is 3.2%. Laboratories establish reference ranges for coagulation testing based on numerous factors, including sodium citrate concentration, test equipment, and test reagents. It is important to ask the laboratory which concentration it recommends, because each concentration will have its own specific reference range.

When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) and red-top tubes. When coagulation testing is the only work to be done, an extra red-top tube should be collected before the blue-top tube to avoid contaminating the specimen with tissue thromboplastin, which can falsely shorten PT/INR.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed samples stored in unopened tubes is that testing should be completed within 1 to 4 hr of collection.

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to report bleeding from any areas of the skin or mucous membranes.

Inform the patient with prolonged PT/INR of the importance of taking precautions against bruising and bleeding, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of aspirin products, and avoidance of intramuscular injections.

Inform the patient of the importance of periodic laboratory testing while taking an anticoagulant.

**Nutritional considerations:** Foods high in vitamin K should be avoided by the patient on anticoagulant therapy. Foods that contain vitamin K include cabbage, cauliflower, chickpeas, egg yolks, green tea, liver, milk, soybean products, tomatoes, and green leafy vegetables such as brussels sprouts, kale, spinach, and turnip greens.

**Nutritional considerations:** Avoid alcohol and alcohol products while taking warfarin, as the combination of the two increases the risk of gastrointestinal bleeding.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process.
PSEUDOCHOLINESTERASE AND DIBUCAINE NUMBER

and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include, ALP, ALT, ANA, AT-III, AST, bilirubin, biopsy liver, bleeding time, calcium, coagulation factors, complete blood count, complete blood count, platelet count, CT liver and biliary tract, cryoglobulin, D-dimer, fecal analysis, fecal fat, FDP, fibrinogen, GGT, gastric acid emptying scan, hepatitis antibodies (A, B, C, D), liver and spleen scan, lupus anticoagulant, aPTT, plasminogen, protein C, protein S, US liver, and vitamin K.
- Refer to the Cardiovascular, Hematopoietic, and Hepatobiliary System tables at the back of the book for related tests by body system.

Pseudocholinesterase and Dibucaine Number

SYNONYM/ACRONYM: CHS, PCHE, AcCHS.

SPECIMEN: Plasma (1 mL) collected in a lavender-top (EDTA) tube. Serum (1 mL) collected in a red-top tube is also acceptable.

REFERENCE VALUE: (Method: Spectrophotometry, kinetic)

RESULT:

**Increased in:**

Increased levels are observed in a number of conditions without specific cause.
- Diabetes
- Hyperthyroidism
- Nephrotic syndrome
- Obesity

**Decreased in:**

The enzyme is produced in the liver and any condition affecting liver function may result in decreased production of circulating enzyme.
- Acute infection
- Anemia (severe)
- Carcinomatosis
- Cirrhosis
- Congenital deficiency
Pulmonary Function Studies

SYNONYM/ACRONYM: Pulmonary function tests (PFTs).

AREA OF APPLICATION: Lungs, respiratory system.

CONTRAST: None.

DESCRIPTION: Pulmonary function studies provide information about the volume, pattern, and rates of airflow involved in respiratory function. These studies may also include tests involving the diffusing capabilities of the lungs (i.e., volume of gases diffusing across a membrane). A complete pulmonary study profile includes the determination of all lung volumes, spirometry, diffusing capacity, maximum voluntary ventilation, flow-volume loop (Fig. 1–1), and maximum expiratory and inspiratory pressures. Other studies include small airway volumes.

Pulmonary function studies are classified according to lung volumes and capacities, rates of flow, and gas exchange. The exception is the diffusion test, which records the movement of a gas during inspiration and expiration. Lung volumes and capacities constitute the amount of air inhaled or exhaled from the lungs; this value is compared to normal reference values specific for the patient’s age, height, and gender. The following are volumes and capacities measured by spirometry that do not require timed testing.

Find and print out the full monograph at DavisPlus (davisplus.fadavis.com, keyword Van Leeuwen).

- Hepatic carcinoma
- Hepatocellular disease
- Infectious hepatitis
- Insecticide exposure (Organic phosphate exposure decreases enzyme activity)
- Malnutrition (Possibly related to decreased availability of transport proteins; condition associated with decreased enzyme activity)
- Muscular dystrophy
- Myocardial infarction
- Plasmapheresis (Iatrogenic cause)
- Succinylcholine hypersensitivity (This chemical is a trigger in susceptible individuals)
- Tuberculosis (Chronic infection is known to decrease enzyme activity)
- Uremia (Pathological condition is known to decrease enzyme activity)

CRITICAL VALUES: Notify the anesthesiologist if the test result is positive and surgery is scheduled. A positive result indicates that the patient is at risk for prolonged or unrecoverable apnea related to the inability to metabolize succinylcholine.
**Pulmonary Function Studies**

**Tidal Volume:**
Total amount of air inhaled and exhaled with one breathe.

**Residual Volume:**
Amount of air remaining in the lungs after a maximum expiration effort (not measured by spirometry, but can be calculated from the functional residual capacity [FRC] minus the expiratory reserve volume [ERV]). This indirect type of measurement can be done by body plethysmography (see monograph titled "Plethysmography").

**Inspiratory Reserve Volume:**
Maximum amount of air inhaled after normal inspirations.

**Expiratory Reserve Volume:**
Maximum amount of air exhaled after a resting expiration (can be calculated by the vital capacity [VC] minus the inspiratory capacity [IC]).

**Vital Capacity:**
Maximum amount of air exhaled after a maximum inspiration (can be calculated by adding the IC and the ERV).

**Total Lung Capacity:**
Total amount of air that the lungs can hold after maximal inspiration (can be calculated by adding the VC and the residual volume [RV]).

**Inspiratory Capacity:**
Maximum amount of air inspired after normal expiration (can be calculated by adding the inspiratory RV and tidal volume).

**Functional Residual Capacity:**
Volume of air that remains in the lungs after normal expiration (can be calculated by adding the RV and ERV).

The volumes, capacities, and rates of flow measured by spirometry that do require timed testing include the following:

**Forced Vital Capacity in 1 Second:**
Maximum amount of air that can be forcefully exhaled after a full inspiration.

**Forced Expiratory Volume:**
Amount of air exhaled in the first second (can also be determined at 2 or 3 seconds) of forced vital capacity (FVC, which is the amount of air exhaled in seconds, expressed as a percentage).

**Maximal Midexpiratory Flow:**
Also known as forced expiratory flow rate (FEF$_{25-75}$), or the maximal rate of airflow during a forced expiration.

**Forced Inspiratory Flow Rate:**
Volume inspired from the RV at a point of measurement (can be calculated by adding the IC and the tidal volume).
expressed as a percentage to identify the corresponding volume pressure and inspired volume).

**Peak Inspiratory Flow Rate:**
Maximum airflow during a forced maximal inspiration.

**Peak Expiratory Flow Rate:**
Maximum airflow expired during FVC.

**Flow-Volume Loops:**
Flows and volumes recorded during forced expiratory volume and forced inspiratory vital capacity procedures (Fig. 1–2).

**Maximal Inspiratory-Expiratory Pressures:**
Measures the strength of the respiratory muscles in neuromuscular disorders.

**Maximal Voluntary Ventilation:**
Maximal volume of air inspired and expired in 1 min (may be done for shorter periods and multiplied to equal 1 min).

Other studies for gas-exchange capacity, small airway abnormalities, and allergic responses in hyperactive airway disorders can be performed during the conventional pulmonary function study. These include the following:

**Diffusing Capacity of the Lungs:**
Rate of transfer of carbon monoxide through the alveolar and capillary membrane in 1 minute.

**Closing Volume:**
Measures the closure of small airways in the lower alveoli by monitoring volume and percentage of alveolar nitrogen after inhalation of 100% oxygen.

**Isoflow Volume:**
Flow-volume loop test followed by inhalation of a mixture of helium and oxygen to determine small airway disease.
**Body Plethysmography:**
Measures thoracic gas volume and airway resistance.

**Bronchial Provocation:**
Quantifies airway response after inhalation of methacholine.

**Arterial Blood Gases:**
Measure oxygen, pH, and carbon dioxide in arterial blood.
Values are expressed in units of mL, %, L, L/sec, and L/min, depending on the test performed.

**INDICATIONS:**
- Detect chronic obstructive pulmonary disease (COPD) and/or restrictive pulmonary diseases that affect the chest wall (e.g., neuromuscular disorders, kyphosis, scoliosis) and lungs, as evidenced by abnormal airflows and volumes
- Determine airway response to inhalants in patients with an airway-reactive disorder
- Determine the diffusing capacity of the lungs (DCOL)
- Determine the effectiveness of therapy regimens, such as bronchodilators, for pulmonary disorders
- Determine the presence of lung disease when other studies, such as x-rays, do not provide a definitive diagnosis, or determine the progression and severity of known COPD and restrictive pulmonary disease
- Evaluate the cause of dyspnea occurring with or without exercise
- Evaluate lung compliance to determine changes in elasticity, as evidenced by changes in lung volumes (decreased in restrictive pulmonary disease, increased in COPD and in elderly patients)
- Evaluate pulmonary disability for legal or insurance claims
- Evaluate pulmonary function after surgical pneumonectomy, lobectomy, or segmental lobectomy
- Evaluate the respiratory system to determine the patient’s ability to tolerate procedures such as surgery or diagnostic studies
- Screen high-risk populations for early detection of pulmonary conditions (e.g., patients with exposure to occupational or environmental hazards, smokers, patients with a hereditary predisposition)

**RESULT:**

**Normal findings in:**
- Normal respiratory volume and capacities, gas diffusion, and distribution
- No evidence of COPD or restrictive pulmonary disease

Normal adult lung volumes, capacities, and flow rates are as follows:

*(table continues on page 1016)*
Abnormal findings in:
• Allergy
• Asbestosis
• Asthma
• Bronchiectasis
• Chest trauma
• Chronic bronchitis
• Curvature of the spine
• Emphysema
• Myasthenia gravis
• Obesity
• Pulmonary fibrosis
• Pulmonary tumors
• Respiratory infections
• Sarcoidosis

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• The aging process can cause decreased values (FVC, DCOL) depending on the study done.
• Inability of the patient to put forth the necessary breathing effort affects the results.
• Medications such as bronchodilators can affect results.
• Improper placement of the nose clamp or mouthpiece that allows for leakage can affect volume results.

Note: Normal values listed are estimated values for adults. Actual pediatric and adult values are based on age, height, and gender. These normal values are included on the patient’s pulmonary function laboratory report.

TV = tidal volume; RV = residual volume; IRV = inspiratory reserve volume; ERV = expiratory reserve volume; VC = vital capacity; TLC = total lung capacity; IC = inspiratory capacity; FRC = functional residual capacity; FVC = forced vital capacity in 1 second; FEV₁ = forced expiratory volume in 1 second; MMEF = maximal midexpiratory flow (also known as $\text{FEF}_{25-75}$); FIF = forced inspiratory flow rate; MVV = maximal voluntary ventilation; PIFR = peak inspiratory flow rate; PEFR = peak expiratory flow rate; F-V loop = flow-volume loop; DCOL = diffusing capacity of the lungs; CV = closing volume; $V_{iso}$ = isoflow volume.

Confusion or inability to understand instructions or cooperate during the study can cause inaccurate results.

Testing is contraindicated in patients with cardiac insufficiency, recent myocardial infarction, and presence of chest pain that affects inspiration or expiration ability.

Exercise caution with patients who have upper respiratory infections, such as a cold or acute bronchitis.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses lung functions.
• Obtain a history of the patient’s complaints or symptoms, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast mediums.
• Obtain a history of the patient’s cardiovascular and respiratory systems,
PULMONARY FUNCTION STUDIES

1. Symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
2. Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
3. Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that no discomfort will be experienced during the test. Explain that the procedure is generally performed in a specially equipped room or in a health care provider’s (HCP’s) office by a HCP specializing in this procedure and usually lasts 1 hr.
4. Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
5. Record the patient’s height and weight.
6. The patient should avoid bronchodilators (oral or inhalant) for at least 4 hr before the study, as directed by the HCP.
7. Instruct the patient to refrain from smoking tobacco or eating a heavy meal for 4 to 6 hr prior to the study.

INTRATEST:

- Ensure the patient has complied with dietary and medication restrictions and pretesting preparations.
- Obtain an inhalant bronchodilator to treat any bronchospasms that may occur with testing.
- Instruct the patient to void and to loosen any restrictive clothing.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in a sitting position on a chair near the spirometry equipment.
- Place a soft clip on the patient’s nose to restrict nose breathing, and instruct the patient to breathe through the mouth.
- Place a mouthpiece in the mouth and instruct the patient to close his or her lips around it to form a seal.
- Tubing from the mouthpiece is connected to a cylinder that is connected to a computer that measures, records, and calculates the values for the tests done.
- Instruct the patient to inhale deeply and then to quickly exhale as much air as possible into the mouthpiece.

Additional breathing maneuvers are performed on inspiration and expiration (normal, forced, and breath-holding).

POST-TEST:

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Assess the patient for dizziness or weakness after the testing.
- Allow the patient to rest as long as needed to recover.
- Instruct the patient to resume usual diet and medications, as directed by the HCP.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
- Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy.

RELATED MONOGRAPHS:

- Related tests include α1-AT, anion gap, arterial/alveolar oxygen ratio, biopsy lung, blood gases, bronchoscopy, carboxyhemoglobin, chest x-ray, chloride sweat, complete blood count, complete blood count, WBC hemoglobin, complete blood count, WBC count and differential, CT angiography, CT thoracic, culture and smear for mycobacteria, culture bacterial sputum, culture viral, cytology sputum, echocardiography, ECG, gram stain, IgE, lactic acid, lung perfusion scan, lung ventilation scan, MR angiography, MRI chest, osmolality, phosphorus, plethysmography, pleural fluid analysis, potassium, PET chest, pulse oximetry, sodium, and TB skin test.
- Refer to the Cardiovascular and Respiratory Systems tables in the back of the book for related tests by body system.

Pulse Oximetry

SYNONYM/ACRONYM: Oximetry, Pulse Ox.

AREA OF APPLICATION: Earlobe, fingertip; for infants, use the large toe, top or bottom of the foot, or sides of the ankle.

CONTRAST: None.

DESCRIPTION: Pulse oximetry is a noninvasive study that provides continuous readings of arterial blood oxygen saturation (SPO2) using a sensor site (earlobe or fingertip). The SPO2 equals the ratio of the amount of O2 contained in the hemoglobin to the maximum amount of O2 contained with hemoglobin expressed as a percentage. The results obtained may compare favorably with O2 saturation levels obtained by arterial blood gas analysis without the need to perform successive arterial punctures. The device used is a clip or probe that produces a light beam with two different wavelengths on one side. A sensor on the opposite side measures the absorption of each of the wavelengths of light to determine the O2 saturation reading. The displayed result is a ratio, expressed as a percentage, between the actual O2 content of the hemoglobin and the potential maximum O2-carrying capacity of the hemoglobin.

INDICATIONS:
- Monitor oxygenation during testing for sleep apnea
- Monitor oxygenation perioperatively and during acute illnesses
- Monitor oxygenation status in patients on a ventilator, during surgery, and during bronchoscopy
- Monitor O2 saturation during activities such as pulmonary exercise stress testing or pulmonary rehabilitation exercises to determine optimal tolerance
- Monitor response to pulmonary drug regimens, especially flow and O2 content

RESULT:

Normal findings in:
- Greater than or equal to 95%

Abnormal findings in:
- Abnormal gas exchange
- Hypoxemia with levels less than 95%
- Impaired cardiopulmonary function

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients who smoke or have suffered carbon monoxide inhalation, because O2 levels may be falsely elevated

Factors that may impair clear imaging:
- Patients with anemic conditions reflecting a reduction in
Pulse Oximetry

Hemoglobin, the O₂-carrying component in the blood

- Excessive light surrounding the patient, such as from surgical lights
- Impaired cardiopulmonary function
- Lipid emulsion therapy and presence of certain dyes
- Movement of the finger or ear or improper placement of probe or clip
- Nail polish, false fingernails, and skin pigmentation when a finger probe is used
- Vasoconstriction from cool skin temperature, drugs, hypotension, or vessel obstruction causing a decrease in blood flow

Other considerations:
- Accuracy for most units is plus or minus 4% with a standard deviation of 1%

Nursing Implications and Procedure

Pretest:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient the procedure is used to monitor oxygenation of the blood.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, or anesthetics.
- Obtain a history of the patient’s respiratory and cardiovascular systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the medications the patient is taking, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that no pain is associated with the procedure. Inform the patient that the procedure is generally performed at the bedside, in the operating room during a surgical procedure, or in the office of a health care provider (HCP). Explain that the procedure lasts as long as the monitoring is needed and could be continuous.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- If a finger probe is used, instruct the patient to remove false fingernails and nail polish.
- When used in the presence of flammable gases, the equipment must be approved for that specific use.
- Instruct the patient not to smoke for 24 hr before the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

Intratest:
- Ensure that the patient has complied with pretesting instructions.
- If a finger probe is used, instruct the patient not to grip treadmill rail or bed rail tightly; doing so restricts blood flow.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Massage or apply a warm towel to the upper earlobe or finger to increase the blood flow.
- The index finger is normally used, but if the patient’s finger is too large for the probe, a smaller finger can be used.
- If the earlobe is used, make sure good contact is achieved.
- The big toe, top or bottom of the foot, or sides of the heel may be used in infants.
- Place the photodetector probe over the finger in such a way that the light beams and sensors are opposite each other. Turn the power switch to the oximeter monitor, which will display information about heart rate and peripheral capillary saturation (SaO₂).
- Remove the clip used for monitoring when the procedure is complete.

Post-test:
- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Access additional resources at davisplus.fadavis.com
Closely observe SPO₂, and report to the HCP if it decreases to 90%.
Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
Related tests include α₁-AT, anion gap, arterial/alveolar oxygen ratio, biopsy lung, blood gases, bronchoscopy, carboxyhemoglobin, chest x-ray, chloride sweat, complete blood count, complete blood count, hemoglobin, complete blood count, WBC count and differential, CT angiography, culture and smear for mycobacteria, culture bacterial sputum, culture viral, cytology sputum, ECG, gram stain, IgE, lactic acid, lung perfusion scan, lung ventilation scan, MR angiography, MR chest, osmolality, phosphorus, plethysmography, pleural fluid analysis, potassium, pulmonary function tests, sodium, and TB skin test.
Refer to the Respiratory and Cardiovascular System tables in the back of the book for related tests by body system.

---

**Pyruvate Kinase**

**SYNONYM/ACRONYM:** PK.

**SPECIMEN:** Whole blood collected in yellow-top (acid-citrate-dextrose [ACD]) tube. Specimens collected in a lavender-top (EDTA) or green-top (heparin) tube also may be acceptable in some laboratories.

**REFERENCE VALUE:** (Method: Spectrophotometry) 9 to 22 international units/g hemoglobin.

**RESULT:**
*Increased in:*
- Carriers of Duchenne’s muscular dystrophy
- Muscle disease
- Myocardial infarction

*Decreased in:*
- Hereditary pyruvate kinase deficiency:
  - Congenital nonspherocytic hemolytic anemia
- Acquired pyruvate kinase deficiency:
  - Acute leukemia
  - Aplasias
  - Other anemias

**CRITICAL VALUES:** N/A

Find and print out the full monograph at DavisPlus (davisplus.fadavis.com, keyword Van Leeuwen).
Radioactive Iodine Uptake

SYNONYM/ACRONYM: Thyroid uptake, RAIU.

AREA OF APPLICATION: Thyroid.

CONTRAST: Oral radioactive iodine.

DESCRIPTION: Radioactive iodine uptake (RAIU) is a nuclear medicine study used for evaluating thyroid function. It directly measures the ability of the thyroid gland to concentrate and retain circulating iodide for the synthesis of thyroid hormone. RAIU assists in the diagnosis of both hyperthyroidism and hypothyroidism, but it is more useful in the diagnosis of hyperthyroidism.

A very small dose of radioactive iodine-123 (I-123) or I-131 is administered orally and images are taken at specified intervals after the initial dose is administered. The radionuclide emits gamma radiation, which allows external measurement. The uptake of radionuclide in the thyroid gland is measured as the percentage of radionuclide absorbed in a specific amount of time. The iodide not used is excreted in the urine. The thyroid gland does not distinguish between radioactive and nonradioactive iodine. Uptake values are used in conjunction with measurements of circulating thyroid hormone levels to differentiate primary and secondary thyroid disease, and serial measurements are helpful in long-term management of thyroid disease and its treatment.

INDICATIONS:
- Evaluate hyperthyroidism and/or hypothyroidism
- Evaluate neck pain
- Evaluate the patient as part of a complete thyroid evaluation for symptomatic patients (e.g., swollen neck, neck pain, extreme sensitivity to heat or cold, jitters, sluggishness)
- Evaluate thyroiditis, goiter, or pituitary failure
- Monitor response to therapy for thyroid disease

RESULT:

Normal findings in:
- Variations in normal ranges of iodine uptake can occur with differences in dietary intake, geographic location, and protocols among laboratories:

<table>
<thead>
<tr>
<th>Iodine Percentage of Uptake Radionuclide</th>
</tr>
</thead>
<tbody>
<tr>
<td>2-hr absorption</td>
</tr>
<tr>
<td>6-hr absorption</td>
</tr>
<tr>
<td>24-hr absorption</td>
</tr>
</tbody>
</table>

Abnormal findings in:
- Decreased iodine intake or increased iodine excretion
- Graves’ disease
- Iodine-deficient goiter
- Hashimoto’s thyroiditis (early)
- Hyperthyroidism, increased uptake of radionuclide:
  - Rebound thyroid hormone withdrawal
  - Drugs and hormones such as barbiturates, diuretics, estrogens, lithium carbonate, phenothiazines, and thyroid-stimulating hormone
- Decreased uptake:
  - Hypothyroidism, with a response of decreased uptake of 0 to 10% over a 24-hr period
• Hypoalbuminemia
• Malabsorption
• Renal failure
• Subacute thyroiditis
• Thyrotoxicosis as a result of ectopic thyroid metastasis

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

*This procedure is contraindicated for:*

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

*Factors that may impair clear imaging:*

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Recent use of iodinated contrast medium for radiographic studies (within the last 4 wk) or nuclear medicine procedures done within the previous 24 to 48 hr
- Iodine deficiency (e.g., patients with inadequate dietary intake, patients on phenothiazine therapy), which can increase radionuclide uptake
- Certain drugs and other external sources of excess iodine, which can decrease radionuclide uptake, as follows:
  - Foods containing iodine (e.g., iodized salt)
  - Drugs such as aminosalicylic acid, antihistamines, antithyroid medications (e.g., propylthiouracil, iodothiouracil), corticosteroids, cough syrup, isoniazid, levothyroxine sodium/T₄, L-triiodothyronine, Lugol’s solution, nitrates, penicillins, potassium iodide, propylthiouracil, saturated solution of potassium iodide, sulfonamides, thiocyanate, thyroid extract, tolbutamide, and warfarin
  - Multivitamins containing minerals
- Vomiting, severe diarrhea, and gastroenteritis, which can affect absorption of the oral radionuclide dose
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

**Other considerations:**

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses thyroid function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- Ensure that this procedure is performed before all radiographic procedures using iodinated contrast medium.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient.
- Address concerns about pain related
to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a nuclear medicine department by a HCP who specializes in this procedure, with support staff, and takes approximately 15 to 30 min. Delayed images or data collection is needed 24 hr later.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

Instruct the patient to fast and restrict fluids for 8 to 12 hr before the procedure. The patient may eat 4 hr after the injection unless otherwise indicated. Protocols may vary from facility to facility.

**INTRATEST:**

- Ensure the patient has complied with dietary, fluid, and medication restrictions for 8 to 12 hr before the procedure.
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer the I-123 orally (pill form).
- Place the patient in a sitting or supine position in front of a radionuclide detector at 2, 6, and 24 hr after ingestion for uptake images.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet, as directed by the HCP.
- Advise patient to drink increased amounts of fluids for 24 hr to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 24 to 48 hr.

If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.

Instruct the patient to immediately flush the toilet, and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.

Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.

Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include ACTH, albumin, ACE, antibodies antithyroglobulin, biopsy thyroid, BUN, CT spine, copper, creatinine, cystoscopy, fecal analysis, fecal fat, FSH, gastric emptying scan, GH, LH, PTH, protein, thyroglobulin, thyroid binding inhibitory immunoglobulins, thyroid scan, TSH, TSI, thyroxine, free T₄, triiodothyronine, free T₃, US thyroid, upper GI series, and UA.

Refer to the Endocrine System table at the back of the book for tests by related body system.
**Radiofrequency Ablation, Liver**

**SYNONYM/ACRONYM:** RFA, RF ablation.

**AREA OF APPLICATION:** Liver.

**CONTRAST:** Done without contrast.

**DESCRIPTION:** One minimally invasive therapy to eliminate tumors in organs such as the liver is called radiofrequency ablation (RFA). This technique works by passing electrical current in the range of radiofrequency waves between the needle electrode and the grounding pads placed on the patient’s skin. A special needle electrode is placed in the tumor under the guidance of an imaging method such as ultrasound, computed tomography (CT) scanning, or magnetic resonance imaging (MRI). A radiofrequency current is then passed through the electrode to heat the tumor tissue near the needle tip and to ablate, or eliminate, it. The current creates heat around the electrode inside the tumor, and this heat spreads out to destroy the entire tumor, but little of the surrounding normal liver tissue. The heat from radiofrequency energy also closes up small blood vessels, thereby minimizing the risk of bleeding. Because healthy liver tissue withstands more heat than a tumor, RFA is able to destroy a tumor and a small rim of normal tissue about its edges without affecting most of the normal liver. The dead tumor cells are gradually replaced by scar tissue that shrinks over time. Some liver tumors may have failed to respond to chemotherapy, or have recurred after initial surgery, and may be treated by RFA. If there are multiple tumor nodules, they may be treated in one or more sessions. In general, RFA causes only minimal discomfort and may be done as an outpatient procedure without general anesthesia. RFA is most effective if the tumor or tumors are less than 2 in. in diameter; results are not as good when RFA is used to treat larger tumors. Similar therapy is being used to treat tumors in the kidney, pancreas, bone, thyroid, breast, adrenal gland, and lung.

**INDICATIONS:**
- Ablation of metastases to the liver
- Ablation of primary liver tumors, with hepatocellular carcinoma
- Therapy for multiple small liver tumors that are too spread out to remove surgically
- Therapy for recurrent liver tumors
- Therapy for tumors that are less than 2 in. in diameter
- Therapy for tumors that have failed to respond to chemotherapy
- Therapy for tumors that have recurred after initial surgery

**Risks:**
- May cause brief or long-lasting shoulder pain.
- May cause inflammation of the gallbladder.
• May cause damage to the bile ducts with resulting biliary obstruction.
• May cause thermal damage to the bowel.
• The patient may experience flu-like symptoms that appear 3 to 5 days after the procedure and last for approximately 5 days.
• The patient may experience bleeding. If bleeding is severe, surgery may be needed.

RESULT:

Normal findings in:
• Decrease in tumor size
• Normal size, position, contour, and texture of the liver

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with bleeding disorders
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
• Metallic objects (e.g., jewelry, rings, surgery clips) within the examination field, which may inhibit organ visualization and cause unclear images
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
• Failure to follow dietary restrictions and other pretesting preparations before the procedure may cause the procedure to be canceled or repeated.
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

PRETEST:

Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
Inform the patient that the procedure assesses liver function.
Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, and anesthetics.
Obtain a history of the patient’s hepatobiliary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
Note any recent procedures that can interfere with test results, including barium examinations.
Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
Review the procedure with the patient. Address concerns about pain related to the procedure and explain that a sedative and/or analgesia will be administered to promote relaxation and...
reduce discomfort prior to the needle electrode insertion. Explain to the patient that any discomfort with the needle electrode will be minimized with local anesthetics and systemic analgesics. Inform the patient that the procedure is performed in the radiology department by a HCP, with support staff, and takes approximately 30 to 90 min. Explain that an IV line may be inserted to allow infusion of IV fluids, or sedatives. Usually normal saline is infused.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.

This procedure may be terminated if chest pain or severe cardiac arrhythmias occur.

Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure.

Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

Ensure that the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations.

Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.

Have emergency equipment readily available.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.

Instruct the patient to void and change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Record baseline vital signs and assess neurological status. Protocols may vary from facility to facility.

Observe standard precautions, and follow the general guidelines in Appendix A.

Establish an IV fluid line for the injection of emergency drugs and of sedatives.

Administer an anxiolytic agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.

Place the patient in the supine position on an exam table. Cleanse the selected area, and cover with a sterile drape.

A local anesthetic is injected at the site, and a needle electrode is inserted under ultrasound, CT, or MRI guidance.

A radiofrequency current is passed through the needle electrode, and the tumor is ablated.

Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.

The needle electrode is removed, and a pressure dressing is applied over the puncture site.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

POST-TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 6 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Observe the needle electrode insertion site for bleeding, inflammation, or hematoma formation.
Instruct the patient to maintain bed rest for 4 to 6 hr after the procedure or as ordered.

Advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

Instruct the patient in the care and assessment of the site. Observe for bleeding, hematoma formation, bile leakage, and inflammation. Note any pleuritic pain, persistent right shoulder pain, or abdominal pain.

Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.

Recognize anxiety related to test results, and be supportive of impaired activity related to physical activity. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include angiography abdomen, AST, biopsy liver, CT liver, MRI abdomen, and US liver and biliary system.
- Refer to the Hepatobiliary System table at the back of the book for related tests by body system.

---

**Radiography, Bone**

**SYNONYM/ACRONYM:** Bone x-rays, hand x-rays, foot x-rays, wrist x-rays, arm x-rays.

**AREA OF APPLICATION:** Skeleton.

**CONTRAST:** None.

**DESCRIPTION:** Skeletal x-rays are used to evaluate extremity pain or discomfort due to trauma, bone abnormalities, or fluid within a joint. Serial skeletal x-rays are used to evaluate growth pattern. Radiation emitted from the x-ray machine passes through the patient onto a photographic plate or x-ray film. X-rays pass through air freely and are mostly absorbed by the photographic media. Bones and tissues absorb the x-rays in varying degrees, thereby causing white and shades of gray on the x-ray recording media: Bones are very dense and therefore absorb most of the x-ray and appear white; organs are denser than air but not as dense as bone, so they appear in shades of gray. All metals absorb x-rays.
INDICATIONS:
• Assist in detecting bone fracture, dislocation, deformity, and degeneration
• Evaluate for child abuse
• Evaluate growth pattern
• Identify abnormalities of bones, joints, and surrounding tissues
• Monitor fracture healing process

RESULT:
Normal findings in:
• Infants and children: Thin plate of cartilage, known as growth plate or epiphyseal plate, between the shaft and both ends
• Adolescents and adults: By age 17, calcification of cartilage plate; no evidence of fracture, congenital abnormalities, tumors, or infection

Abnormal findings in:
• Arthritis
• Bone degeneration
• Bone spurs
• Foreign bodies
• Fracture
• Genetic disturbance (achondroplasia, dysplasia, dyostosis)
• Hormonal disturbance
• Infection, including osteomyelitis
• Injury
• Joint dislocation or effusion
• Nutritional or metabolic disturbances
• Osteoporosis or osteopenia
• Soft-tissue abnormalities
• Tumor or neoplastic disease (osteogenic sarcoma, Paget’s disease, myeloma)

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
• Retained barium from a previous radiological procedure
• Metallic objects (e.g., jewelry, body rings) within the examination field which may inhibit organ visualization and can produce unclear images
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the exam room with the patient should wear a protective lead apron or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses bone structure of the area examined.
Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.

Obtain a history of the patient’s musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Explain that numerous x-rays may be taken depending on the bones or joint affected. Address concerns about pain and explain that some pain may be experienced during the test, or there may be moments of discomfort. Inform the patient that the procedure is performed in the radiology department by a HCP, with support staff, and takes approximately 10 to 30 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient to inhale deeply and hold his or her breath while the image is taken. Warn the patient that the extremity’s position during the procedure may be uncomfortable, but ask the patient to hold very still during the procedure because movement will produce unclear images.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

**POST-TEST:**

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Recognize anxiety related to test results, and be supportive of impaired activity related to the perceived loss of daily function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Explain the importance of adhering to the therapy regimen. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include antibodies anticyclic citrullinated peptide, ANA, arthrogram, arthroscopy, biopsy bone, BMD, bone scan, CRP, calcium, collagen cross-linked telopeptides, CT spine, ESR, MRI musculoskeletal, osteocalcin, phosphorus, synovial fluid analysis, RF, vitamin D, and WBC scan.

Refer to the Musculoskeletal System table at the back of the book for related tests by body system.
Red Blood Cell Cholinesterase

SYNONYM/ACRONYM: acetylcholinesterase (AChE), erythrocyte cholinesterase, true cholinesterase.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

REFERENCE VALUE: (Method: Spectrophotometry, kinetic)

<table>
<thead>
<tr>
<th>Test</th>
<th>Conventional Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>RBC cholinesterase</td>
<td>5300–10,000 international units/L</td>
</tr>
</tbody>
</table>

DESCRIPTION: There are two types of cholinesterase enzyme: *acetylcholinesterase (AChE)*, which is found in red blood cells (RBCs), lung, and brain (nerve) tissue; and *cholinesterase*, which is mainly found in the plasma, liver, and heart. RBC AChE is highly specific for acetylcholine. Cholinesterase has broader esterolytic activity and is referred to as “pseudocholinesterase.” Pseudocholinesterase is the test used to indicate succinylcholine sensitivity (see monograph titled “Pseudocholinesterase and Dibucaine Number”). RBC cholinesterase is used to assist in the diagnosis of chronic carbamate or organophosphate insecticide (e.g., parathion, malathion) toxicity. Organophosphate pesticides bind irreversibly with cholinesterase, inhibiting normal enzyme activity. Carbamate insecticides bind reversibly. Serum or plasma pseudocholinesterase is used more frequently to measure acute pesticide toxicity.

Patients with inherited cholinesterase deficiency are at risk during anesthesia if succinylcholine is administered as an anesthetic. Succinylcholine, a short-acting muscle relaxant, is a reversible inhibitor of acetylcholinesterase and is hydrolyzed by cholinesterase. Succinylcholine-sensitive patients may be unable to metabolize the anesthetic quickly, resulting in prolonged or unrecoverable apnea. This test, along with the pseudocholinesterase test, is also used to identify individuals with atypical forms of the enzyme cholinesterase. The prevalence of succinylcholate sensitivity is 1 in 1500 patients. Widespread preoperative screening is not routinely performed.

INDICATIONS:
- Monitor cumulative exposure to organic phosphate insecticides
- Verify suspected exposure to organic phosphate insecticides

RESULT:
- Increased in: Sickle cell anemia (*Increased in hemolytic anemias as it is released from the hemolyzed RBCs*)
**Decreased in:**
- Insecticide exposure (*Organic phosphate insecticides inhibit AChE activity*)
- Late pregnancy (*Related to anemia of pregnancy*)
- Paroxysmal nocturnal hemoglobinuria (*Related to lack of RBC production by bone marrow*)
- Relapse of megaloblastic anemia (*Related to underproduction of normal RBCs containing AChE*)

**Critical Values:** N/A

**Interfering Factors:**
- Drugs and substances that may increase RBC cholinesterase levels include echothiophate, parathion, and antiepileptic drugs such as carbamazepine, phenobarbital, phenytoin, and valproic acid.
- Improper anticoagulant; fluoride interferes with the measurement and causes a falsely decreased value.

**Nursing Implications and Procedure**

**Pretest:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to identify pesticide poisoning.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex. Particularly important to report is exposure to pesticides causing symptoms including blurred vision, muscle weakness, nausea, vomiting, headaches, pulmonary edema, salivation, sweating, or convulsions.
- Obtain a history of exposure to occupational hazards and medication regimen.
- Obtain a history of the patient’s hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**Intratest:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**Post-test:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
- Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a...
change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include biopsy bone marrow, complete blood count, complete blood count, RBC indices, complete blood count, RBC morphology, Ham’s test, pseudo-cholinesterase, sickle cell screen, and vitamin B₁₂.
- Refer to the Hematopoietic System table at the back of the book for related tests by body system.

---

**Refraction**

**SYNONYM/ACRONYM:** N/A.

**AREA OF APPLICATION:** Eyes.

**CONTRAST:** N/A.

**DESCRIPTION:** This noninvasive procedure tests the visual acuity (VA) of the eyes and determines abnormalities or refractive errors that need correction. Refractions are performed using a combination of different pieces of equipment. Refractive error can be quickly and accurately measured using computerized automatic refractors or manually with a viewing system consisting of an entire set of trial lenses mounted on a circular wheel (phoropter). A projector may also be used to display test letters and characters for use in assessing VA. If the VA is less than 20/20 the pinhole test may be used to quickly assess the best corrected vision. Refractive errors of the peripheral cornea and lens can be reduced or eliminated by having the patient look through a pinhole at the vision test. Patients with cataracts or visual field defects will not show improved results using the pinhole test. The retinoscope is probably the most valuable instrument that can be used to objectively assess VA. It is also the only objective means of assessing refractive error in pediatric patients and patients who are unable to cooperate with other techniques of assessing refractive error due to illiteracy, senility, or inability to speak the same language as the examiner. Visual defects identified through refraction, such as hyperopia (farsightedness), in which the point of focus lies behind the retina; myopia (nearsightedness), in which the point of focus lies in front of the retina; and astigmatism, in which the refraction is unequal in different curvatures of the eyeball, can be corrected by glasses, contact lenses, or refractive surgery.
**INDICATIONS:**
- Determine if an optical defect is present and if light rays entering the eye focus correctly on the retina.
- Determine the refractive error prior to refractive surgery—e.g., radial keratotomy (RK), photorefractive keratotomy (PRK), laser assisted in situ keratomileusis (LASIK), intracorneal rings (Intacs), limbal relaxing incisions (LRI), implantable contact lens (phakic IOL), clear lens replacement—being performed.
- Determine the type of corrective lenses needed for refractive errors, for example, biconvex or plus lenses for hyperopia, biconcave or minus lenses for myopia, compensatory lenses for astigmatism.
- Diagnose refractive errors in vision.

**RESULT:**

**Visual Acuity Scale**

</table>

VA can be expressed fractionally in feet, fractionally in meters, or as a decimal where perfect vision of 20/20 feet or 6/6 meters is equal to 1. A patient who cannot achieve best corrected VA of 20/200 or above in his or her better eye is considered legally blind in the U.S. Comparing the fraction in feet or meters to the decimal helps demonstrate that “less than” 20/20 is “worse” vision while acuity “greater than” 20/20 is “better.”

**Normal findings in:**
- Normal visual acuity; greater than 20/30 (with corrective lenses if appropriate).

**Abnormal findings in:**
- Corrected visual acuity of 20/40 or less.
- Refractive errors such as astigmatism, hyperopia, and myopia.

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

**This procedure is contraindicated for:**
- Patients with narrow-angle glaucoma if pupil dilation is performed, as dilation can initiate a severe and sight-threatening open-angle attack.
- Patients with allergies to mydriatics if pupil dilation using mydriatics is performed.

**Factors that may impair clear imaging:**
- Improper pupil dilation may prevent adequate examination for refractive error.
- Inability of the patient to cooperate and remain still during the procedure because of age, significant pain, or mental status may interfere with the test results.
- Failure to follow medication restrictions before the procedure may cause the procedure to be canceled or repeated.

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure evaluates visual acuity.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially mydriatics if dilation is to be performed.

Access additional resources at davisplus.fadavis.com
Obtain a history of the patient’s known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.

Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Instruct the patient to remove contact lenses or glasses, as appropriate.

Instruct the patient regarding the importance of keeping the eyes open for the test.

Review the procedure with the patient.

Address concerns about pain and explain that mydriatics, if used, may cause blurred vision and sensitivity to light. There may also be a brief stinging sensation when the drop is put in the eye. Inform the patient that a health care provider (HCP) performs the test, in a quiet, darkened room, and that to evaluate both eyes, the test can take up 30 min (including time for the pupils to dilate before the test is actually performed).

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food or fluid restrictions, unless by medical direction.

The patient should withhold eye medications (particularly mydriatic eye drops if the patient has glaucoma) for at least 1 day prior to the test.

Ensure that the patient understands that he or she must refrain from driving until the pupils return to normal (about 4 hours) after the test and has made arrangements to have someone else be responsible for transportation after the test.

**INTRA-TEST:**

Ensure that the patient has complied with medication restrictions and pretesting preparations; assure that eye medications, especially mydriatics, have been restricted for at least 1 day prior to the procedure.

Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.

If dilation is to be performed, administer the ordered mydriatic to each eye and repeat in 5 to 15 min. Drops are placed in the eye with the patient looking up and the solution directed at the six o’clock position of the sclera (white of the eye) near the limbus (grey, semi-transparent area of the eyeball where the cornea and sclera meet). The dropper bottle should not touch the eyelashes.

Ask the patient to place the chin in the chin rest and gently press the forehead against the support bar. The examiner will sit about 2 ft away at eye level with the patient. The retinascope light is held in front of the eyes and directed through the pupil. Each eye is also examined for the characteristics of the red reflex, the reflection of the light from the retinascope, which normally moves in the same direction as the light.

Request that the patient look straight ahead while the eyes are examined with the instrument and while different lenses are tried to provide the best corrective lenses to be prescribed. When optimal VA is obtained with the trial lenses in each eye, a prescription for corrective lenses is written.

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual medications, as directed by the HCP.

Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss, anticipated loss of driving privileges, or the possibility of requiring corrective lenses (self-image). Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Provide contact information, if desired, for a general patient education web
site on the topic of eye care (e.g., www.allaboutvision.com).

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that visual acuity and responses to light may change. Suggest that the patient wear dark glasses after the test until the pupils return to normal size.
- Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**Related Monographs:**
- Related tests include color perception test, intraocular muscle function, intraocular pressure, Schirmer tear test, and slit-lamp biomicroscopy.
- Refer to the Ocular System table at the back of the book for related tests by body system.

---

**Renin**

**Synonym/ACRONYM:** Plasma renin activity (PRA).

**SPECIMEN:** Plasma (3 mL) collected in a lavender-top (EDTA) tube.

**Reference Value:** (Method: Radioimmunoassay)

**Description:** Renin is an enzyme that activates the renin-angiotensin system. It is released into the renal veins by the juxtaglomerular apparatus in response to sodium depletion and hypovolemia. Renin converts angiotensinogen to angiotensin I. Angiotensin I is converted to angiotensin II, the biologically active form. Angiotensin II is a powerful vasoconstrictor that...
stimulates aldosterone production in the adrenal cortex. Angiotensin II and aldosterone increase blood pressure. Excessive amounts of angiotensin II cause renal hypertension. The renin assay screens for essential, renal, or renovascular hypertension. Plasma renin is expressed as the rate of angiotensin I formation per unit of time. The random collection of specimens without prior dietary preparations does not provide clinically significant information. Values should also be evaluated along with simultaneously collected aldosterone levels (see monographs titled “Aldosterone” and “Angiotensin-Converting Enzyme”).

**INDICATIONS:**
- Assist in the identification of primary hyperaldosteronism resulting from aldosterone-secreting adrenal adenoma
- Assist in monitoring patients on mineralocorticoid therapy
- Assist in the screening of the origin of essential, renal, or renovascular hypertension

**RESULT:**

**Increased in:**
- Addison’s disease (*Related to hyponatremia, which stimulates production of renin*)
- Bartter’s syndrome (*Hereditary defect in Loop of Henle that affects sodium resorption; hyponatremia stimulates renin production*)
- Cirrhosis (*Fluid buildup dilutes sodium concentration; hyponatremia is a strong stimulus for production of renin*)
- Congestive heart failure (*Fluid buildup dilutes sodium concentration; hyponatremia is a strong stimulus for production of renin*)
- Gastointestinal disorders with electrolyte loss (*Hyponatremia stimulates production of renin*)
- Hepatitis (*Fluid buildup dilutes sodium concentration; hyponatremia is a strong stimulus for production of renin*)
- Hypokalemia (*Decreased potassium levels stimulate renin production*)
- Malignant hypertension (*Related to secondary hyperaldosteronism that constricts the blood vessels and results in hypertension*)
- Nephritis (*The kidneys can produce renin in response to inflammation or disease*)
- Nephropathies with sodium or potassium wasting (*Hyponatremia stimulates production of renin*)
- Pheochromocytoma (*Related to renin production in response to hypertension*)
- Pregnancy (*Related to retention of fluid and hyponatremia that stimulates renin production; normal pregnancy is associated with changes in the balance between renin and angiotensin*)
- Renin-producing renal tumors
- Renovascular hypertension (*Decreased renal blood flow stimulates release of renin*)

**Decreased in:**
- Cushing’s syndrome (*Excessive production of glucocorticoids increase sodium levels and decrease potassium levels, which inhibits renin production*)
- Primary hyperaldosteronism (*Aldosterone secreting adrenal tumor; aldosterone inhibits renin production*)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase renin levels include albuterol, amiloride, azosemide, benazepril,
bendroflumethiazide, captopril, chlorthalidone, cilazapril, cromakalim, desmopressin, diazoxide, dihydroalazine, doxazosin, enalapril, endralazine, felodipine, fenoldopam, fosinopril, furosemide, hydralazine, hydrochlorothiazide, laxatives, lisinopril, lithium, methyclothiazide, metolazone, muzolimine, nicardipine, nifedipine, opiates, oral contraceptives, perindopril, ramipril, spironolactone, triamterene, and xipamide.

- Drugs and substances that may decrease renin levels include acetylsalicylic acid, angiotensin, angiotensin II, atenolol, bopindolol, bucindolol, carbenoxolone, carvedilol, clonidine, cyclosporin A, dexfenfluramine, glycyrrhiza, ibuprofen, indomethacin, levodopa, metoprolol, naproxen, nicardipine, nonsteroidal anti-inflammatory drugs, oral contraceptives, oxprenolol, propranolol, sulindac, and vasopressin.

- Upright body posture, stress, and strenuous exercise can increase renin levels.

- Recent radioactive scans or radiation can interfere with test results when radioimmunoassay is the test method.

- Diet can significantly affect results (e.g., low-sodium diets stimulate the release of renin).

- Hyperkalemia, acute increase in blood pressure, and increased blood volume may suppress renin secretion.

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**Inform the patient that the test is used to evaluate hypertension.**

**Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.**

**Obtain a history of the patient’s endocrine and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.**

**Note any recent procedures that can interfere with test results.**

**Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.**

**Review the procedure with the patient. Inform the patient or family member that the position required (supine or upright) must be maintained for 2 hr before specimen collection. Inform the patient that multiple specimens may be required. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.**

**Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.**

**The patient should be on a normal sodium diet (1 to 2 g sodium per day) for 2 to 4 wk before the test. Protocols may vary from facility to facility.**

**By medical direction, the patient should avoid diuretics, antihypertensive drugs, herbals, cyclic progestogens, and estrogens for 2 to 4 wk before the test.**

**Prepare an ice slurry in a cup or plastic bag to have ready for immediate transport of the specimen to the laboratory.**

**Ensure that the patient has complied with diet and medication restrictions and pretesting dietary preparations; assure that specific medications have been restricted for at least 2 to 4 wk prior to the procedure.**

**If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.**

**Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.**

---

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Specify patient position (upright or supine) and exact source of specimen (peripheral vs. arterial). Perform a venipuncture after the patient has been in the upright (sitting or standing) position for 2 hr. If a supine specimen is requested on an inpatient, the specimen should be collected early in the morning before the patient rises.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

The sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag. Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Instruct the patient to resume usual medications, as directed by the HCP.

Nutritional considerations: Instruct the patient to notify the requesting HCP of any signs and symptoms of dehydration or fluid overload related to abnormal renin levels or compromised sodium regulatory mechanisms. Fluid loss or dehydration is signaled by the thirst response. Decreased skin turgor, dry mouth, and multiple longitudinal furrows in the tongue are symptoms of dehydration. Fluid overload may be signaled by a loss of appetite and nausea. Excessive fluid also causes pitting edema: When firm pressure is placed on the skin over a bone (e.g., the ankle), the indentation will remain after 5 sec.

Nutritional considerations: Educate patients of the importance of proper water balance. There is no recommended daily allowance (RDA) for water. Adults need 1 mL/kcal per day; infants need more because their basal metabolic heat production is much higher. In buildings with hard water, untreated tap water contains minerals such as calcium, magnesium, and iron. Water-softening systems replace these minerals with sodium, and therefore patients on a low-sodium diet should avoid drinking treated tap water and drink bottled water instead.

Nutritional considerations: Renin levels affect the regulation of fluid balance and electrolytes. If appropriate, educate patients with low sodium levels that the major source of dietary sodium is found in table salt. Many foods, such as milk and other dairy products, are also good sources of dietary sodium. Most other dietary sodium is available through the consumption of processed foods. Patients on low-sodium diets should be advised to avoid beverages such as colas, ginger ale, sports drinks, lemon-lime sodas, and root beer. Many over-the-counter medications, including antacids, laxatives, analgesics, sedatives, and antitussives, contain significant amounts of sodium. The best advice is to emphasize the importance of reading all food, beverage, and medicine labels. In 1989, the Subcommittee on the 10th Edition of the RDA established 500 mg/d as the recommended maximum daily intake for dietary intake of sodium. The requesting HCP or nutritionist should be consulted before the patient on a low-sodium diet begins using salt substitutes. There are no RDAs established for potassium, but the estimated minimum intake for adults is 200 mEq/d. Potassium is present in all plant and animal cells, making dietary replacement fairly simple to achieve.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation...
Renogram

SYNONYM/ACRONYM: Renocystography, renocystogram, radioactive renogram, renal scintigraphy.

AREA OF APPLICATION: Kidneys.

CONTRAST: IV radioactive material.

DESCRIPTION: A renogram is a nuclear medicine study performed to assist in diagnosing renal disorders, such as abnormal blood flow, collecting-system defects, and excretion dysfunction. Because renography uses no iodinated contrast medium, it is safe to use in patients who have iodine allergies or compromised renal function.

After IV administration of the radioisotope, information about the structures of the kidneys is obtained. The radioactive material is detected by a gamma camera, which can detect the gamma rays emitted by the radionuclide in the kidney. Renography simultaneously tracks the rate at which the radionuclide flows into (vascular phase), through (tubular phase), and out of (excretory phase) the kidneys. The times are plotted on a graph and compared to normal parameters of organ function.

Differential estimates of left and right kidney contributions to glomerular filtration rate and effective renal plasma flow can be calculated. With the use of diuretic stimulation during the excretory phase, it is possible to differentiate between anatomic obstruction and nonobstructive residual dilation from previous hydronephrosis. All information obtained is stored in a computer to be used for further interpretation and computations. Renal function can be monitored by serially repeating this test and comparing results.

INDICATIONS:
- Aid in the diagnosis of renal artery embolism or renal infarction causing obstruction
- Aid in the diagnosis of renal artery stenosis resulting from renal dysplasia or atherosclerosis and

Related tests include ACTH, ALT, aldosterone, ACE, AST, ANP, BNP, bilirubin, biopsy kidney, BUN, calcium, chloride, cortisol, creatinine, DHEAS, fecal fat, GGT, glucose, GTT, magnesium, metanephrines, potassium, protein total and fractions, renogram, sodium, UA, and VMA.

Refer to the Endocrine and Genitourinary System tables at the back of the book for related tests by body system.
causing arterial hypertension and reduced glomerular filtration rate

- Aid in the diagnosis of renal vein thrombosis resulting from dehydration in infants or obstruction of blood flow in the presence of renal tumors in adults
- Detect renal infectious or inflammatory diseases, such as acute or chronic pyelonephritis, renal abscess, or nephritis
- Determine the presence and effects of renal trauma, such as arterial injury, renal contusion, hematoma, rupture, arteriovenous fistula, or urinary extravasation
- Determine the presence, location, and cause of obstructive uropathy, such as calculi, neoplasm, congenital disorders, scarring, or inflammation
- Evaluate acute and chronic renal failure
- Evaluate chronic urinary tract infections, especially in children
- Evaluate kidney transplant for acute or chronic rejection
- Evaluate obstruction caused by stones or tumor

RESULT:

Normal findings in:
- Normal shape, size, position, symmetry, vasculature, perfusion, and function of the kidneys
- Radionuclide material circulates bilaterally, symmetrically, and without interruption through the renal parenchyma, ureters, and urinary bladder, with 50% of the radionuclide excreted within the first 10 min

Abnormal findings in:
- Acute tubular necrosis
- Congenital anomalies (e.g., absence of a kidney)
- Decreased renal function
- Diminished blood supply
- Infection or inflammation (pyelonephritis, glomerulonephritis)
- Masses
- Obstructive uropathy
- Renal failure, infarction, cyst, or abscess
- Renal vascular disease, including renal artery stenosis or renal vein thrombosis
- Trauma

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Serum creatinine levels greater than or equal to 3 mg/dL (depending on the radionuclide used), which can decrease renal perfusion
- Other nuclear medicine studies done within the previous 24 to 48 hr
- Medications such as antihypertensives, angiotensin-converting enzyme (ACE) inhibitors, and β-blockers taken within 24 hr of the test
- Dehydration, which can accentuate abnormalities; or overhydration, which can mask abnormalities
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization

Other considerations:
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from
frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

- Inaccurate timing of imaging after the radionuclide injection can affect the results.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the renal system.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
- Obtain a history of the patient’s genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Reassure the patient that radioactive material poses minimal radioactive hazard because of its short half-life and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department by a HCP and usually takes approximately 60 to 90 min, and that delayed images are needed 2 to 24 hr later. The patient may leave the department and return later to undergo delayed imaging.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- Inform the patient that he or she will be asked to drink several glasses of fluid before the study for hydration, unless the patient has a restricted fluid intake for other reasons.
- There are no food or medication restrictions, unless by medical direction.

**INTRATEST:**
- Ensure that the patient has removed external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Administer sedative to a child or to an uncooperative adult, as ordered.
- Place the patient in a supine position on a flat table with foam wedges to help maintain position and immobilization.
- The radionuclide is administered IV, and the kidney area is scanned immediately with images taken every minute for 30 min.
- During the flow and static imaging, the diuretic furosemide (Lasix) or ACE inhibitor (captopril) can be administered IV and images obtained.
- Urine and blood laboratory studies are done after the renogram to correlate findings before diagnosis.
- If a study for vesicoureteral reflux is done, the patient is asked to void, and a catheter is inserted into the bladder. The radionuclide is instilled into the bladder, and multiple images are obtained during bladder filling. The patient is then requested to void, with the catheter in place or after catheter removal, depending on department policy. Imaging is continued during and after voiding. Reflux is determined by
calculating the urine volume and counts obtained by imaging.

Gloves should be worn during the radionuclide administration and while handling the patient’s urine.

POST-TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Unless contraindicated, advise patient to drink increased amounts of fluids for 24 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.

Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.

Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash ungloved hands after the gloves are removed.

Observe the needle site for bleeding, hematoma formation, and inflammation. Instruct the patient in the care and assessment of the injection site.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical importance of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include angiography renal, antibodies anti-glomerular basement membrane, biopsy kidney, bladder cancer markers, BUN, calculus kidney stone panel, C4, CT abdomen, CT pelvis, CT renal, creatinine, creatinine clearance, cystoscopy, IVP, KUB studies, MRA, MRI abdomen, retrograde ureteropyelography, strep group A, US kidney, and UA.

Refer to the Genitourinary System table at the back of the book for related tests by body system.

Reticulocyte Count

SYNONYM/ACRONYM: Retic count.

SPECIMEN: Whole blood (1 mL) collected in lavender-top (EDTA) tube.

REFERENCE VALUE: (Method: Microscopic examination of specially stained peripheral blood smear or automated analyzer)

<table>
<thead>
<tr>
<th>Age</th>
<th>Total Erythrocyte Count*</th>
</tr>
</thead>
<tbody>
<tr>
<td>Newborn</td>
<td>3%–7%</td>
</tr>
<tr>
<td>1–12 mo</td>
<td>0.2%–2.8%</td>
</tr>
<tr>
<td>Adult</td>
<td>1.5%–2.5%</td>
</tr>
</tbody>
</table>

*Values are expressed as percentage of the red blood cell count.
DESCRIPTION: Normally, as it matures, the red blood cell (RBC) loses its nucleus. The remaining ribonucleic acid (RNA) will produce a characteristic color when special stains are used, making these cells easy to identify and enumerate. The presence of reticulocytes is an indication of the level of erythropoietic activity in the bone marrow. In abnormal conditions, reticulocytes are prematurely released into circulation. (See monographs titled “Complete Blood Count, RBC Count” and “Complete Blood Count, RBC Morphology and Inclusions.”)

INDICATIONS:
- Evaluate erythropoietic activity
- Monitor response to therapy for anemias

RESULT:
The reticulocyte production index (RPI) is a good estimate of RBC production. The calculation corrects the count for anemia and for the premature release of reticulocytes into the peripheral blood during periods of hemolysis or significant bleeding. The RPI also takes the maturation time of large polychromatophilic cells or nucleated RBCs seen on the peripheral smear into consideration:

\[
\text{RPI} = \frac{\% \text{ reticulocytes} \times (\text{patient hematocrit (Hct)}/\text{normal Hct}) \times (1/\text{maturation time})}{\text{(1/maturation time)}}
\]

As the formula shows, the RPI is inversely proportional to Hct, as follows:

<table>

</tbody>
</table>

Increased in:
- Conditions that result in excessive RBC loss or destruction stimulate a compensatory bone marrow response by increasing production of rbcs.
  - Blood loss
  - Hemolytic anemias
  - Iron-deficiency anemia
  - Megaloblastic anemia

Decreased in:
- Alcoholism (Decreased production related to nutritional deficit)
- Anemia of chronic disease
- Aplastic anemia (Related to overall lack of RBC)
- Bone marrow replacement (New marrow fails to produce rbcs until it engrafts)
- Endocrine disease (Hypometabolism related to hypothyroidism is reflected by decreased bone marrow activity)
- RBC aplasia (Related to overall lack of RBC)
- Renal disease (Diseased kidneys cannot produce erythropoietin which stimulates the bone marrow to produce rbcs)
- Sideroblastic anemia (Rbcs are produced but are abnormal in that they cannot incorporate iron into hemoglobin, resulting in anemia)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs that may increase reticulocyte counts include acetanilid, acetylsalicylic acid, amyl nitrate, antimalarials, antipyretics, antipyrine, arsenicals, corticotropin, dimercaprol, furaltadone, furazolidone, levodopa, methyldopa, nitrofurans, penicillin, procainamide, and sulfones.
- Drugs that may decrease reticulocyte counts include azathioprine, dactinomycin, hydroxyurea, methotrexate, and zidovudine.
• Reticulocyte count may be falsely increased by the presence of RBC inclusions (Howell-Jolly bodies, Heinz bodies, and Pappenheimer bodies) that stain with methylene blue.
• Reticulocyte count may be falsely decreased after a recent blood transfusion, as a result of the dilutional effect.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➧ Inform the patient that the test is used to assess erythropoietic activity and monitor antianemic therapy.
➧ Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
➧ Obtain a history of the patient’s hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
➧ Note any recent procedures that can interfere with test results.
➧ Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
➧ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
➧ Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
➧ There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
➧ If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

POST-TEST:
➧ A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
➧ Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
➧ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
➧ Related tests include biopsy bone marrow, complement, complete blood count, complete blood count, hemoglobin, complete blood count, RBC count, complete blood count, RBC indices, complete blood count, RBC morphology, Coomb’s antiglobulin direct and indirect, erythropoietin, iron/TIBC, ferritin, folate, G6PD, Ham’s test, Hgb electrophoresis, lead, osmotic fragility, PK, sickle cell screen, and vitamin B12.
➧ Refer to the Hematopoietic System table at the back of the book for related tests by body system.
**Retrograde Ureteropyelography**

**SYNONYM/ACRONYM:** Retrograde.

**AREA OF APPLICATION:** Renal calyces, ureter.

**CONTRAST:** Radiopaque iodine-based contrast medium.

**DESCRIPTION:** Retrograde ureteropyelography uses a contrast medium introduced through a ureteral catheter during a cystography and radiographic visualization to view the renal collecting system (calyces, renal pelvis, and urethra). During a cystoscopic examination, a catheter is advanced through the ureters and into the kidney; contrast medium is injected through the catheter into the kidney. This procedure is primarily used in patients who are known to be hypersensitive to IV injected iodine-based contrast medium and when excretory ureterography does not adequately reveal the renal collecting system. The incidence of allergic reaction to the contrast medium is reduced because there is less systemic absorption of the contrast medium when injected into the kidney than when injected IV. Retrograde ureteropyelography sometimes provides more information about the anatomy of the different parts of the collecting system than can be obtained by excretory ureteropyelography. The procedure is not hampered by impaired renal function, but it carries the risk of urinary tract infection and sepsis.

**INDICATIONS:**
- Evaluate the effects of urinary system trauma
- Evaluate known or suspected ureteral obstruction
- Evaluate placement of a ureteral stent or catheter
- Evaluate the presence of calculi in the kidneys, ureters, or bladder
- Evaluate the renal collecting system when excretory urography is unsuccessful
- Evaluate space-occupying lesions or congenital anomalies of the urinary system
- Evaluate the structure and integrity of the renal collecting system

**RESULT:**

**Normal findings in:**
- Normal outline and opacification of renal pelvis and calyces
- Normal size and uniform filling of the ureters
- Symmetrical and bilateral outline of structures

**Abnormal findings in:**
- Congenital renal or urinary tract abnormalities
- Hydronephrosis
- Neoplasms
- Obstruction as a result of tumor, blood clot, stricture, or calculi
- Obstruction of ureteropelvic junction
- Perinephric abscess
- Perinephric inflammation or suppuration
- Polycystic kidney disease
• Prostatic enlargement
• Tumor of the kidneys or the collecting system

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
• Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
• Patients who are in renal failure.
• Patients with renal insufficiency, indicated by a blood urea nitrogen value greater than 40 mg/dL, because contrast medium can complicate kidney function.
• Young patients (17 y.o. and younger), unless the benefits of the x-ray diagnosis outweigh the risks of exposure to high levels of radiation.
• Patients with multiple myeloma, who may experience decreased kidney function subsequent to administration of contrast medium.

Factors that may impair clear imaging:
• Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study.
• Retained barium from a previous radiological procedure.
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations:
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
• Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses the renal collecting system.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
• Obtain a history of the patient’s genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Note any recent procedures that can interfere with test results, including examinations using barium.
Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.

Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, or there may be moments of discomfort. Inform the patient that the procedure is performed in a special department, usually in a radiology or vascular suite, by a HCP, with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. Inform the patient that he or she may receive a laxative the night before the test and an enema or a cathartic the morning of the test, as ordered.

Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives. Usually normal saline is infused.

Inform the patient that if a local anesthetic is used, the patient may feel (1) some pressure in the kidney area as the catheter is introduced and contrast medium injected, and (2) the urgency to void.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.

Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility.

This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

Ensure that the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.

Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Record baseline vital signs and assess neurological status. Protocols may vary from facility to facility.

Observe standard precautions, and follow the general guidelines in Appendix A.

Establish an IV fluid line for the injection of emergency drugs and of sedatives.

Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.

Place patient supine on the table in the lithotomy position.

A kidney, ureter, and bladder (KUB) or plain image is taken to ensure that no barium or stool will obscure visualization of the urinary system. The patient may be asked to hold his or her breath to facilitate visualization.

The patient is given a local anesthetic, and a cystoscopic examination is performed and the bladder is inspected.
A catheter is inserted, and the renal pelvis is emptied by gravity. Contrast medium is introduced into the catheter. Inform the patient that the contrast medium may cause a temporary flushing of the face, a feeling of warmth, or nausea.

X-ray images are made and the results processed. Inform the patient that additional images may be necessary to visualize the area in question.

Additional contrast medium is injected through the catheter to outline the ureters as the catheter is withdrawn. The catheter may be kept in place and attached to a gravity drainage unit until urinary flow has returned or is corrected.

Additional x-ray images are taken 10 to 15 min after the catheter is removed to evaluate retention of the contrast medium, indicating urinary stasis.

**POST-TEST:**

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed.
- Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.

**Monitor for signs of sepsis and severe pain in the kidney area.**

- Maintain the patient on adequate hydration after the procedure. Encourage the patient to drink lots of fluids to prevent stasis and to prevent the buildup of bacteria.

**Nutritional considerations:** A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.

- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include angiography renal, BUN, calculus kidney stone panel, CT abdomen, creatinine, cystoscopy, KUB, IVP, MRI abdomen, PT/INR, PSA, renogram, US kidney, urinalysis, and voiding cystourethrography.

- Refer to the Genitourinary System table at the back of the book for related tests by body system.
**Rheumatoid Factor**

**SYNONYM/ACRONYM:** RF, RA.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Nephelometry) 0 to 20 international units/mL.

**DESCRIPTION:** Individuals with rheumatoid arthritis harbor a macroglobulin-type antibody called *rheumatoid factor (RF)* in their blood. Patients with other diseases (e.g., systemic lupus erythematosus [SLE] and occasionally tuberculosis, chronic hepatitis, infectious mononucleosis, and subacute bacterial endocarditis) may also test positive for RF. RF antibodies are usually immunoglobulin (Ig) M but may also be IgG or IgA.

**INDICATIONS:** Assist in the diagnosis of rheumatoid arthritis, especially when clinical diagnosis is difficult.

**RESULT:**

*Increased in:*

Pathophysiology is unclear but RF is present in numerous conditions including rheumatoid arthritis.

- Chronic hepatitis
- Chronic viral infections
- Cirrhosis
- Dermatomyositis
- Infectious mononucleosis
- Leishmaniasis
- Leprosy
- Malaria
- Rheumatoid arthritis
- Sarcoidosis
- Scleroderma
- Sjögren’s syndrome
- SLE

**INTERFERING FACTORS:**

- Older patients may have higher values.
- Recent blood transfusion, multiple vaccinations or transfusions, or an inadequately activated complement may affect results.
- Serum with cryoglobulin or high lipid levels may cause a false-positive test and may require that the test be repeated after a fat-restriction diet.

**CRITICAL VALUES:** N/A

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the differential diagnosis and prognosis of arthritic diseases.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Access additional resources at davisplus.fadavis.com
Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to anticipated chronic pain resulting from joint inflammation, impairment in mobility, musculoskeletal deformity, and loss of independence. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, as appropriate. Provide contact information, if desired, for the Arthritis Foundation (www.arthritis.org).
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Advise the patient, as appropriate, that additional studies may be undertaken to determine treatment regimen or to determine the possible causes of symptoms if the test is negative for rheumatoid arthritis. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related laboratory tests include antibodies anti-cyclic citrullinated peptide, ANA, arthrogram, arthroscopy, biopsy bone, BMD, bone scan, CRP, calcium, collagen cross-linked telopeptides, CT spine, ESR, MRI musculoskeletal, osteocalcin, phosphorus, radiography bone, synovial fluid analysis, uric acid, vitamin D, and WBC scan.
- Refer to the Immune and Musculoskeletal System tables at the back of the book for related tests by body system.
**Rubella Antibodies**

**SYNONYM/ACRONYM:** German measles serology.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Indirect immunofluorescence) Immune or less than a fourfold increase in titer.

**DESCRIPTION:** Rubella, commonly known as German measles, is a communicable viral disease transmitted by contact with respiratory secretions and aerosolized droplets of the secretions. The incubation period is 14 to 21 days. This disease produces a pink, macular rash that disappears in 2 to 3 days. Rubella infection induces immunoglobulin (Ig) G and IgM antibody production. This test can determine current infection or immunity from past infection. Rubella serology is part of the TORCH (toxoplasmosis, rubella, cytomegalovirus, and herpes simplex type 2) panel routinely performed on pregnant women. Fetal infection during the first trimester can cause spontaneous abortion or congenital defects. Ideally the immune status of women of childbearing age should be ascertained before pregnancy, when vaccination can be administered to provide lifelong immunity. The presence of IgM antibodies indicates acute infection. The presence of IgG antibodies indicates current or past infection. Susceptibility to rubella is indicated by a negative reaction. Many laboratories use a qualitative assay that detects the presence of both IgM and IgG rubella antibodies. IgM- and IgG-specific enzyme immunoassays are also available to help distinguish acute infection from immune status. A rise in titer greater than fourfold in paired specimens is an indication of current infection.

**INDICATIONS:**
- Assist in the diagnosis of rubella infection
- Determine presence of rubella antibodies
- Determine susceptibility to rubella, particularly in pregnant women
- Perform as part of routine prenatal serological testing

**RESULT:**

**Positive findings in:**
- Rubella infection (past or present)

**CRITICAL VALUES:**
Note and immediately report to the health care provider (HCP) patients with a rubella-nonimmune status.

**INTERFERING FACTORS:** N/A

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

Access additional resources at davisplus.fadavis.com
Inform the patient that the test is used to identify rubella infection or immunity.

Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

Obtain a history of exposure to rubella.

Obtain a history of the patient’s immune and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm diagnosis. Any individual positive result should be repeated in 7 to 14 days to monitor a change in titer. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain to the patient that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

**Vaccination considerations:** Record the date of the last menstrual period and determine the possibility of pregnancy prior to administration of rubella vaccine to female rubella-nonimmune patients. Instruct patient not to become pregnant for 1 mo after being vaccinated with the rubella vaccine to protect any fetus from contracting the disease and having serious birth defects. Instruct on birth control methods to prevent pregnancy, if appropriate. Delay rubella vaccination in pregnancy until after childbirth, and give immediately prior to discharge from the hospital.

Recognize anxiety related to test results, and provide emotional support if results are positive and the patient is pregnant. Encourage the family to seek counseling if concerned with pregnancy termination. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Decisions regarding elective abortion should take place in the presence of both parents. Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks and difficulties of delivering and raising a developmentally challenged infant, as well as exploring other options (e.g., termination of pregnancy or adoption). Educate the patient in isolation precautions during time of communicability or contagion. Emphasize the need to return to have a convalescent blood sample taken in 7 to 14 days. Provide information regarding vaccine-preventable diseases where indicated (e.g., encephalitis, hepatitis A and B, human papillomavirus, influenza, measles, mumps, polio, rubella, smallpox, varicella, yellow fever). Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be
Rubeola Antibodies

**SYNONYM/ACRONYM:** Measles serology.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Indirect immunofluorescence) Negative or less than a fourfold increase in titer.

**DESCRIPTION:** Measles is caused by a single-stranded ribonucleic acid (RNA) paramyxovirus that invades the respiratory tract and lymphoreticular tissues. It is transmitted by respiratory secretions and aerosolized droplets of the secretions. The incubation period is 10 to 11 days. Symptoms initially include conjunctivitis, cough, and fever. Koplik's spots develop 4 to 5 days later, followed by papular eruptions, body rash, and lymphadenopathy. The presence of immunoglobulin (Ig) M antibodies indicates acute infection. The presence of IgG antibodies indicates current or past infection. Susceptibility to measles is indicated by a negative reaction. Many laboratories use a qualitative assay that detects the presence of both IgM and IgG rubeola antibodies. IgM- and IgG-specific enzyme immunoassays are also available to help distinguish acute infection from immune status. A rise in titer greater than fourfold in paired specimens is an indication of current infection.

**INDICATIONS:**
- Determine resistance to or protection against measles virus
- Differential diagnosis of viral infection, especially in pregnant women with a history of exposure to measles

**RESULT:**

**Positive findings in:**
- Measles infection

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:** N/A

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to identify rubeola infection or immunity.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
Obtain a history of exposure to measles.
Obtain a history of the patient’s immune and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm the diagnosis. Any individual positive result should be repeated in 7 to 14 days to monitor a change in titer. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient in isolation precautions during time of communicability or contagion. Emphasize the need to return to have a convalescent blood sample taken in 7 to 14 days. Provide information regarding vaccine-preventable diseases where indicated (e.g., encephalitis, hepatitis A and B, human papillomavirus, influenza, measles, mumps, polio, rubella, smallpox, varicella, yellow fever). Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include culture viral, rubella, and varicella.
- Refer to the Immune and Reproductive System tables at the back of the book for related tests by body system.
Schirmer Tear Test

SYNONYM/ACRONYM: N/A.

AREA OF APPLICATION: Eyelids.

DESCRIPTION: The tear film, secreted by the lacrimal, Krause, and Wolfring glands, covers the surface of the eye. Blinking spreads tears over the eye and moves them toward an opening in the lower eyelid known as the punctum. Tears drain through the punctum into the nasolacrimal duct and into the nose. The Schirmer tear test simultaneously tests both eyes to assess lacrimal gland function by determining the amount of moisture accumulated on standardized filter paper or strips, held against the conjunctival sac of each eye. The Schirmer test measures both reflex and basic secretion of tears. The Schirmer test number two measures basic tear secretion and is used to evaluate the accessory glands of Krause and Wolfring. The test is performed by instilling a topical anesthetic before insertion of filter paper. The topical anesthetic inhibits reflex tearing of major lacrimal glands by the filter paper, allowing testing of the accessory glands.

Abnormal findings in:
• Tearing deficiency related to aging, dry eye syndrome, or Sjögren’s syndrome
• Tearing deficiency secondary to leukemia, lymphoma, or rheumatoid arthritis

CRITICAL VALUES: N/A

INTERFERING FACTORS:
Factors that may impair clear imaging:
• Inability of the patient to remain still and cooperative during the test may interfere with the test results.
• Rubbing or squeezing the eyes may affect results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure measures the secretion of tears.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially topical anesthetic eyedrops.
• Obtain a history of the patient’s known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
• Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

INDICATIONS:
• Assess adequacy of tearing for contact lens comfort
• Assess suspected tearing deficiency

RESULT:
Normal findings in:
• 10 mm of moisture on test strip after 5 min. It may be slightly less than 10 mm in elderly patients.
Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.

Review the procedure with the patient. Address concerns about pain and explain that no pain will be experienced during the test, but there may be moments of discomfort. Explain to the patient that some discomfort may be experienced after the test when the numbness wears off from anesthetic drops administered prior to the test. Inform the patient that the test is performed by a health care provider (HCP) and takes about 15 min to complete.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Seat the patient comfortably. Instruct the patient to look straight ahead, keeping the eyes open and unblinking.

Instill topical anesthetic in each eye, as ordered, and provide time for it to work. Topical anesthetic drops are placed in the eye with the patient looking up and the solution directed at the six o’clock position of the sclera (white of the eye) near the limbus (grey, semitransparent area of the eyeball where the cornea and sclera meet). Neither the dropper nor the bottle should touch the eyelashes. Insert a test strip in each eye. The strip should be folded over the midportion of both lower eyelids.

POST-TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Assess for corneal abrasion caused by patient rubbing the eye before topical anesthetic has worn off.

Instruct the patient to avoid rubbing the eyes for 30 min after the procedure.

If appropriate, instruct the patient not to reinsert contact lenses for 2 hr.

Recognize anxiety related to test results, and be supportive of pain related to decreased lacrimation or inflammation. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information, if desired, for a general patient education Web site on the topic of eye care (e.g., www.allaboutvision.com).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include ANA, refraction, RF, and slit-lamp biomicroscopy.

Refer to the Ocular System table at the back of the book for related tests by body system.
Semen Analysis

SYNONYM/ACRONYM: N/A.

SPECIMEN: Semen from ejaculate specimen collected in a clean, dry, glass container known to be free of detergent. The specimen container should be kept at body temperature (37°C) during transportation.

REFERENCE VALUE: (Method: Macroscopic and microscopic examination)

DESCRIPTION: Semen analysis is a valid measure of overall male fertility. Semen contains a combination of elements produced by various parts of the male reproductive system. Spermatozoa are produced in the testes and account for only a small volume of seminal fluid. Fructose and other nutrients are provided by fluid produced in the seminal vesicles. The prostate gland provides acid phosphatase and other enzymes required for coagulation and liquefaction of semen. Sperm motility depends on the presence of a sufficient level of ionized calcium. If the specimen has an abnormal appearance (e.g., bloody, oddly colored, turbid), the patient may have an infection. Specimens can be tested with a leukocyte esterase strip to detect the presence of white blood cells.

INDICATIONS:  
- Assist in the diagnosis of azoospermia and oligospermia  
- Evaluate infertility  
- Evaluate effectiveness of vasectomy  
- Evaluate the effectiveness of vasectomy reversal  
- Support or disprove sterility in paternity suit

RESULT: There is marked intraindividual variation in sperm count. Indications of suboptimal fertility should be investigated by serial analysis of two to three samples collected over several months. If abnormal results are obtained, additional testing may be requested.
**Increased in:** N/A

**Decreased in:**
- Hyperpyrexia (*Unusual and abnormal elevation in body temperature may result in insufficient sperm production*)
- Infertility (*Related to insufficient production of sperm*)
- Obstruction of ejaculatory system
- Orchitis (*Insufficient sperm production usually related to viral infection, rarely bacterial infection*)
- Postvasectomy period (*Obstruction of the vas deferens*)
- Primary and secondary testicular failure (*Congenital, as in Kleinfelter syndrome, or acquired via infection*)
- Testicular atrophy (e.g., recovery from mumps)
- Varicocele (*Abnormal enlargement of the blood vessels in the scrotal area eventually damages testicular tissue and affects sperm production*)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs and substances that may decrease sperm count include arsenic, azathioprine, cannabis, cimetidine, cocaine, cyclophosphamide, estrogens, fluoxymesterone, ketoconazole, lead, methotrexate, methyltestosterone, nitrofurantoin, nitrogen mustard, procarbazine, sulfasalazine, and vincristine.
- Testicular radiation may decrease sperm counts.
- Cigarette smoking is associated with decreased production of semen.
- Caffeine consumption is associated with increased sperm density and number of abnormal forms.
- Delays in transporting the specimen and failure to keep the specimen warm during transportation are the most common reasons for specimen rejection.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of male infertility.
- Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient's immune and reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals.
- Note any recent procedures that can interfere with test results.
- Review the procedure with the patient. Instruct the patient to refrain from any sexual activity for 3 days before specimen collection. Instruct the patient to bring the specimen to the laboratory within 30 to 60 min of collection and to keep the specimen warm (close to body temperature) during transportation. The requesting
A health care provider (HCP) usually provides the patient with instructions for specimen collection. Address concerns about pain and explain that there should be no discomfort during the procedure.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

**Ejaculated Specimen:**
- Ideally, the specimen is obtained by masturbation in a private location close to the laboratory. In cases in which the patient expresses psychological or religious concerns about masturbation, the specimen can be obtained during coitus interruptus, through the use of a condom, or through postcoital collection of samples from the cervical canal and vagina of the patient’s sexual partner. The patient should be warned about the possible loss of the sperm-rich portion of the sample if coitus interruptus is the collection approach. If a condom is used, the patient must be carefully instructed to wash and dry the condom completely before use to prevent contamination of the specimen with spermicides.

**Cervical Vaginal Specimen:**
- Assist the patient to the lithotomy position on the examination table. A speculum is inserted, and the specimen is obtained by direct smear or aspiration of saline lavage.

**Specimens Collected from Skin or Clothing:**
- Dried semen may be collected by sponging the skin with a gauze soaked in saline or soaking the material in a saline solution.

**General:**
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Recognize anxiety related to test results. Provide a supportive, nonjudgmental environment when assisting a patient through the process of fertility testing. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Encourage the patient or family to seek counseling and other support services if concerned with infertility.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include antisperm antibodies, cancer antigens, chlamydia group antibodies, estradiol, FSH, hysterosalpingography, laparoscopy gynecologic, LH, testosterone, and US scrotal.
- Refer to the Immune and Reproductive System tables at the back of the book for related tests by body system.
Sickle Cell Screen

**SYNONYM/ACRONYM:** Sickle cell test.

**SPECIMEN:** Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

**REFERENCE VALUE:** (Method: Hemoglobin high-salt solubility) Negative.

**DESCRIPTION:** The sickle cell screen is one of several screening tests for a group of hereditary hemoglobinopathies. The test is positive in the presence of rare sickling hemoglobin (Hgb) variants such as Hgb S and Hgb C Harlem. Hgb S results from an amino acid substitution during Hgb synthesis whereby valine replaces glutamic acid. Hemoglobin C Harlem results from the substitution of lysine for glutamic acid. Individuals with sickle cell disease have chronic anemia because the abnormal Hgb is unable to carry oxygen. The red blood cells of affected individuals are also abnormal in shape, resembling a crescent or sickle rather than the normal disk shape. This abnormality, combined with cell-wall rigidity, prevents the cells from passing through smaller blood vessels. Blockages in blood vessels result in hypoxia, damage, and pain. Individuals with the sickle cell trait do not have the clinical manifestations of the disease but may pass the disease on to children if the other parent has the trait (or the disease) as well.

**RESULT:**

*Positive findings in:*

- Deoxygenated Hgb S is insoluble in the presence of a high-salt solution and will form a cloudy turbid suspension when present.
  - Combination of Hgb S with other hemoglobinopathies
  - Hgb C Harlem anemia
  - Sickle cell anemia
  - Sickle cell trait
  - Thalassemias

*Negative findings in:* N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

- Drugs that may increase sickle cells in vitro include prostaglandins.
- A positive test does not distinguish between the sickle trait and sickle cell anemia; to make this determination, follow-up testing by Hgb electrophoresis should be performed.
- False-negative results may occur in children younger than 3 mo of age.
- False-negative results may occur in patients who have received a recent blood transfusion before specimen collection, as a result of the dilutional effect.
- False-positive results may occur in patients without the trait or disease who have received a blood transfusion from a sickle cell–positive donor; this effect can last for 4 mo after the transfusion.

**INDICATIONS:**

- Detect sickled red blood cells
- Evaluate hemolytic anemias
Test results are unreliable if the patient has pernicious anemia or polycythemia.

**Nursing Implications and Procedure**

**Pretest:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to determine the presence of hemoglobin S.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**Intratest:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**Post-Test:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Advise the patient with sickle cell disease to avoid situations in which hypoxia may occur, such as strenuous exercise, staying at high altitudes, or traveling in an unpressurized aircraft. Obstetric and surgical patients with sickle cell anemia are at risk for hypoxia and therefore require close observation: Obstetric patients are at risk for hypoxia during the stress of labor and delivery, and surgical patients may become hypoxic while under general anesthesia.
- Recognize anxiety related to test results, and offer support, as appropriate. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services (www.sicklecelldisease.org).
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that further testing may be indicated if results are positive. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**Related Monographs:**
- Related tests include biopsy bone marrow, complete blood count, complete blood count, RBC morphology, ESR, Hgb electrophoresis, hemosiderin, LAP, MRI musculoskeletal, RBC cholinesterase, RBC indices, and US spleen.
- Refer to the Hematopoietic System table at the back of the book for related tests by body system.

Access additional resources at davisplus.fadavis.com
Slit-Lamp Biomicroscopy

**SYNONYM/ACRONYM:** Slit-lamp examination.

**AREA OF APPLICATION:** Eyes.

**CONTRAST:** N/A.

**DESCRIPTION:** This noninvasive procedure is used to visualize the anterior portion of the eye and its parts, including the eyelids and eyelashes, sclera, conjunctiva, cornea, iris, lens, and anterior chamber, and to detect pathology of any of these areas of the eyes. The slit lamp has a binocular microscope and light source that can be adjusted to examine the fluid, tissues, and structures of the eyes. Special attachments to the slit lamp are used for special studies and more detailed views of specific areas. Dilating drops or mydriatics may be used to enlarge the pupil in order to allow the examiner to see the eye in greater detail. Mydriatics work either by temporarily paralyzing the muscle that makes the pupil smaller or by stimulating the iris dilator muscle. Patients with blue or hazel eyes will dilate faster than patients with brown eyes.

- Detect deficiency in tear formation indicative of lacrimal dysfunction causing dry eye disease that can lead to corneal erosions or infection
- Detect lens opacities indicative of cataract formation
- Determine the presence of blepharitis, conjunctivitis, hordeolum, entropion, ectropion, trachoma, scleritis, and iritis
- Evaluate the fit of contact lenses

**RESULT:**

*Normal findings in:*
- Normal anterior tissues and structures of the eyes

*Abnormal findings in:*
- Blepharitis
- Conjunctivitis
- Corneal abrasions
- Corneal ulcers
- Ectropion
- Entropion
- Hordeolum
- Iritis
- Keratoconus (abnormal curvatures)
- Lens opacities
- Scleritis
- Trachoma

**CRITICAL VALUES:** N/A

**INDICATIONS:**
- Detect conjunctival and corneal injuries by foreign bodies and determine if ocular penetration or anterior chamber hemorrhage is present
- Detect corneal abrasions, ulcers, or abnormal curvatures (keratocoma)

**INTERFERING FACTORS:**
- Patients with narrow-angle glaucoma if pupil dilation is performed, as dilation can initiate a severe and
sight-threatening open-angle attack.

- Patients with allergies to mydriatics if pupil dilation using mydriatics is performed.
- Inability of the patient to cooperate and remain still during the procedure because of age, significant pain, or mental status may interfere with the test results.
- Failure to follow medication restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure detects abnormalities in the external and anterior eye structures.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially mydriatics if dilation is to be performed.
- Obtain a history of the patient’s known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- Obtain a history of symptoms and results of previously performed laboratory tests, diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Instruct the patient to remove contact lenses or glasses, as appropriate, unless the study is being done to check the fit and effectiveness of the contact lenses. Instruct the patient regarding the importance of keeping the eyes open for the test.
- Review the procedure with the patient. Address concerns about pain and explain that mydriatics, if used, may cause blurred vision and sensitivity to light. There may also be a brief stinging sensation when the drop is put in the eye. Inform the patient that a health care provider (HCP) performs the test, in a quiet, darkened room, and that to evaluate both eyes, the test can take up 30 min (including time for the pupils to dilate before the test is actually performed).
- **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food or fluid restrictions, unless by medical direction.
- The patient should withhold eye medications (particularly mydriatic eye drops if the patient has glaucoma) for at least 1 day prior to the procedure.
- Ensure that the patient understands that he or she must refrain from driving until the pupils return to normal (about 4 hr) after the test and has made arrangements to have someone else be responsible for transportation after the test.

**INTRATEST:**
- Ensure that the patient has complied with medication restrictions and pretesting preparations; assure that eye medications, especially mydriatics, have been restricted for at least 1 day prior to the procedure.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- Seat the patient comfortably. If dilation is to be performed, administer the ordered mydriatic to each eye and repeat in 5 to 15 min. Drops are placed in the eye with the patient looking up and the solution directed at the six o’clock position of the sclera (white of the eye) near the limbus (grey, semitransparent area of the eyeball)
where the cornea and sclera meet). Neither dropper nor bottle should touch the eyelashes.

- Ask the patient to place the chin in the chin rest and gently press the forehead against the support bar.
- The HCP places the slit lamp in front of the patient’s eyes in line with the examiner’s eyes. The external structures of the eyes are inspected with the special bright light and microscope of the slit lamp. The light is then directed into the patient’s eyes to inspect the anterior fluids and structures, and is adjusted for shape, intensity, and depth needed to visualize these areas. Magnification of the microscope is also adjusted to optimize visualization of the eye structures.
- Special attachments and procedures can also be used to obtain further diagnostic information about the eyes. These may include, for example, a camera to photograph specific parts, gonioscopy to determine anterior chamber closure, and a cobalt blue filter to detect minute corneal scratches, breaks, and abrasions with corneal staining.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual medications, as directed by the HCP.
- Recognize anxiety related to test results, and encourage the family to recognize and be supportive of impaired activity related to vision loss, anticipated loss of driving privileges, or the possibility of requiring corrective lenses (self-image). Discuss the implications of the abnormal test results on the patient’s lifestyle. Provide contact information, if desired, for a general patient education Web site on the topic of eye care (e.g., www.allaboutvision.com).
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that visual acuity and responses to light may change. Suggest that the patient wear dark glasses after the test until the pupils return to normal size. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include color perception test, fluorescein angiography, gonioscopy, intraocular muscle function, intraocular pressure, nerve fiber analysis, refraction, Schirmer tear test, and visual field testing.
- Refer to the Ocular System table at the back of the book for related tests by body system.

**Sodium, Blood**

**SYNONYM/ACRONYM:** Serum Na⁺.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

**REFERENCE VALUE:** (Method: Ion-selective electrode)
**DESCRIPTION:** Sodium is the most abundant cation in the extracellular fluid and, together with the accompanying chloride and bicarbonate anions, accounts for 92% of serum osmolality. Sodium plays a major role in maintaining homeostasis in a variety of ways, including maintaining the osmotic pressure of extracellular fluid, regulating renal retention and excretion of water, maintaining acid-base balance, regulating potassium and chloride levels, stimulating neuromuscular reactions, and maintaining systemic blood pressure. Hypernatremia (elevated sodium level) occurs when there is excessive water loss or abnormal retention of sodium. Hyponatremia (low sodium level) occurs when there is inadequate sodium retention or inadequate intake.

**INDICATIONS:**
- Determine whole-body stores of sodium, because the ion is predominantly extracellular
- Monitor the effectiveness of drug therapy, especially diuretics, on serum sodium levels

**RESULT:**

**Increased in:**
- Azotemia (**Related to increased renal retention**)
- Burns (**Hemoconcentration related to excessive loss of free water**)
- Cushing’s disease
- Dehydration
- Diabetes (**Dehydration related to frequent urination**)
- Diarrhea (**Water loss in excess of salt loss**)
- Excessive intake
- Excessive saline therapy (**IV fluids**)
- Excessive sweating (**Loss of free water can cause hemoconcentration**)
- Fever (**Loss of free water through sweating**)
- Hyperaldosteronism (**Excessive production of aldosterone increases renal absorption of sodium and increases blood levels**)
- Lactic acidosis (**Related to diabetes**)
- Nasogastric feeding with inadequate fluid (**Dehydration and hemoconcentration**)
- Vomiting (**Related to dehydration**)

**Decreased in:**
- Central nervous system disease
- Congestive heart failure (**Diminished renal blood flow due to reduced cardiac capacity decreases urinary excretion and increases blood sodium levels**)
- Cystic fibrosis (**Related to loss from chronic diarrhea; poor intestinal absorption**)
- Excessive antidiuretic hormone production (**Excessive loss through renal excretion**)
- Excessive use of diuretics (**Excessive loss through renal excretion; renal absorption is blocked**)
- Hepatic failure (**Hemodilution related to fluid retention**)

Access additional resources at davisplus.fadavis.com
• Hypoproteinemia (Related to fluid retention)
• Insufficient intake
• IV glucose infusion (Hypertonic glucose draws water into extracellular fluid and sodium is diluted)
• Mineralocorticoid deficiency (Addison’s disease) (Inadequate production of aldosterone results in decreased absorption by the kidneys)
• Nephrotic syndrome (Related to decreased ability of renal tubules to reabsorb sodium)

CRITICAL VALUES:

Hyponatremia: Less than 120 mmol/L
Hypernatremia: Greater than 160 mmol/L

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms especially fluid imbalance.

Signs and symptoms of hyponatremia include confusion, irritability, convulsions, tachycardia, nausea, vomiting, and loss of consciousness. Possible interventions include maintenance of airway, monitoring for convulsions, fluid restriction, and performance of hourly neurological checks. Administration of saline for replacement requires close attention to serum and urine osmolality.

Signs and symptoms of hypernatremia include restlessness, intense thirst, weakness, swollen tongue, seizures, and coma. Possible interventions include treatment of the underlying cause of water loss or sodium excess, which includes sodium restriction and administration of diuretics combined with IV solutions of 5% dextrose in water (D5W).

INTERFERING FACTORS:
• Drugs that may increase serum sodium levels include anabolic steroids, angiotensin, bicarbonate, carbenoxolone, cisplatin, corticotropin, cortisone, gamma globulin, and mannitol.
• Drugs that may decrease serum sodium levels include amphotericin B, bicarbonate, cathartics (excessive use), chlorpropamide, chlorothalidone, diuretics, ethacrynic acid, fluoxetine, furosemide, laxatives (excessive use), methylcloethiazide, metolazone, nicardipine, quinethazone, theophylline (IV infusion), thiadizides, and triamterene.
• Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is present in the IV solution, falsely increasing the result.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

▷ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
▷ Inform the patient that the test is used to evaluate electrolyte balance.
▷ Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
▷ Obtain a history of the patient’s endocrine and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
▷ Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
▷ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Nutritional considerations: Evaluate the patient for signs and symptoms of dehydration. Decreased skin turgor, dry mouth, and multiple longitudinal furrows in the tongue are symptoms of dehydration. Dehydration is a significant and common finding in geriatric and other patients in whom renal function has deteriorated.

Nutritional considerations: If appropriate, educate patients with low sodium levels that the major source of dietary sodium is found in table salt. Many foods, such as milk and other dairy products, are also good sources of dietary sodium. Most other dietary sodium is available through the consumption of processed foods. Patients on low-sodium diets should be advised to avoid beverages such as colas, ginger ale, sports drinks, lemon-lime sodas, and root beer. Many over-the-counter medications, including antacids, laxatives, analgesics, sedatives, and antitussives, contain significant amounts of sodium. The best advice is to emphasize the importance of reading all food, beverage, and medicine labels. In 1989, the Subcommittee on the 10th Edition of the RDA established 500 mg as the recommended maximum daily intake for dietary intake of sodium.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include ACTH, aldosterone, anion gap, ANP, BNP, blood gases, BUN, calculus kidney stone panel, BUN, calcium, carbon dioxide, chloride, chloride sweat, cortisol, creatinine, DHEAS, echocardiography, glucose, insulin, ketones, lactic acid, lung perfusion scan, magnesium, lactic acid, osmolality, potassium, renin, urine sodium, and UA. Refer to the Endocrine and Genitourinary System tables at the back of the book for related tests by body system.
**Sodium, Urine**

**SYNONYM/ACRONYM:** Urine Na+

**SPECIMEN:** Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

**REFERENCE VALUE:** (Method: Ion-selective electrode)

Values vary markedly depending on dietary intake and hydration state.

**DESCRIPTION:** Regulating electrolyte balance is a major function of the kidneys. In normally functioning kidneys, urine sodium levels increase when serum levels are high and decrease when serum levels are low to maintain homeostasis. Analyzing these urinary levels can provide important clues to the functioning of the kidneys and other major organs. There is diurnal variation in excretion of sodium, with values lower at night. Urine sodium tests usually involve timed urine collections over a 12- or 24-hr period. Measurement of random specimens may also be requested.

**INDICATIONS:**
- Determine potential cause of renal calculi
- Evaluate known or suspected endocrine disorder
- Evaluate known or suspected renal disease
- Evaluate malabsorption disorders

**RESULT:**
- Increased in:
  - Adrenal failure *(Inadequate production of aldosterone results in decreased renal sodium absorption)*
  - Diabetes *(Increased glucose levels result in hypertonic extracellular fluid; dehydration from excessive urination can cause hemoconcentration)*
  - Diuretic therapy *(Medication causes sodium to be lost by the kidneys)*
  - Excessive intake
  - Renal tubular acidosis *(Related to diabetes)*
• Salt-losing nephritis (Related to diminished capacity of the kidneys to reabsorb sodium)

**Decreased in:**
• Adrenal hyperfunction (Overproduction of aldosterone and other corticosteroids stimulate renal absorption of sodium decreasing urine sodium levels)
• Congestive heart failure (Decreased renal blood flow related to diminished cardiac output)
• Diarrhea (Related to decreased intestinal absorption; a decrease in blood levels will cause sodium to be retained by the kidneys and will lower urine sodium levels)
• Excessive sweating (Excessive loss of sodium through sweat; sodium will be retained by the kidneys)
• Extrarenal sodium loss with adequate hydration
• Insufficient intake
• Postoperative period (first 24 to 48 hr)
• Prerenal azotemia
• Sodium retention (Premenstrual)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
• Drugs that may increase urine sodium levels include acetazolamide, acetylsalicylic acid, amiloride, ammonium chloride, azosemide, benzthiazide, bumetanide, calcitonin, chlorothiazide, clopamide, cyclothiazide, diapamide, dopamine, ethacrynic acid, furosemide, hydrocortisone, hydroflumethiazide, isosorbide, levodopa, mercurial diuretics, methyclothiazide, metolazone, polythiazide, quinethazone, spironolactone, sulfates, tetracycline, thiazides, torasemide, triamterene, trichlormethiazide, triflocin, verapamil, and vincristine.
• Drugs that may decrease urine sodium levels include aldosterone, anesthetics, angiotensin, corticosteroids, cortisone, etodolac, indomethacin, levarterenol, lithium, and propranolol.
• Sodium levels are subject to diurnal variation (output being lowest at night), which is why 24-hr collections are recommended.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate acute renal failure and acute oliguria, and to assist in the differential diagnosis of hyponatremia.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.

Access additional resources at davisplus.fadavis.com
Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.

Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

Instruct the patient to cooperate fully and to follow directions.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date, and time of collection.

**Random Specimen (Collect in Early Morning):**

**Clean-catch specimen:**

Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.

Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

**Indwelling Catheter:**

Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

**Timed Specimen:**

Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.

Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.

If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.

At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.

Include on the collection container’s label the amount of urine, test start
and stop times, and any foods or medications that can affect test results.

**General:**
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.
- *Nutritional considerations:* If appropriate, educate patients with low sodium levels that the major source of dietary sodium is found in table salt. Many foods, such as milk and other dairy products, are also good sources of dietary sodium. Most other dietary sodium is available through the consumption of processed foods. Patients on low-sodium diets should be advised to avoid beverages such as colas, ginger ale, sports drinks, lemon-lime sodas, and root beer. Many over-the-counter medications, including antacids, laxatives, analgesics, sedatives, and antitussives, contain significant amounts of sodium. The best advice is to emphasize the importance of reading all food, beverage, and medicine labels. In 1989, the Subcommittee on the 10th Edition of the RDA established 500 mg as the recommended maximum daily intake for dietary intake of sodium.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ACTH, aldosterone, anion gap, ANP, BNP, blood gases, BUN, calcium, calculus kidney stone panel, carbon dioxide, chloride, chloride sweat, cortisol, creatinine, DHEAS, echocardiography, glucose, insulin, ketones, lactic acid, lung perfusion scan, magnesium, osmolality, potassium, renin, sodium, and UA.
- Refer to the Endocrine and Genitourinary System tables at the back of the book for related tests by body system.

**SYNONYM/ACRONYM:** SRT, Speech Reception Threshold.

**AREA OF APPLICATION:** Ears.

**CONTRAST:** N/A.
**DESCRIPTION:** This noninvasive speech audiometric procedure measures the degree of hearing loss for speech. The speech recognition threshold is the lowest hearing level at which speech can barely be recognized or understood. In this test, a number of spondaic words are presented to the patient at different intensities. Spondaic words, or spondees, are words containing two syllables that are equally accented or emphasized when they are spoken to the patient. The SRT is defined as the lowest hearing level at which the patient correctly repeats 50% of a list of spondaic words. Examples are airplane, hot dog, outside, ice cream, and baseball.

**INDICATIONS:**
- Determine appropriate gain during hearing aid selection
- Determine the extent of hearing loss related to speech recognition, as evidenced by the faintest level at which spondee words are correctly repeated
- Differentiate a real hearing loss from pseudohypoacusis
- Verify pure tone results

**RESULT:**

**Normal findings in:**
- Normal spondee threshold of about 6 to 10 dB (decibels) of the normal pure tone threshold with 50% of the words presented being correctly repeated at an appropriate intensity

**Abnormal findings in:**
- Conductive hearing loss
- High-frequency hearing loss
- Sensorineural hearing loss (acoustic nerve impairment)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

**Factors that may impair the results of the examination:**
- Inability of the patient to cooperate or remain still during the procedure because of age or mental status may interfere with the test results.
- Unfamiliarity with the language the words are presented in or with the words themselves will alter the results.
- Improper placement of the earphones and inconsistency in frequency of word presentation will affect results.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure measures hearing loss related to speech.
- Obtain a history of the patient’s complaints, including a list of known allergens.
- Obtain a history of the patient’s known or suspected hearing loss, including type and cause; ear conditions with treatment regimens; ear surgery; and other tests and procedures to assess and diagnose hearing deficit.
Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Ensure that the patient understands words and sounds in the language to be used for the test. Inform the patient that a series of words that change from loud to soft tones will be presented using earphones and that he or she will be asked to repeat the word. Explain that each ear is tested separately. Address concerns about pain and explain that no discomfort will be experienced during the test. Inform the patient that a health care provider (HCP) performs the test, in a quiet, soundproof room, and that the evaluation takes 5 to 10 min.

*Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.

Seat the patient on a chair in a sound-proof booth. Place the earphones on the patient’s head and secure them over the ears. The audiometer is set at 20 dB above the known pure tone threshold obtained from audiometry. The test represents hearing levels at speech frequencies of 500, 1000, and 2000 Hz.

The spondee words are presented to the ear with the best auditory response using a speech audiometer. The intensity is decreased and then increased to the softest sound at which the patient is able to hear the words and respond correctly to 50% of them. The procedure is then repeated for the other ear.

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Recognize anxiety related to test results, and be supportive of activity related to impaired hearing and perceived loss of independence. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Speech-Language-Hearing Association (www.asha.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

A related test is hearing loss audiometry.

Refer to the Auditory System table at the back of the book for related tests by body system.
Stereotactic Biopsy, Breast

SYNONYM/ACRONYM: N/A.

SPECIMEN: Breast tissue or cells.

REFERENCE VALUE: (Method: Macroscopic and microscopic examination of tissue) No abnormal cells or tissue.

DESCRIPTION: A stereotactic breast biopsy is helpful when a mammogram or ultrasound examination shows a mass, a cluster of microcalcifications (tiny calcium deposits that are closely grouped together), or an area of abnormal tissue change, usually with no lump being felt on a careful breast examination. A number of biopsy instruments and methods are utilized with x-ray guidance. They include core biopsy, which uses a large-bore needle to remove a generous sample of breast tissue, and a vacuum-assisted needle biopsy device. As an alternative to an open core surgical biopsy, which removes an entire breast lump for microscopic analysis, a narrow needle may be passed through the skin into the area under investigation. This accomplished with the help of special breast x-rays. Images of the breast are obtained with a mammography machine, and the images are recorded in a computer. An initial x-ray locates the abnormality and two stereo views are obtained, each angled 15° to either side of the initial image. The computer calculates how much the area of interest has changed with each image and is able to determine the exact site in three-dimensional space. A small sample of breast tissue is obtained and can show whether the breast mass is cancerous or not. A pathologist examines the tissue that was removed and makes a final diagnosis to allow for effective treatment.

INDICATIONS:
- A mammogram showing a suspicious cluster of small calcium deposits
- A mammogram showing a suspicious solid mass that cannot be felt on breast examination
- Evidence of breast lesion by palpation, mammography, or ultrasound
- New mass or area of calcium deposits present at a previous surgery site
- Observable breast changes such as “peau d’orange” skin, scaly skin of the areola, drainage from the nipple, or ulceration of the skin
- Patient preference for a nonsurgical method of lesion assessment
- Structure of the breast tissue is distorted

RESULT:
- Positive findings in carcinoma of the breast

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- This procedure is contraindicated in patients with bleeding disorders.
Factors that may impair clear imaging:
- Failure to restrict food intake before the study
- Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
- Complications of the procedure include hemorrhage, infection at the insertion site, and cardiac arrhythmias.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Consultation with a health care practitioner (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses a breast mass.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- Obtain a history of the patient’s reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). It is recommended that use be discontinued 14 days before surgical procedures. The requesting HCP and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that some pain will be experienced during the test, or there may be moments of discomfort. Inform the patient that the procedure is performed in a special room, usually a mammography suite, by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids or sedatives. Usually normal saline is infused.
- Instruct the patient to remove jewelry and other metallic objects from the area of the procedure.
- Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant.
- Instruct the patient to fast and restrict fluids for 4 hr prior to the procedure. Protocols may vary from facility to facility.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.
The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.

**INTRATEST:**

- Ensure that the patient has complied with dietary and medication restrictions for 4 hr prior to the procedure.
- Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.
- Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Have emergency equipment readily available.
- If the patient has a history of severe allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, date and time of collection, and site location (left or right breast). Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results. Record baseline vital signs and assess neurological status. Protocols may vary from facility to facility.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives. Place the patient in the prone or sitting position on an exam table. Cleanse the selected area, and cover with a sterile drape. A local anesthetic is injected at the site, and a small incision is made or a needle inserted. Instruct the patient to inhale deeply and hold his or her breath while the images are taken, and then to exhale after the images are taken. Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm). The needle or catheter is removed, and a pressure dressing is applied over the puncture site. Place tissue samples in properly labeled specimen containers, and promptly transport the specimens to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet and medications, as directed by the HCP. Monitor vital signs and neurological status every 15 min for 1 hour, then every 2 hr for 4 hr, and then as ordered by the HCP. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Observe the biopsy site for bleeding, inflammation, or hematoma formation. Advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Instruct the patient in the care and assessment of the site. Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to immediately report chills or fever. Instruct the patient to keep the site clean and change the dressing as needed.
- Recognize anxiety related to test results, and be supportive of the potential perceived loss of body image. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Cancer Society (www.cancer.org).
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include biopsy breast, CEA and cancer antigens, mammography, MRI breast, and US breast.
- Refer to the Reproductive System table at the back of the book for related tests by body system.

---

**Synovial Fluid Analysis**

**SYNONYM/ACRONYM:** Arthrocentesis, joint fluid analysis, knee fluid analysis.

**SPECIMEN:** Synovial fluid collected in a red-top tube for antinuclear antibodies (ANAs), complement, crystal examination, protein, rheumatoid factor (RF), and uric acid; sterile (red-top) tube for microbiological testing; lavender-top (EDTA) tube for complete blood count (CBC) and differential; gray-top (sodium fluoride [NaFl]) tube for glucose; green-top (heparin) tube for lactic acid and pH.

**REFERENCE VALUE:** (Method: Macroscopic evaluation of appearance; spectrophotometry for glucose, lactic acid, protein, and uric acid; Gram stain, acid-fast stain, and culture for microbiology; microscopic examination of fluid for cell count and evaluation of crystals; ion-selective electrode for pH; nephelometry for RF and C3 complement; indirect fluorescence for ANAs)

**Access additional resources at davisplus.fadavis.com**

ANA = antinuclear antibodies; C3 = complement; RF = rheumatoid factor; RBC = red blood cell; WBC = white blood cell; AFB = acid-fast bacilli.
**DESCRIPTION:** Synovial fluid analysis is performed via arthrocentesis, an invasive procedure involving insertion of a needle into the joint space. Synovial effusions are associated with disorders or injuries involving the joints. The most commonly aspirated joint is the knee, although samples also can be obtained from the shoulder, hip, elbow, wrist, and ankle, if clinically indicated. Joint disorders can be classified into five categories: noninflammatory, inflammatory, septic, crystal-induced, and hemorrhagic.

**INDICATIONS:**
- Assist in the evaluation of joint effusions
- Differentiate gout from pseudogout

**RESULT:**

**Fluid Values Increased in:**
- **Acute bacterial infection:** WBC count greater than $50 \times 10^3$/mm$^3$, marked predominance of neutrophils (greater than 90% neutrophils), positive Gram stain, positive cultures, possible presence of rice bodies, increased lactic acid (produced by bacteria), and complement levels paralleling those found in serum (may be elevated or decreased)
- **Gout:** WBC count variable: $0.5–200 \times 10^3$/mm$^3$ with a predominance of neutrophils (90% neutrophils), presence of monosodium urate crystals, increased uric acid, and complement levels paralleling those of serum (may be elevated or decreased)
- **Osteoarthritis, traumatic arthritis degenerative joint disease:** WBC count less than $3 \times 10^3$/mm$^3$ with less than 25% neutrophils and the presence of cartilage cells
- **Pseudogout:** Presence of calcium pyrophosphate crystals
- **Rheumatoid arthritis:** WBC count $3–50 \times 10^3$/mm$^3$ with a predominance of neutrophils (greater than 70% neutrophils), presence of rbc cells and possibly rice bodies, presence of cholesterol crystals if effusion is chronic, increased protein, increased lactic acid, and presence of rheumatoid factor
- **Systemic lupus erythematosus (SLE):** $3–50 \times 10^3$/mm$^3$ with a predominance of neutrophils, presence of SLE cells, and presence of antinuclear antibodies
- **Trauma, joint tumors, or hemophilic arthritis:** Elevated RBC count, increased protein level, and presence of fat droplets (if trauma involved)
- **Tuberculous arthritis:** WBC count $2–100 \times 10^3$/mm$^3$ with a predominance of neutrophils (up to 90% neutrophils), possible presence of rice bodies, presence of cholesterol crystals if effusion is chronic, in some cases a positive culture and smear for acid-fast bacilli (results frequently negative), and lactic acid

**Fluid Values Decreased in (Analytes in Parentheses are Decreased):**
- **Acute bacterial arthritis** (glucose and pH)
- **Gout** (glucose)
- **Rheumatoid arthritis** (glucose, pH, and complement)
- **SLE** (glucose, pH, and complement)
- **Tuberculous arthritis** (glucose and pH)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Blood in the sample from traumatic arthrocentesis may falsely elevate the RBC count.
- Undetected hypoglycemia or hyperglycemia may produce misleading glucose values.
Refrigeration of the sample may result in an increase in monosodium urate crystals secondary to decreased solubility of uric acid; exposure of the sample to room air with a resultant loss of carbon dioxide and rise in pH encourages the formation of calcium pyrophosphate crystals.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is primarily used to identify the presence and assist in the management of joint disease.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s immune and musculoskeletal systems, especially any bleeding disorders and other symptoms, as well as results of previously performed laboratory tests, diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to needle insertion through the joint space. Explain that any discomfort with the needle insertion will be minimized with local anesthetics and systemic analgesics. Explain that the anesthetic injection may cause an initial stinging sensation. Explain that, after the skin has been anesthetized, a large needle will be inserted through the joint space, and a “popping” sensation may be experienced as the needle penetrates the joint. Inform the patient that the procedure is performed by a health care provider (HCP) specializing in this procedure. The procedure usually takes approximately 20 min to complete.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no fluid restrictions unless by medical direction. Fasting for at least 12 hr before the procedure is recommended if fluid glucose measurements are included in the analysis. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**

- Ensure that the patient has complied with dietary and medication restrictions and pretesting preparations; assure that food has been restricted for at least 12 hr prior to the procedure. Ensure that anticoagulant medications and aspirin have been withheld, as ordered.
- Assemble the necessary equipment, including an arthrocentesis tray with solution for skin preparation, local anesthetic, a 20-mL syringe, needles of various sizes, sterile drapes, and sterile gloves for the tests to be performed.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and site location, especially left or right.
➧ Assist the patient into a comfortable sitting or supine position, as appropriate.

Prior to the administration of general or local anesthesia, shave the site and cleanse it with an antiseptic solution, and drape the area with sterile towels.

After the local anesthetic is administered, the needle is inserted at the collection site, and fluid is removed by syringe. Manual pressure may be applied to facilitate fluid removal.

If medication is injected into the joint, the syringe containing the sample is detached from the needle and replaced with the one containing the drug. The medication is injected with gentle pressure. The needle is withdrawn, and digital pressure is applied to the site for a few minutes. If there is no evidence of bleeding, a sterile dressing is applied to the site. An elastic bandage can be applied to the joint.

Monitor the patient for complications related to the procedure (allergic reaction, anaphylaxis).

Place samples in properly labeled specimen containers and promptly transport the specimens to the laboratory for processing and analysis. If bacterial culture and sensitivity tests are to be performed, record on the specimen containers any antibiotic therapy the patient is receiving.

POST-TEST:
➧ A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet and medications, as directed by the HCP.

After local anesthesia, monitor vital signs and compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

Assess puncture site for bleeding, bruising, inflammation, and excessive drainage of synovial fluid approximately every 4 hr for 24 hr and daily thereafter for several days.

Instruct the patient to report excessive pain, bleeding, or swelling to the requesting HCP immediately. Report to HCP if severe pain is present or the patient is unable to move the joint.

Assess for nausea and pain.

Administer antiemetic and analgesic medications as needed and as directed by the HCP.

Instruct the patient to apply an ice pack to the site for 24 to 48 hr.

Administer antibiotics, as ordered, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.

Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient or caregiver to handle linen and dispose of dressings cautiously, especially if septic arthritis is suspected. Instruct the patient to avoid excessive use of the joint for several days to prevent pain and swelling. Instruct the patient to return for a follow-up visit as scheduled. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
➧ Related tests include antibodies anti-cyclic citrullinated, ANA, arthrogram, arthroscopy, BMD, bone scan, CRP, cholesterol, complete blood count, complete blood count, WBC count and differential, ESR, MRI musculoskeletal, radiography bone, RF, synovial fluid analysis, and uric acid.

Refer to the Immune and Musculoskeletal System tables at the back of the book for related tests by body system.
**Syphilis Serology**

**SYNONYM/ACRONYM:** Automated reagin testing (ART), fluorescent treponemal antibody testing (FTA-ABS), microhemagglutination—*Treponema pallidum* (MHA-TP), rapid plasma reagin (RPR), treponemal studies, Venereal Disease Research Laboratory (VDRL) testing.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** (Method: Dark-field microscopy, rapid plasma reagin, enzyme-linked immunosorbent assay [ELISA], microhemagglutination, fluorescence) Nonreactive or absence of treponemal organisms.

**DESCRIPTION:** There are numerous methods for detecting *Treponema pallidum*, the organism known to cause syphilis. Syphilis serology is routinely ordered as part of a prenatal work-up and is required for evaluating donated blood units before release for transfusion. Selection of the proper testing method is important. Automated reagin testing (ART), rapid plasma reagin (RPR), and Venereal Disease Research Laboratory (VDRL) testing should be used for screening purposes. Fluorescent treponemal antibody testing (FTA-ABS) and microhemagglutination—*Treponema pallidum* (MHA-TP) are confirmatory methods for samples that screen positive or reactive. Cerebrospinal fluid should be tested only by the FTA-ABS method. Cord blood should not be submitted for testing by any of the aforementioned methods; instead, the mother’s serum should be tested to establish whether the infant should be treated.

**INDICATIONS:**
- Monitor effectiveness of treatment for syphilis
- Screen for and confirm the presence of syphilis

**RESULT:**

**Positive findings in:**
- Syphilis

**False-Positive or False-Reactive Findings in Screening (RPR, VDRL) Tests:**
- Infectious:
  - Bacterial endocarditis
  - Chancroid
  - Chickenpox
  - Human immunodeficiency virus
  - Infectious mononucleosis
  - Leprosy
  - Leptospirosis
  - Lymphogranuloma venereum
  - Malaria
  - Measles
  - Mumps
  - *Mycoplasma pneumoniae*
  - Pneumococcal pneumonia
  - Psittacosis
  - Relapsing fever
  - Rickettsial disease
  - Scarlet fever
  - Trypanosomiasis
Tuberculosis
Vaccinia (live or attenuated)
Viral hepatitis
• Noninfectious:
  Advanced cancer
  Advancing age
  Chronic liver disease
  Connective tissue diseases
  IV drug use
  Multiple blood transfusions
  Multiple myeloma and other immunological disorders
  Narcotic addiction
  Pregnancy

False-Positive or False-Reactive Findings in Confirmatory (FTA-ABS, MHA-TP) Tests:
• Infectious:
  Infectious mononucleosis
  Leprosy
  Leptospirosis
  Lyme disease
  Malaria
  Relapsing fever
• Noninfectious:
  Systemic lupus erythematosus

Negative findings in: N/A

CRITICAL VALUES:
Note and immediately report to the health care provider (HCP) positive results and related symptoms.

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE
PRETEST:
✓ Obtain a history of exposure.
✓ Obtain a history of the patient’s immune and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
✓ Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
✓ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

✓ There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
✓ If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
✓ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

✓ There are no food, fluid, or medication restrictions, unless by medical direction.

✓ Obtain a history of exposure.
✓ Obtain a history of the patient’s immune and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
✓ Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
✓ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

✓ There are no food, fluid, or medication restrictions, unless by medical direction.

POST-TEST:
✓ A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
✓ Recognize anxiety related to test results, and offer support. Counsel the patient, as appropriate, regarding the risk of transmission and proper
prophylaxis, and reinforce the importance of strict adherence to the treatment regimen. Inform the patient that positive findings must be reported to local health department officials, who will question him or her regarding sexual partners. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that repeat testing may be needed at 3-mo intervals for 1 yr to monitor the effectiveness of treatment. Answer any questions or address any concerns voiced by the patient or family.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Offer support, as appropriate, to patients who may be the victim of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nonthreatening atmosphere for a discussion during which risks of sexually transmitted diseases are explained. It is also important to discuss problems the patient may experience (e.g., guilt, depression, anger).

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include acid phosphatase, cerebrospinal fluid analysis, Chlamydia group antibody, culture bacterial anal, Gram stain, hepatitis B, hepatitis C, HIV, and β2-microglobulin.

Refer to the Immune and Reproductive System tables at the back of the book for related tests by body system.
**Testosterone, Total**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

**REFERENCE VALUE:** (Method: Immunochemiluminometric assay [ICMA])

**DESCRIPTION:** Testosterone is the major androgen responsible for sexual differentiation. In males, testosterone is made by the Leydig cells in the testicles and is responsible for spermatogenesis and the development of secondary sex characteristics. In females, the ovary and adrenal gland secrete small amounts of this hormone; however, most of the testosterone in females comes from the metabolism of androstenedione. In males, a testicular, adrenal, or pituitary tumor can cause an overabundance of testosterone, triggering precocious puberty. In females, adrenal tumors, hyperplasia, and medications can cause an overabundance of this hormone, resulting in masculinization or hirsutism.

**INDICATIONS:**

- Assist in the diagnosis of hypergonadism
- Assist in the diagnosis of male sexual precocity before age 10
- Distinguish between primary and secondary hypogonadism
- Evaluate hirsutism
- Evaluate male infertility

**RESULT:**

**Increased in:**

- Adrenal hyperplasia (Oversecretion of the androgen precursor DHEA)
- Adrenocortical tumors (Oversecretion of the androgen precursor DHEA)
- Hirsutism (Any condition that results in increased production of testosterone or its precursors)
- Hyperthyroidism (High thyroxine levels increase the production of sex hormone binding protein, which increases measured levels of total testosterone)
- Idiopathic sexual precocity (Related to stimulation of testosterone production by elevated levels of luteinizing hormone [LH])
- Polycystic ovaries (High estrogen levels increase the production of sex hormone binding protein, which increases measured levels of total testosterone)
- Syndrome of androgen resistance
- Testicular or extragonadal tumors (Related to excessive secretion of testosterone)
- Trophoblastic tumors during pregnancy
- Virilizing ovarian tumors

**Decreased in:**

- Anovulation
- Cryptorchidism (Related to dysfunctional testes)
- Delayed puberty
- Down syndrome (Related to diminished or dysfunctional testes)
- Excessive alcohol intake (Alcohol inhibits secretion of testosterone)
- Hepatic insufficiency (Related to decreased binding protein and reflects decreased measured levels of total testosterone)
- Impotence (Decreased testosterone levels can result in impotence)
- Klinefelter’s syndrome (Chromosome abnormality XXY associated with testicular failure)
- Malnutrition
- Myotonic dystrophy (Related to testicular atrophy)
- Orchietomy (Testosterone production occurs in the testes)
- Primary and secondary hypogonadism
- Primary and secondary hypopituitarism
- Uremia

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

- Drugs that may increase testosterone levels include barbiturates, bromocriptine, cimetidine, flutamide, gonadotropin, levonorgestrel, mifepristone, moclobemide, nafarelin (males), nilutamide, oral contraceptives, rifampin, and tamoxifen.
- Drugs that may decrease testosterone levels include cyclophosphamide, cyproterone, danazol, dexamethasone, diethylstilbestrol, digoxin, D-Trp-6-LHRH, fenoldopam, goserelin, ketoconazole, leuprolide, magnesium sulfate, medroxyprogesterone, methylprednisone, nandrolone,
oral contraceptives, pravastatin, prednisone, pyridoglutethimide, spironolactone, stanozolol, tetracycline, and thioridazine.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess gonadal and adrenal function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Recognize anxiety related to test results, and offer support, as appropriate. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include angiography adrenal gland scan, ACE, antibodies antisperm, biopsy thyroid, chromosome analysis, CT renal, DHEAS, estradiol, FSH, LH, PTH, RAIU, semen analysis, US scrotal, thyroid scan, TSH, and thyroxine.
- Refer to the Endocrine and Reproductive System tables at the back of the book for related test by body system.
**Thyroglobulin**

**SYNONYM/ACRONYM:** Tg.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** (Method: Chemiluminescent enzyme immunoassay)

**DESCRIPTION:** Thyroglobulin is an iodinated glycoprotein secreted by follicular epithelial cells of the thyroid gland. It is the storage form of the thyroid hormones thyroxine (T₄) and triiodothyronine (T₃). When thyroid hormones are released into the bloodstream, they split from thyroglobulin in response to thyroid-stimulating hormone. Values greater than 55 ng/mL are indicative of tumor recurrence in athyrotic patients.

**INDICATIONS:**
- Assist in the diagnosis of subacute thyroiditis
- Assist in the diagnosis of suspected disorders of excess thyroid hormone
- Management of differentiated or metastatic cancer of the thyroid
- Monitor response to treatment of goiter

**RESULT:**

**Increased in:**
Thyroglobulin is secreted by normal, abnormal, and cancerous thyroid tissue cells.
- Differentiated thyroid cancer
- Graves' disease (untreated) *(Autoimmune destruction of thyroid tissue cells)*
- Surgery or irradiation of the thyroid *(Elevated levels indicate residual or disseminated carcinoma)*
- T₄-binding globulin deficiency
- Thyroiditis *(Related to leakage from inflamed, damaged thyroid tissue cells)*
- Thyrotoxicosis

**Decreased in:**
- Administration of thyroid hormone *(Feedback loop suppresses production)*

Monitor T₄ therapy in patients with solitary nodules.

Access additional resources at davisplus.fadavis.com
• Congenital athryrosis (neonates) *(Related to insufficient synthesis)*
• Thyrotoxicosis factitia

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
• Drugs that may decrease thyroglobulin levels include neomycin and $T_4$.
• Autoantibodies to thyroglobulin can cause decreased values.
• Recent thyroid surgery or needle biopsy can interfere with test results.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate thyroid gland function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

*Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ACTH, albumin, ACE, antibodies thyroglobulin, biopsy thyroid, copper, follicle-stimulating hormone, growth hormone, luteinizing hormone, PTH, protein, RAU, TBII, thyroid scan, TSH, TSI, $T_4$, free $T_4$, $T_3$, free $T_3$, and US thyroid.
- Refer to the Endocrine System table at the back of the book for related tests by body system.
Thyroid-Binding Inhibitory Immunoglobulin

SYNONYM/ACRONYM: Thyrotropin receptor antibodies, thyrotropin-binding inhibitory immunoglobulin, TBII.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Radioreceptor) Less than 10% inhibition. (Note: In patients with Graves’ disease, inhibition is expected to be 10% to 100%).

RESULT:

Increased in:
Antibodies block the action of TSH and result in hyperthyroid conditions.

• Graves’ disease
• Hyperthyroidism (various forms)

Decreased in: N/A

CRITICAL VALUES: N/A

Find and print out the full monograph at DavisPlus (davisplus.fadavis.com, keyword Van Leeuwen).

Thyroid Scan

SYNONYM/ACRONYM: Thyroid scintiscan, iodine thyroid scan, technetium thyroid scan.

AREA OF APPLICATION: Thyroid.

CONTRAST: Oral radioactive iodine or IV technetium-99m pertechnetate.

DESCRIPTION: The thyroid scan is a nuclear medicine study performed to assess thyroid size, shape, position, and function; it is useful for evaluating thyroid nodules, multinodular goiter, and thyroiditis; assisting in the differential diagnosis of masses in the neck, base of the tongue, and mediastinum; and ruling out possible ectopic thyroid tissue in these areas. Thyroid scanning is performed after oral administration of radioactive iodine-123 (I-123) or I-131, or IV injection of technetium-99m (Tc-99m). Increased or decreased uptake by the thyroid gland and surrounding area and tissue is noted: Areas of increased radionuclide uptake (“hot spots”) are caused by hyperfunctioning thyroid nodules, which are usually nonmalignant; areas of decreased
uptake ("cold spots") are caused by hypofunctioning nodules, which are more likely to be malignant. Ultrasound imaging may be used to determine if the cold spot is a solid, semi-cystic lesion or a pure cyst (cysts are rarely cancerous). To determine whether the cold spot depicts a malignant neoplasm, however, a biopsy must be performed.

**INDICATIONS:**
- Assess palpable nodules and differentiate between a benign tumor or cyst and a malignant tumor
- Assess the presence of a thyroid nodule or enlarged thyroid gland
- Detect benign or malignant thyroid tumors
- Detect causes of neck or substernal masses
- Detect forms of thyroiditis (e.g., acute, chronic, Hashimoto’s)
- Detect thyroid dysfunction
- Differentiate between Graves’ disease and Plummer’s disease, both of which cause hyperthyroidism
- Evaluate thyroid function in hyperthyroidism and hypothyroidism (analysis combined with interpretation of laboratory tests, thyroid function panel including thyroxine and triiodothyronine, and thyroid uptake tests)

**RESULT:**

**Normal findings in:**
- Normal size, contour, position, and function of the thyroid gland with homogeneous uptake of the radionuclide

**Abnormal findings in:**
- Adenoma
- Cysts
- Fibrosis
- Goiter
- Graves’ disease (diffusely enlarged, hyperfunctioning gland)
- Hematoma
- Metastasis
- Plummer’s disease (nodular hyperfunctioning gland)
- Thyroiditis (Hashimoto’s)
- Thyrotoxicosis
- Tumors, benign or malignant

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

*This procedure is contraindicated for:*
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus or mother

*Factors that may impair clear imaging:*
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Other nuclear scans or iodinated contrast medium radiographic studies done within the previous 24 to 48 hr
- Ingestion of foods containing iodine (iodized salt) or medications containing iodine (cough syrup, potassium iodide, vitamins, Lugol’s solution, thyroid replacement medications), which can decrease the uptake of the radionuclide
- Antithyroid medications (propylthiouracil), corticosteroids, antihistamines, warfarin, sulfonamides, nitrates, corticosteroids, thyroid hormones, and isoniazid, which can decrease the uptake of the radionuclide
- Increased uptake of iodine in persons with an iodine-deficient diet or who are on phenothiazine therapy
Vomiting and severe diarrhea, which can affect absorption of orally administered radionuclide
Gastroenteritis, which can interfere with absorption of orally administered radionuclide
Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

**Other considerations:**
- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue can produce erroneous hot spots.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses thyroid function and structure.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, or anesthetics.
- Ensure thyroid blood tests are completed prior to this procedure.
- Note any recent procedures that can interfere with test results, including examinations using iodinated contrast medium or radioactive nuclides.
- Radiographic procedures done with iodinated contrast medium should be scheduled after this procedure is completed.
- Obtain a history of results of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test. Inform the patient that the procedure is performed in a nuclear medicine department, usually by a HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- The patient should fast for 8 to 12 hr prior to the procedure. Protocols may vary from facility to facility.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**
- Ensure that the patient has complied with dietary restrictions for 8 to 12 hr prior to the procedure.
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Ask the patient to lie still during the procedure because movement produces unclear images.

Observe standard precautions, and follow the general guidelines in Appendix A.

Administer sedative to a child or to an uncooperative adult, as ordered.

Tc-99m pertechnetate is injected IV 20 min before scanning.

If oral radioactive nuclide is used instead, administer I-123 24 hr before scanning.

Place the patient in a supine position on a flat table to obtain images of the neck area.

Remove the needle or catheter and apply a pressure dressing over the puncture site.

**POST-TEST:**

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

Instruct the patient in the care and assessment of the injection site.

Instruct the patient to resume pretesting diet as directed by the HCP.

Advise the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hr.

If a woman who is breastfeeding must have a nuclear scan, she should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.

Instruct the patient to flush the toilet immediately, and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.

Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.

Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include ACTH, angiography adrenal, biopsy thyroid, calcium, CT renal, cortisol, glucose, radioactive iodine uptake, sodium, thyroglobulin, thyroid antibodies, TBII, thyroid scan, TSH, TT3, and US thyroid.

Refer to the Endocrine System table in the back of the book for related tests by body system.
Thyroid-Stimulating Hormone

SYNONYM/ACRONYM: Thyrotropin, TSH.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube; for a neonate, use filter paper.

REFERENCE VALUE: (Method: Immunoassay)

DESCRIPTION: Thyroid-stimulating hormone (TSH) is produced by the pituitary gland in response to stimulation by thyrotropin-releasing hormone (TRH), a hypothalamic-releasing factor. TRH regulates the release and circulating levels of thyroid hormones in response to variables such as cold, stress, and increased metabolic need. Thyroid and pituitary function can be evaluated by TSH measurement. TSH exhibits diurnal variation, peaking between midnight and 4 a.m. and troughing between 5 and 6 p.m. TSH values are high at birth but reach adult levels in the first week of life. Elevated TSH levels combined with decreased thyroxine (T₄) levels indicate hypothyroidism and thyroid gland dysfunction. In general, decreased TSH and T₄ levels indicate secondary congenital hypothyroidism and pituitary hypothalamic dysfunction. A normal TSH level and a depressed T₄ level may indicate (1) hypothyroidism owing to a congenital defect in T₄-binding globulin, or (2) transient congenital hypothyroidism owing to hypoxia or prematurity. Early diagnosis and treatment in the neonate are crucial for the prevention of cretinism and mental retardation.

INDICATIONS:
• Assist in the diagnosis of congenital hypothyroidism
• Assist in the diagnosis of hypothyroidism or hyperthyroidism or suspected pituitary or hypothalamic dysfunction
• Differentiate functional euthyroidism from true hypothyroidism in debilitated individuals

RESULT:
Increased in:
A decrease in thyroid hormone levels activates the feedback loop to increase production of TSH.
• Congenital hypothyroidism in the neonate (filter paper test)

Access additional resources at davisplus.fadavis.com
• Ectopic TSH-producing tumors (lung, breast)
• Primary hypothyroidism
• Secondary hyperthyroidism owing to pituitary hyperactivity
• Thyroid hormone resistance
• Thyroiditis (Hashimoto’s autoimmune disease)

**Decreased in:**
An increase in thyroid hormone levels activates the feedback loop to decrease production of TSH.

• Excessive thyroid hormone replacement
• Graves’ disease
• Primary hyperthyroidism
• Secondary hypothyroidism (Related to pituitary involvement that decreases production of TSH)
• Tertiary hypothyroidism (Related to hypothalamic involvement that decreases production of TRH)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
• Drugs and hormones that may increase TSH levels include amiodarone, benserazide, erythrosine, flunarizine (males), iobenzamic acid, iodides, lithium, methimazole, metoclopramide, morphine, propranolol, radiographic agents, TRH, and valproic acid.
• Drugs and hormones that may decrease TSH levels include acetylsalicylic acid, amiodarone, anabolic steroids, carbamazepine, corticosteroids, dopamine, glucocorticoids, hydrocortisone, insulin-like growth factor-1, interferon-alfa-2b, iodamide, josamycin, levodopa, levothyroxine, methergoline, nifedipine, pyridoxine, T₁, and triiodothyronine (T₃).
• Failure to let the filter paper sample dry may affect test results.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate thyroid gland function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.
**Filter Paper Test (Neonate):**
- Obtain kit and cleanse heel with antiseptic. Observe standard precautions, and follow the general guidelines in Appendix A. Use gauze to dry the stick area completely. Perform heel stick, gently squeeze infant's heel, and touch filter paper to the puncture site. Completely fill the circles on the filter paper, saturating the filter paper with blood. Apply pressure to the heel stick with a gauze pad to stop the bleeding. Allow the filter paper to dry thoroughly, label the specimen, and promptly transport it to the laboratory. Alternatively, if a specimen collection kit is used, follow instructions for labeling and mailing to the testing laboratory.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

**Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.**

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ACTH, albumin, ACE, antibodies antithyroglobulin, biopsy thyroid, copper, follicle-stimulating hormone, growth hormone, luteinizing hormone, PTH, protein, RAIU, thyroglobulin, TSI, TBII, thyroid scan, T4, free T4, T3, free T3, and US thyroid.
- Refer to the Endocrine System table at the back of the book for related tests by body system.

---

**Thyroid-Stimulating Immunoglobulin**

**SYNONYM/ACRONYM:** Thyrotropin receptor antibodies, TSI.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Animal cell transfection with luciferase marker)
- Less than 130% of basal activity.

**DESCRIPTION:** There are two functional types of thyroid receptor immunoglobulins: *thyroid-stimulating immunoglobulin (TSI)* and *thyroid-binding inhibitory immunoglobulin (TBII)*. TSI reacts with the receptors, activates intracellular enzymes, and promotes epithelial cell activity that operates outside the feedback regulation for thyroid-stimulating hormone (TSH); TBII blocks the action of TSH and is believed to cause certain types of hyperthyroidism (see monograph titled “Thyroid-Binding Inhibitory Immunoglobulin”). These antibodies were formerly known as *long-acting thyroid stimulators*. High levels in pregnancy may have some predictive value for...
neonatal thyrotoxicosis: A positive result indicates that the antibodies are stimulating (TSI); a negative result indicates that the antibodies are blocking (TBII). TSI testing measures thyroid receptor immunoglobulin levels in the evaluation of thyroid disease.

INDICATIONS:
- Follow-up to positive TBII assay in differentiating antibody stimulation from neutral or suppressing activity
- Monitor hyperthyroid patients at risk for relapse or remission

RESULT:

Increase in:
Graves’ disease (This form of hyperthyroidism has an autoimmune component; the antibodies stimulate release of thyroid hormones outside the feedback loop that regulates TSH levels)

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Lithium may cause false-positive TBII results.

Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

INTRA-TEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further treatment or follow-up.
testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ACTH, albumin, ACE, antibodies antithyroglobulin, biopsy thyroid, copper, follicle-stimulating hormone, growth hormone, luteinizing hormone, PTH, protein, RAIU, thyroglobulin, TBII, thyroid scan, TSH, T₄, free T₄, T₃, free T₃, and US thyroid.
- Refer to the Endocrine System table at the back of the book for related tests by body system.

**DESCRIPTION:** Thyroxine-binding globulin (TBG) is the predominant protein carrier for circulating thyroxine (T₄) and triiodothyronine (T₃). T₄-binding prealbumin and T₄-binding albumin are the other transport proteins. Conditions that affect TBG levels and binding capacity also affect free T₃ and free T₄ levels.

**INDICATIONS:**
- Differentiate elevated T₄ due to hyperthyroidism from increased TBG binding in euthyroid patients
- Evaluate hypothyroid patients
- Identify deficiency of or excess TBG due to hereditary abnormality

**RESULT:**
- **Increased in:** Acute intermittent porphyria
  
  *Pathophysiology is not well understood*

Access additional resources at davisplus.fadavis.com
Estrogen therapy (TBG is increased in the presence of exogenous or endogenous estrogens)

- Genetically high TBG (Rare)
- Hyperthyroidism (Related to increased levels of total thyroxine available for binding)
- Infectious hepatitis and other liver diseases (Pathophysiology is not well understood)
- Neonates
- Pregnancy (TBG is increased in the presence of exogenous or endogenous estrogens)

Decreased in:
- Acromegaly
- Chronic hepatic disease (General decrease in protein synthesis)
- Genetically low TBG
- Major illness (General decrease in protein synthesis)
- Marked hypoproteinemia, malnutrition (General decrease in protein synthesis)
- Nephrotic syndrome (General increase in protein loss)
- Ovarian hypofunction (TBG is decreased in the absence of estrogens)
- Surgical stress (General decrease in protein synthesis)
- Testosterone-producing tumors (TBG is decreased in the presence of testosterone)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs and hormones that may increase TBG levels include estrogens, oral contraceptives, perphenazine, and tamoxifen.
- Drugs that may decrease TBG levels include anabolic steroids, androgens, asparaginase, corticosteroids, corticotropin, danazol, phenytoin, and propranolol.

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate thyroid gland function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.
A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include antibodies antithyroglobulin, thyroglobulin, TBII, thyroid scan, TSH, TSI, T3, free T3, T4, free T4, and US thyroid.
- Refer to the Endocrine System table at the back of the book for related tests by body system.

### Thyroxine, Free

**SYNONYM/ACRONYM:** Free T4, FT4.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

**REFERENCE VALUE:** (Method: Immunoassay)

**DESCRIPTION:** Thyroxine (T4) is a hormone produced and secreted by the thyroid gland. Newborns are commonly tested for decreased T4 levels by a filter paper method (see monograph titled “Thyroxine, Total”). Most T4 in the serum (99.97%) is bound to thyroxine-binding globulin (TBG), prealbumin, and albumin. The remainder (0.03%) circulates as unbound or free T4, which is the physiologically active form. Levels of free T4 are proportional to levels of total T4. The advantage of measuring free T4 instead of total T4 is that, unlike total T4 measurements, free T4 levels are not affected by fluctuations in TBG levels; as a result, free T4 levels are considered the most accurate indicator of T4 and its thyrometabolic activity. Free T4 measurements are useful in evaluating thyroid disease.

Access additional resources at davisplus.fadavis.com
when thyroid-stimulating hormone (TSH) levels alone provide insufficient information. Free $T_4$ and TSH levels are inversely proportional. Measurement of free $T_4$ is also recommended during treatment for hyperthyroidism, until symptoms have abated and levels have decreased into the normal range.

**INDICATIONS:**
- Evaluate signs of hypothyroidism or hyperthyroidism
- Monitor response to therapy for hypothyroidism or hyperthyroidism

**RESULT:**

*Increased in:*
- Hyperthyroidism (*Thyroxine is produced independently of stimulation by TSH*)
- Hypothyroidism treated with $T_4$ (*Laboratory tests do not distinguish between endogenous and exogenous sources*)

*Decreased in:*
- Hypothyroidism (*Thyroid hormones are not produced in sufficient quantities regardless of TSH levels*)
- Pregnancy (late)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase free $T_4$ levels include acetylsalicylic acid, amiodarone, halofenate, heparin, iopanoic acid, levothyroxine, methimazole, and radiographic agents.
- Drugs that may decrease free $T_4$ levels include amiodarone, anabolic steroids, asparaginase, methadone, methimazole, oral contraceptives, and phenylbutazone.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate thyroid gland function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

as unbound or free $T_4$, which is the physiologically active form. Levels of free $T_4$ are proportional to levels of total $T_4$. The advantage of measuring free $T_4$ instead of total $T_4$ is that, unlike total $T_4$ measurements, free $T_4$ levels are not affected by fluctuations in TBG levels; as a result, free $T_4$ levels are considered the most accurate indicator of $T_4$ and its thyrometabolic activity (see monograph titled “Thyroxine, Free”).

**INDICATIONS:**
- Evaluate signs of hypothyroidism or hyperthyroidism and neonatal screening for congenital hypothyroidism (required in all 50 states)
- Evaluate thyroid response to protein deficiency associated with severe illnesses
- Monitor response to therapy for hypothyroidism or hyperthyroidism

**RESULT:**

**Increased in:**
- Acute psychiatric illnesses *(Pathophysiology is unknown although there is a relationship between thyroid hormone levels and certain types of mental illness)*
- Excessive intake of iodine *(Iodine is rapidly taken up by the body to form thyroxine)*
- Hepatitis *(Related to decreased production of TBG by damaged liver cells)*
- Hyperthyroidism *(Thyroxine is produced independently of stimulation by TSH)*
- Obesity
- Thyrotoxicosis due to Graves’ disease *(Thyroxine is produced independently of stimulation by TSH)*

**Decreased in:**
- Decreased TBG *(Nephrotic syndrome, liver disease, gastrointestinal protein loss, malnutrition)*
- Hypothyroidism *(Thyroid hormones are not produced in sufficient quantities regardless of TSH levels)*
- Panhypopituitarism *(The dysfunctional pituitary gland does not secrete enough thyrotropin to stimulate the thyroid to produce thyroxine)*
- Strenuous exercise

**CRITICAL VALUES:**

**Hypothyroidism:**
Less than 2.0 mcg/dL

**Hyperthyroidism:**
Greater than 20.0 mcg/dL

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms.

At levels less than 2.0 mcg/dL, the patient is at risk for myxedema coma. Signs and symptoms of severe hypothyroidism include hypothermia, hypotension, bradycardia, hypoventilation, lethargy, and coma. Possible interventions include airway support, hourly monitoring for neurological function and blood pressure, and administration of IV thyroid hormone.

At levels greater than 20.0 mcg/dL, the patient is at risk for thyroid storm. Signs and symptoms of severe hyperthyroidism include hyperthermia, diaphoresis, vomiting, dehydration, and shock. Possible interventions include supportive treatment for shock, fluid and electrolyte replacement for dehydration, and administration of anti-thyroid drugs (propylthiouracil and Lugol’s solution).
INTERFERING FACTORS:

- Drugs that may increase T4 levels include amiodarone, amphetamines, corticosteroids, ether, fluorouracil, glucocorticoids, halofenate, insulin, iobenzamic acid, ipanoic acid, ipodate, levaterenol, levodopa, levothyroxine, opiates, oral contraceptives, phenothiazine, and propranolol.

- Drugs, substances, and treatments that may decrease T4 levels include acetylsalicylic acid, aminoglutethimide, aminosalicylic acid, amiodarone, anabolic steroids, anticonvulsants, aspirinase, barbiturates, carbimazole, chlorpromazine, chlorpropamide, cholestyramine, clofibrate, cobalt, colchicine, corticotropin, cortisol, cotrimoxazole, cytostatic therapy, danazol, dehydroepiandrosterone, dexamethasone, diazepam, diazo dyes (e.g., Evans blue), dinitrophenol, ethionamide, fenclofenac, halofenate, hydroxyphenylpyruvic acid, interferon alpha-2b, iodothiouracil, iron, isotretinoin, liothyronine, lithium, lovastatin, methimazole, methylthiouracil, mitotane, norethindrone, penicillamine, penicillin, phenylacetic acid derivatives, phenylbutazone, potassium iodide, propylthiouracil, reserpine, salicylate, sodium nitroprusside, stanozolol, sulfonylureas, tetra-chlorothyronine, tolbutamide, and triiodothyronine (T3).

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate thyroid gland function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INRATEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing.
treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include ACTH, albumin, ACE, antibodies antithyroglobulin, biopsy thyroid, copper, follicle-stimulating hormone, growth hormone, luteinizing hormone, PTH, protein, RAIU, thyroglobulin, TBII, thyroid scan, TSH, TSI, free T4, T3, free T3, and US thyroid.
- Refer to the Endocrine System table at the back of the book for related tests by body system.

---

**Toxoplasma Antibody**

**SYNONYM/ACRONYM:** Toxoplasmosis serology, toxoplasmosis titer.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: Indirect fluorescent antibody) Negative or less than a fourfold increase in titer.

**DESCRIPTION:** Toxoplasmosis is a severe, generalized granulomatous central nervous system disease caused by the protozoan *Toxoplasma gondii*. Transmission to humans occurs by ingesting undercooked meat or handling contaminated matter such as cat litter. Immunoglobulin (Ig) M antibodies develop approximately 5 days after infection and can remain elevated for 3 wk to several mo. IgG antibodies develop approximately 1 to 2 wk after infection and can remain elevated for months or years. *Toxoplasma* serology is part of the TORCH (toxoplasmosis, rubella, cytomegalovirus, and herpes simplex type 2) panel routinely performed on pregnant women. Fetal infection during the first trimester can cause spontaneous abortion or congenital defects. Immunocompromised individuals are also at high risk for serious complications if infected. The presence of IgM antibodies indicates acute or congenital infection; the presence of IgG antibodies indicates current or past infection.

**INDICATIONS:**
- Assist in establishing a diagnosis of toxoplasmosis
- Document past exposure or immunity
- Serological screening during pregnancy

**RESULT:**

**Positive findings in**
- *Toxoplasma* infection
CRITICAL VALUES: N/A
INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis of toxoplasmosis and to document history of previous exposure or immunity.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of exposure.
- Obtain a history of the patient’s immune and reproductive systems, a history of other potential sources of exposure, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm the diagnosis. Any individual positive result should be repeated in 3 wk to monitor a change in titer. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Recognize anxiety related to test results, and provide emotional support if results are positive and the patient is pregnant and/or immunocompromised. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient in isolation precautions during time of communicability or contagion. Emphasize the need to return to have a convalescent blood sample taken in 3 wk. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include CMV, fetal fibronectin, and rubella.
- Refer to the Immune and Reproductive System tables at the back of the book for related tests by body system.
Transferrin

SYNONYM/ACRONYM: Siderophilin, TRF.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Nephelometry)

</tr>
</tbody>
</table>

DESCRIPTION: Transferrin is a glycoprotein formed in the liver. It transports circulating iron obtained from dietary intake and red blood cell breakdown. Transferrin carries 50% to 70% of the body’s iron; normally it is approximately one-third saturated. Inadequate transferrin levels can lead to impaired hemoglobin synthesis and anemia. Transferrin is subject to diurnal variation, and it is responsible for the variation in levels of serum iron throughout the day. (See monograph titled “Iron-Binding Capacity [Total], Transferrin, and Iron Saturation.”)

INDICATIONS:
- Determine the iron-binding capacity of the blood
- Evaluate iron metabolism in iron-deficiency anemia
- Evaluate nutritional status
- Screen for hemochromatosis

RESULT:

Increased in:
- Estrogen therapy (Estrogen stimulates the liver to produce transferrin)

Decreased in:
- Iron-deficiency anemia (The liver produces transferrin in response to decreased iron levels)
- Pregnancy (The liver produces transferrin in response to anemia of pregnancy)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs that may increase transferrin levels include carbamazepine, danazol, mestranol, and oral contraceptives.
• Drugs that may decrease transferrin levels include cortisone and dextran.
• Transferrin levels are subject to diurnal variation and should be collected in the morning, when levels are highest.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is primarily used to evaluate nutritional status (e.g., iron-deficiency anemia).
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to fast for at least 12 hr before specimen collection.
- There are no fluid or medication restrictions, unless by medical direction.

**INTRATEST:**
- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 12 hr prior to the procedure.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume usual diet, as directed by the HCP.
- **Nutritional considerations:** Educate the patient with abnormal iron values that numerous factors affect the absorption of iron, enhancing or decreasing absorption regardless of the original content of the iron-containing dietary source. Consumption of large amounts of alcohol damages the intestine and allows increased absorption of iron. A high intake of calcium and ascorbic acid also increases iron absorption. Iron absorption after a meal is also increased by factors in meat, fish, or poultry. Iron absorption is decreased by the absence (gastric resection) or diminished presence (use of antacids) of gastric acid. Phytic acids from cereals, tannins from tea and coffee, oxalic acid from vegetables, and minerals such as copper, zinc, and manganese interfere with iron absorption.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
Triglycerides

SYNONYM/ACRONYM: Trigs, TG.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

REFERENCE VALUE: (Method: Spectrophotometry)

DESCRIPTION: Triglycerides are a combination of three fatty acids and one glycerol molecule. They are necessary to provide energy for various metabolic processes. Excess triglycerides are stored in adipose tissue, and the fatty acids provide the raw materials needed for conversion to glucose (gluconeogenesis) or for direct use as an energy source. Although fatty acids originate in the diet, many are also derived from unused glucose and amino acids that the liver converts into stored energy. Beyond triglyceride, total cholesterol, high-density lipoprotein (HDL) and low-density lipoprotein (LDL) cholesterol values, other important risk factors must be considered. The Framingham algorithm can assist in estimating the risk of developing coronary artery disease (CAD) within a 10-yr period. The National Cholesterol Education Program (NCEP) also provides important guidelines. The latest NCEP guidelines for target lipid levels, major risk factors, and therapeutic
TRIGLYCERIDES

INDICATIONS:
• Evaluate known or suspected disorders associated with altered triglyceride levels
• Identify hyperlipoproteinemia (hyperlipidemia) in patients with a family history of the disorder
• Monitor the response to drugs known to alter triglyceride levels
• Screen adults who are either over 40 y.o. or obese to estimate the risk for atherosclerotic cardiovascular disease

RESULT:
Increased in:
• Acute myocardial infarction (Elevated TG is identified as an independent risk factor in the development of CAD)
• Alcoholism (Related to decreased breakdown of fats in the liver and increased blood levels)
• Anorexia nervosa (Compensatory increase, secondary to starvation)
• Chronic ischemic heart disease (Elevated TG is identified as an independent risk factor in the development of CAD)
• Cirrhosis (Increased TG blood levels related to decreased breakdown of fats in the liver)
• Glycogen storage disease (G6PD deficiency, e.g., von Gierke’s disease, results in hepatic overproduction of very-low-density lipoprotein [VLDL] cholesterol, the TG-rich lipoprotein)
• Gout (TG is frequently elevated in patients with gout, possibly related to alterations in apolipoprotein E genotypes)
• Hyperlipoproteinemia (Related to increase in transport proteins)
• Hypertension (Associated with elevated TG, which is identified as an independent risk factor in the development of CAD)
• Hypothyroidism (Significant relationship between elevated TG and decreased metabolism)
• Impaired glucose tolerance (Increase in insulin stimulates production of TG by liver)
• Metabolic syndrome (Syndrome consisting of obesity, high blood pressure, and insulin resistance)
• Nephrotic syndrome (Related to absence or insufficient levels of lipoprotein lipase to remove circulating TG and to decreased catabolism of TG-rich VLDL lipoproteins)
• Obesity (Significant and complex relationship between obesity and elevated TG)
• Pancreatitis (Acute and chronic; related to effects on insulin production)
• Pregnancy (Increased demand for production of hormones related to pregnancy)
• Renal failure (Related to diabetes; elevated insulin levels stimulate production of TG by liver)
• Respiratory distress syndrome (Related to artificial lung surfactant used for therapy)
• Stress (Related to poor diet; effect of hormones secreted under...
stressful situations that affect glucose levels)
• Syndrome X (Metabolic syndrome consisting of obesity, high blood pressure, and insulin resistance)
• Werner’s syndrome (Clinical features resemble Syndrome X)

Decreased in:
• End-stage liver disease (Related to cessation of liver function that results in decreased production of TG and TG transport proteins)
• Hyperthyroidism (Related to increased catabolism of VLDL transport proteins and general increase in metabolism)
• Hypolipoproteinemia and abetalipoproteinemia (Related to decrease in transport proteins)
• Intestinal lymphangiectasia
• Malabsorption disorders (Inadequate supply from dietary sources)
• Malnutrition (Inadequate supply from dietary sources)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs that may increase triglyceride levels include acetylsalicylic acid, aldatense, atenolol, bendroflumethiazide, cyclosporine, danazol, glucocorticoids, oral contraceptives, oxprenolol, pindolol, prazosin, propranolol, tamoxifen, and timolol.
• Drugs and substances that may decrease triglyceride levels include ascorbic acid, bezafibrate, captopril, carvedilol, celiprolol, chenodeoxycholic acid, cholestyramine, cilazapril, ciprofibrate, clofibrate, colistipol, dextrothyroxine, doxazosin, enalapril, eptastatin, fenofibrate, flaxseed oil, gemfibrozil, glucagon, halofenate, insulin, levonorgestrel, lovastatin, medroxyprogesterone, metformin, nafenoopin, niacin, niteritol, pinacidil, pindolol, pravastatin, prazosin, probucol, simvastatin, and verapamil.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate and monitor hyperlipidemia.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular and gastrointestinal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- The patient should fast for 12 hr before specimen collection. Ideally, the patient should be on a stable diet for 3 wk and avoid alcohol consumption for 3 days before specimen collection. Protocols may vary from facility to facility.
- There are no medication restrictions, unless by medical direction.

INTRATEST:
- Ensure that the patient has complied with dietary restrictions and other pretesting preparations; assure that food has been restricted for at least 12 hr prior to the procedure.
If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**
A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
Instruct the patient to resume usual diet, as directed by the HCP.
Nutritional considerations: Increased triglyceride levels may be associated with atherosclerosis and CAD. Nutritional therapy is recommended for individuals identified to be at high risk for developing CAD. If overweight, these patients should be encouraged to achieve a normal weight. The American Heart Association has Step 1 and Step 2 diets that may be helpful in achieving a goal of lowering total cholesterol and triglyceride levels. The Step 1 diet emphasizes a reduction in foods high in saturated fats and cholesterol. Red meats, eggs, and dairy products are the major sources of saturated fats and cholesterol. If triglycerides are also elevated, patients should be advised to eliminate or reduce alcohol and simple carbohydrates from their diet. The Step 2 diet recommends stricter reductions.

Sensitivity to social and cultural issues: Numerous studies point to the increased prevalence of excess body weight in American children and adolescents. Experts estimate that 25% of American children ages 6 to 11 yr are obese. The medical, social, and emotional consequences of excess body weight are significant.
Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Special attention should be given to instructing the pediatric patient and caregiver regarding health risks and weight control. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org), or the National Heart, Lung, and Blood Institute (www.nhlbi.nih.gov).
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, atrial natriuretic peptide, blood gases, BNP, calcium (total and ionized), cholesterol (total, HDL, and LDL), CT cardiac scoring, C-reactive protein, CK and isoenzymes, echocardiography, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI chest, myocardial infarct scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, and troponin.
Refer to the Cardiovascular and Gastrointestinal System tables at the back of the book for related tests by body system.
Triiodothyronine, Free

SYNONYM/ACRONYM: Free $T_3$, $FT_3$.

SPECIMEN: Serum (1 mL) collected in a red- or tiger-top tube.

REFERENCE VALUE: (Method: Immunoassay)

DESCRIPTION: Unlike the thyroid hormone thyroxine ($T_4$), most $T_3$ is converted enzymatically from $T_4$ in the tissues rather than being produced directly by the thyroid gland (see monograph titled “Thyroxine, Total”). Approximately one-third of $T_4$ is converted to $T_3$. Most $T_2$ in the serum (99.97%) is bound to thyroxine-binding globulin (TBG), prealbumin, and albumin. The remainder (0.03%) circulates as unbound or free $T_3$, which is the physiologically active form. Levels of free $T_3$ are proportional to levels of total $T_3$. The advantage of measuring free $T_3$ instead of total $T3$ is that, unlike total $T_3$ measurements, free $T_3$ levels are not affected by fluctuations in TBG levels. $T_3$ is four to five times more biologically potent than $T_4$. This hormone, along with $T_4$, is responsible for maintaining a euthyroid state. Free $T_3$ measurements are rarely required, but they are indicated in the diagnosis of $T_3$ toxicosis and when certain drugs are being administered that interfere with the conversion of $T_4$ to $T_3$.

INDICATIONS:
- Adjunctive aid to thyroid-stimulating hormone (TSH) and free $T_4$ assessment
- Assist in the diagnosis of $T_3$ toxicosis

RESULT:

**Increased in:**
- High altitude
- Hyperthyroidism

*Triiodothyronine is produced independently of stimulation by TSH*
- $T_3$ toxicosis

**Decreased in:**
- Hypothyroidism *(Thyroid hormones are not produced in sufficient quantities regardless of TSH levels)*
- Malnutrition *(Related to iodine deficiency; iodine is needed for thyroid hormone synthesis)*
- Nonthyroidal chronic diseases
- Pregnancy (late)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs that may increase free $T_3$ include acetylsalicylic acid, amiodarone, and levothyroxine.
Drugs that may decrease free $T_3$ include amiodarone, methimazole, phenytoin, propranolol, and radiographic agents.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess thyroid gland function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

**POST-TEST:**
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include adrenocorticotropic hormone, albumin, ACE, antibodies antithyroglobulin, biopsy thyroid, copper, follicle-stimulating hormone, growth hormone, luteinizing hormone, PTH, protein, RAII, thyroglobulin, TBII, thyroid scan, TSH, TSI, $T_4$, free $T_4$, $T_3$, and US thyroid.
- Refer to the Endocrine System table at the back of the book for related tests by body system.

**Troponins I and T**

**SYNONYM/ACRONYM:** Cardiac troponin, cardiac troponin I (cTnI), cardiac troponin T (cTnT).

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable. Serial sampling is highly recommended. Care must be taken to use the same type of collection container if serial measurements are to be taken.

**REFERENCE VALUE:** (Method: Enzyme immunoassay)

<table>
<thead>
<tr>
<th>Troponin</th>

</thead>
<tbody>
<tr>
<td>I</td>
<td>Less than 0.35 ng/mL</td>
</tr>
<tr>
<td>T</td>
<td>Less than 0.20 mcg/L</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Troponin is a complex of three contractile proteins that regulate the interaction of actin and myosin. Troponin C is the calcium-binding subunit; it does not have a cardiac muscle-specific subunit. Troponin I and troponin T, however, do have cardiac muscle-specific subunits. They are detectable a few hours to 7 days after the onset of symptoms of myocardial damage. Troponin I is thought to be a more specific marker of cardiac damage than troponin T. Cardiac troponin I begins to rise 2 to 6 hr after myocardial infarction (MI). It has a biphasic peak: It initially peaks at 15 to 24 hr after MI and then exhibits a lower peak after 60 to 80 hr. Cardiac troponin T levels rise 2 to 6 hr after MI and remain elevated. Both proteins return to the reference range 7 days after MI.

**Timing for Appearance and Resolution of Serum/Plasma Cardiac Markers in Acute MI**

</table>
INDICATIONS:
• Assist in establishing a diagnosis of MI
• Evaluate myocardial cell damage

RESULT:
Increased in:
Conditions that result in cardiac tissue damage; troponin is released from damaged tissue into the circulation.
• Acute MI
• Minor myocardial damage
• Myocardial damage after coronary artery bypass graft surgery or percutaneous transluminal coronary angioplasty
• Unstable angina pectoris

Decreased in: N/A

CRITICAL VALUES:
• Troponin I: Greater than 0.5 ng/mL (Initial sample only)

Note and immediately report to the health care provider (HCP) increased results and related symptoms.

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
➢ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➢ Inform the patient that the test is used to identify and monitor cardiac injury.
➢ Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
➢ Obtain a history of the patient’s cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
➢ Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

➢ Review the procedure with the patient. Inform the patient that a number of samples will be collected. Collection at time of admission, 2 to 4 hr, 6 to 8 hr, and 12 hr after admission are the minimal recommendations. Additional samples may be requested. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
➢ Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
➢ There are no food, fluid, or medication restrictions, unless by medical direction.

➢ If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
➢ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
➢ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
➢ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
➢ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
➢ A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
➢ Nutritional considerations: Increased troponin levels are associated with coronary artery disease (CAD). Nutritional therapy is recommended for individuals identified to be at high risk for developing CAD. If overweight, these patients should be encouraged
to achieve a normal weight. The American Heart Association has Step 1 and Step 2 diets that may be helpful in achieving a goal of lowering total cholesterol and triglyceride levels. The Step 1 diet emphasizes a reduction in foods high in saturated fats and cholesterol. Red meats, eggs, and dairy products are the major sources of saturated fats and cholesterol. If triglycerides are also elevated, patients should be advised to eliminate or reduce alcohol and simple carbohydrates from their diet. The Step 2 diet recommends stricter reductions.

Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, ANP, blood gases, blood pool imaging, BNP, calcium, ionized calcium, cholesterol (total, HDL, and LDL), CRP, CT cardiac scoring, CK and isoenzymes, culture viral, echocardiography, echocardiography transesophageal, ECG, exercise stress test, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI chest, MI infarct scan, myocardial perfusion heart scan, myoglobin, pericardial fluid analysis, PET heart, potassium, and triglycerides.

Refer to the Cardiovascular System table at the back of the book for related tests by body system.

---

### Tuberculin Skin Tests

**SYNONYM/ACRONYM:** TB tine test, PPD, Mantoux skin test, QuantiFERON®-TB Gold blood test (QFT-G).

**SPECIMEN:** Whole Blood (5 mL) collected in a green-top (LiHep or NaHep) tube.

**REFERENCE VALUE:** (Method: Intradermal skin test, Enzyme Linked Immunosorbent Assay (ELISA) blood test) Negative.

**DESCRIPTION:** Tuberculin skin tests are done to determine past or present exposure to tuberculosis (TB). The multipuncture or tine test, a screening technique, uses either purified protein derivative (PPD) of tuberculin or old tuberculin. A positive response at the puncture site indicates cell-mediated immunity to the...
Tubulin Skin Tests

Organism or a delayed hypersensitivity caused by interaction of the sensitized T lymphocytes. Verification of the patient’s positive response to the multipuncture test is done with the more definitive Mantoux test using Aplisol or Tubersol administered by intradermal injection. The Mantoux test is the test of choice in symptomatic patients. It is also used in some settings as a screening test. A negative result is judged if there is no sign of redness or induration at the site of the injection or if the zone of redness and induration is less than 5 mm in diameter. A positive result is evidenced by an area of erythema and induration at the injection site that is greater than 10 mm. A positive result does not distinguish between active and dormant infection. A positive response to the Mantoux test is followed up with chest radiography and bacteriological sputum testing to confirm diagnosis. The QuantiFERON®-TB Gold (QFT-G) blood test was approved by the FDA in 2005 for all applications in which the skin test is used. The blood test is a two-step procedure in which a sample of whole blood containing T-lymphocytes from the patient is incubated with a reagent cocktail of peptides known to be present in individuals infected by Mycobacterium tuberculosis, but not found in the blood of previously vaccinated individuals or individuals who do not have the disease. The blood test offers the advantage of eliminating many of the false reactions encountered with skin testing, only a single patient visit is required, and results can be available within 24 hr.

Indications:
- Evaluate cough, weight loss, fatigue, hemoptysis, and abnormal x-rays to determine if the cause of symptoms is TB
- Evaluate known or suspected exposure to TB, with or without symptoms, to determine if TB is present
- Evaluate patients with medical conditions placing them at risk for TB (e.g., AIDS, lymphoma, diabetes)
- Screen infants with the tine test at the time of first immunizations to determine TB exposure
- Screen populations at risk for developing TB (e.g., health care providers [HCPs], nursing home residents, correctional facility personnel, prison inmates, and residents of the inner city living in poor hygienic conditions)

Result:
Positive findings in:
- Pulmonary TB

Critical values:
Note and immediately report to the HCP positive results and related symptoms.

Interfering factors:
- Skin Tests:
  - Drugs such as immunosuppressive agents or steroids can alter results.
  - Diseases such as hematological cancers or sarcoidosis can alter results.
  - Recent or present bacterial, fungal, or viral infections may affect results. False-positive results may be caused by the presence of non-tuberculous mycobacteria or by serial testing.
  - False-negative results can occur if sensitized T cells are temporarily decreased. False-negative results also can occur in the presence of bacterial infections, immunological deficiencies, immunosuppressive agents, live-virus vaccinations.

Access additional resources at davisplus.fadavis.com
(e.g., measles, mumps, varicella, rubella), malnutrition, old age, overwhelming TB, renal failure, and active viral infections (e.g., chickenpox, measles, mumps).

- Improper storage of the tuberculin solution (e.g., with respect to temperature, exposure to light, and stability on opening) may affect the results.
- Improper technique when performing the intradermal injection (e.g., injecting into subcutaneous tissue) may cause false-negative results.
- Incorrect amount or dilution of antigen injected or delayed injection after drawing the antigen up into the syringe may affect the results.
- Incorrect reading of the measurement of response or timing of the reading may interfere with results.
- It is not known whether the test has teratogenic effects or reproductive implications; the test should be administered to pregnant women only when clearly indicated.
- The test should not be administered to a patient with a previously positive tuberculin skin test because of the danger of severe reaction, including vesication, ulceration, and necrosis.
- The test does not distinguish between current and past infection.

**Blood Test:**
- The QFT-G blood test has not been evaluated with patients who have impaired or altered immune function, have or have a high likelihood to develop TB, are younger than 17, are pregnant, or have diseases other than TB.

**Blood Test:**
- Inform the patient that the test is used to indicate exposure to TB.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies and sensitivities to latex.
- Obtain a history of the patient’s immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of TB or TB exposure, signs and symptoms indicating possible TB, and other skin tests or vaccinations and sensitivities.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient.

**Skin Test:**
- Ensure that the patient does not currently have TB and has not had a positive skin test previously before beginning the test. Do not administer the test if the patient has a skin rash or other eruptions at the test site. Inform the patient that the procedure takes approximately 5 min. Address concerns about pain and explain that a moderate amount of pain may be experienced when the intradermal injection is performed.
- Emphasize to the patient that the area should not be scratched or disturbed after the injection and before the reading.

**Blood Test:**
- Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

**Blood and Skin Test:**
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

**Blood and Skin Test:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

**INTRATEST:**

**Blood and Skin Test:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.

Skin Test:
Have epinephrine hydrochloride solution (1:1000) available in the event of anaphylaxis.

Cleanse the skin site on the lower anterior forearm with alcohol swabs and allow to air-dry.

Multipuncture Test:
Remove the cap covering the tines and stretch the forearm skin taut. Firmly press the device into the prepared site, hold it in place for 1 sec, and then remove it. Four punctures should be visible. Record the site, and remind the patient to return in 48 to 72 hr to have the test read. At the time of the reading, use a plastic ruler to measure the diameter of the largest indurated area, making sure the room is sufficiently lighted to perform the reading. A palpable induration greater than or equal to 2 mm at one or more of the punctures indicates a positive test result.

Mantoux (intradermal) Test:
Prepare PPD or old tuberculin in a tuberculin syringe with a short, 26-gauge needle attached. Prepare the appropriate dilution and amount for the most commonly used intermediate strength (5 tuberculin units in 0.1 mL) or a first strength usually used for children (1 tuberculin unit in 0.1 mL). Inject the preparation intradermally at the prepared site as soon as it is drawn up into the syringe. When properly injected, a bleb or wheal 6 to 10 mm in diameter is formed within the layers of the skin. Record the site, and remind the patient to return in 48 to 72 hr to have the test read. At the time of the reading, use a plastic ruler to measure the diameter of the largest indurated area, making sure the room is sufficiently lighted to perform the reading. Palpate for thickening of the tissue; a positive result is indicated by a reaction of 5 mm or more with erythema and edema.

Blood Test:
Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage. Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient. Recognize anxiety related to test results and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Counsel the patient, as appropriate, regarding the risk of transmission and proper prophylaxis, and reinforce the importance of strict adherence to the treatment regimen. Inform the patient that positive findings must be reported to local health department officials, who will question him or her regarding other persons who may have been exposed through contact. Educate the patient regarding access to counseling services.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Emphasize to the patient who receives skin testing of the need to return and have the test results read within the specified time frame of 48 to 72 hr after injection. Inform the patient that the effects from a positive response at the site can remain for 1 wk. Educate the patient that a positive result may put him or her at risk for infection.
related to impaired primary defenses, impaired gas exchange related to decrease in effective lung surface, and intolerance to activity related to an imbalance between oxygen supply and demand. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

### RELATED MONOGRAPHS:

- Related tests include alveolar/arterial gradient, angiography pulmonary, biopsy lung, blood gases, bronchoscopy, calcium, carbon dioxide, chest x-ray, complete blood count, WBC count and differential, CT thoracic, culture and smear mycobacteria, culture blood, culture sputum, cytology sputum, eosinophil count, ESR, gallium scan, gram stain, lung perfusion scan, lung ventilation scan, mediastinoscopy, pleural fluid analysis, PFT, and zinc.

- Refer to the Immune and Respiratory System tables at the back of the book for related tests by body system.

---

### Tuning Fork Tests

**SYNONYM/ACRONYM:** Bing test, Rinne test, Schwabach test, Weber test.

**AREA OF APPLICATION:** Ears.

**CONTRAST:** N/A.

**DESCRIPTION:** These noninvasive assessment procedures are done to distinguish conduction hearing loss from sensorineural hearing loss. They may be performed as part of the physical assessment examination and followed by hearing loss audiology for confirmation of questionable results. The tuning forks tests described in this monograph are named for the four German otologists who described their use. Tuning forks tests are used less frequently by audiologists in favor of more sophisticated electronic methods, but presentation of the tuning fork test methodology is useful to illustrate the principles involved in electronic test methods.

A tuning fork is a bipranged metallic device that emits a clear tone at a particular pitch when it is set into vibration by holding the stem in the hand and striking one of the prongs or tines against a firm surface. The Bing test samples for conductive hearing loss by intermittently occluding and unblocking the opening of the ear canal while holding a vibrating tuning fork to the mastoid process behind the ear. The occlusion effect is absent in patients with conductive hearing loss and is present in patients with normal hearing or with sensorineural hearing loss. The Rinne test compares the patient’s own hearing by bone conduction to his or her hearing by air conduction to determine whether hearing loss,
if detected, is conductive or sensorineural. The Schwabach test compares the patient’s level of bone conduction hearing to that of a presumed normal-hearing examiner. The Weber test has been modified by many audiologists for use with electronic equipment. When the test is administered, the patient is asked to tell the examiner the location of the tone heard (left ear, right ear, both ears, or midline) in order to determine whether the hearing loss is conductive, sensorineural, or mixed.

**INDICATIONS:**
- Evaluate type of hearing loss (conductive or sensorineural)
- Screen for hearing loss as part of a routine physical examination and to determine the need for referral to an audiologist

**RESULT:**

**Normal findings in:**
- Normal air and bone conduction in both ears. No evidence of hearing loss.
- Bing test: Pulsating sound that gets louder and softer when the opening to the ear canal is alternately opened and closed. *(Note: This result, observed in patients with normal hearing, is also observed in patients with sensorineural hearing loss.)*
- Rinne test: Longer and louder tone heard by air conduction than by bone conduction. *(Note: This result, observed in patients with normal hearing, is also observed in patients with sensorineural hearing loss.)*
- Schwabach test: Same tone loudness heard equally long by the examiner and the patient.
- Weber test: Same tone loudness heard equally in both ears.

**Abnormal findings in:**
- Conduction hearing loss:
  - Bing test: No change in the loudness of the sound.
  - Rinne test: Tone louder or detected for a longer time than the air-conducted tone
  - Schwabach test: Prolonged duration of tone when compared to that heard by the examiner
  - Weber test: Lateralization of tone to one ear indicating loss of hearing on that side (i.e., tone is heard in the poorer ear)
- Sensorineural hearing loss:
  - Bing test: Pulsating sound that gets louder and softer when the opening to the ear canal is alternately opened and closed
  - Rinne test: Tone heard louder by air conduction
  - Schwabach test: Shortened duration of tone when compared to that heard by the examiner.
  - Weber test: Lateralization of tone to one ear indicating loss of hearing on the other side (i.e., tone is heard in the better ear)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

**Factors that may impair the results of the examination:**
- Poor technique in striking the tuning fork or incorrect placement can result in inaccurate results.
- Inability of the patient to understand how to identify responses or unwillingness of the patient to cooperate during the test can cause inaccurate results.
- Hearing loss in the examiner can affect results in those tests that utilize hearing comparisons between patient and examiner.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

Access additional resources at davisplus.fadavis.com
Inform the patient that the procedure detects hearing loss.

Obtain a history of the patient’s complaints, including a list of known allergens.

Obtain a history of the patient’s known or suspected hearing loss, including type and cause; ear conditions with treatment regimens; ear surgery; and other tests and procedures to assess and diagnose auditory deficit.

Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Address concerns about pain and explain that no discomfort will be experienced during the test. Inform the patient that a health care provider (HCP) performs the test in a quiet, darkened room, and that to evaluate both ears, the test can take 5 to 10 min.

Ensure that the external auditory canal is clear of impacted cerumen.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**

- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Seat the patient in a quiet environment positioned such that the patient is comfortable and is facing the examiner. A tuning fork of 1024 Hz is used because it tests within the range of human speech (400 to 5000 Hz).
- Bing test: Tap the tuning fork handle against the hand to start a light vibration. Hold the handle to the mastoid process behind the ear while alternately opening and closing the ear canal with a finger. Ask the patient to report whether he or she hears a change in loudness or softness in sound. Record the result as a positive Bing if the patient reports a pulsating change in sound. Record as a negative Bing if no change in loudness is detected.
- Rinne test: Tap the tuning fork handle against the hand to start a light vibration. Have the patient mask the ear not being tested by moving a finger in and out of the ear canal of that ear. Hold the base of the vibrating tuning fork with the thumb and forefinger of the dominant hand and place it in contact with the patient’s mastoid process (bone conduction). Ask the patient when the sound is no longer heard. Follow this with placement of the same vibrating tuning fork in front of the ear canal (air conduction) without touching the external part of the ear. Ask the patient which of the two has the loudest or longest tone. Repeat the test in the other ear. Record as Rinne positive if air conduction is heard longer and Rinne negative if bone conduction is heard longer.
- Schwabach test: Tap the tuning fork handle against the hand to start a light vibration. Hold the base of the tuning fork against one side of the patient’s mastoid process and ask if the tone is heard. Have the patient mask the ear not being tested by moving a finger in and out of the ear canal of that ear. The examiner then places the tuning fork against the same side of his or her own mastoid process and listens for the tone. The tuning fork is alternated on the same side between patient and examiner until the sound is no longer heard, noting whether the sound ceased to be heard by both the patient and the examiner at the same point in time. The procedure is repeated on the other ear. If the patient hears the tone for a longer or shorter time, count and note this in seconds.
- Weber test: Tap the tuning fork handle against the hand to start a light vibration. Hold the base of the vibrating tuning fork with the thumb and forefinger of the dominant hand and place it on the middle of the patient’s forehead or at the vertex of the head. Ask the patient to determine if the sound is heard better and longer on one side than the other. Record as Weber right or left. If sound is heard equally, record as Weber negative.
POST-TEST:
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Recognize anxiety related to test results, and be supportive of impaired activity related to hearing loss and perceived loss of independence. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Speech-Language-Hearing Association (www.asha.org).
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. As appropriate, instruct the patient in the use, cleaning, and storing of a hearing aid. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include audiometry hearing loss, evoked brain potential studies for hearing loss, otoscopy, and spondee speech reception threshold.
- Refer to the Auditory System table at the back of the book for related tests by body system.
Ultrasound, Arterial Doppler, Carotid Studies

**SYNONYM/ACRONYM:** Carotid Doppler, carotid ultrasound, arterial ultrasound.

**AREA OF APPLICATION:** Arteries.

**CONTRAST:** Done without contrast.

**DESCRIPTION:** Ultrasound (US) procedures are diagnostic, non-invasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Using the duplex scanning method, carotid US records sound waves to obtain information about the carotid arteries. The amplitude and waveform of the carotid pulse are measured, resulting in a two-dimensional image of the artery. Carotid arterial sites used for the studies include the common carotid, external carotid, and internal carotid. Blood flow direction, velocity, and the presence of flow disturbances can be readily assessed. The sound waves hit the moving red blood cells and are reflected back to the transducer, a flashlight-shaped device, pressed against the skin. The sound that is emitted by the equipment corresponds to the velocity of the blood flow through the vessel. The result is the visualization of the artery to assist in the diagnosis (i.e., presence, amount, location) of plaque causing vessel stenosis or atherosclerotic occlusion affecting the flow of blood to the brain. Depending on the degree of stenosis causing a reduction in vessel diameter, additional testing can be performed to determine the effect of stenosis on the hemodynamic status of the artery.

**INDICATIONS:**
- Assist in the diagnosis of carotid artery occlusive disease, as evidenced by visualization of blood flow disruption
- Detect irregularities in the structure of the carotid arteries
- Detect plaque or stenosis of the carotid artery, as evidenced by turbulent blood flow or changes in Doppler signals indicating occlusion

**RESULT:**

*Normal findings in:*
- Normal blood flow through the carotid arteries with no evidence of occlusion or narrowing

*Abnormal findings in:*
- Carotid artery occlusive disease (atherosclerosis)
- Plaque or stenosis of carotid artery
- Reduction in vessel diameter of more than 16%, indicating stenosis

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

*Factors that may impair clear imaging:*
- Attenuation of the sound waves by bony structures, which can impair clear imaging of the vessels
- Incorrect placement of the transducer over the desired test site
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the arteries in the neck.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results (i.e., barium or iodine-based contrast procedures, surgery, or biopsy). There should be 24 hr between administration of barium or iodine contrast medium and this test.
- Obtain a list of the patient’s current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.
- *Sensitivity to social and cultural issues,* as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination.
- Expose the neck and drape the patient.
- Conductive gel is applied to the skin and a Doppler transducer is moved over the skin to obtain images of the area of interest.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- When the study is completed, remove the gel from the skin.
- Instruct the patient to continue with diet, fluids, and medications, as directed by the HCP.
- *Nutritional considerations:* A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address...
any concerns voiced by the patient or family.

Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include angiography carotid, angiography coronary, antiarrhythmic drugs, apolipoprotein A & B, AST, blood gases, calcium, cholesterol (total, HDL, LDL), CT angiography, CT cardiac scoring, echocardiography, CRP, CK and isoenzymes, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI angiography, MRI chest, myocardial infarction scan, myocardial perfusion heart scan, myoglobin, K, PET heart, triglycerides, and troponin.

Refer to the Cardiovascular System table in the back of the book for related tests by body system.

---

### Ultrasound, Arterial Doppler, Lower and Upper Extremity Studies

**SYNONYM/ACRONYM:** Doppler, arterial ultrasound, duplex scan.

**AREA OF APPLICATION:** Arteries of the lower and upper extremities.

**CONTRAST:** Done without contrast.

**DESCRIPTION:** Ultrasound (US) procedures are diagnostic, non-invasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Using the duplex scanning method, arterial leg US records sound waves to obtain information about the arteries of the lower extremities from the common femoral arteries and their branches as they extend into the calf area. The amplitude and waveform of the pulses are measured, resulting in a two-dimensional image of the artery. Blood flow direction, velocity, and the presence of flow disturbances can be readily assessed, and for diagnostic studies, the technique is done bilaterally. The sound waves hit the moving red blood cells and are reflected back to the transducer, a flashlight-shaped device, pressed against the skin. The sound that is emitted by the equipment corresponds to the velocity of the blood flow through the vessel. The result is the visualization of the artery to assist in the diagnosis (i.e., presence, amount, and location) of plaque causing vessel stenosis or occlusion and to help determine the cause of
claudication. Arterial reconstruction and graft condition and patency can also be evaluated.

In arterial Doppler studies, arteriosclerotic disease of the peripheral vessels can be detected by slowly deflating blood pressure cuffs that are placed on an extremity such as the calf, ankle, or upper extremity. The systolic pressure of the various arteries of the extremities can be measured. The Doppler transducer can detect the first sign of blood flow through the cuffed artery, even the most minimal blood flow, as evidenced by a swishing noise. There is normally a reduction in systolic blood pressure from the arteries of the arms to the arteries of the legs; a reduction exceeding 20 mm Hg is indicative of occlusive disease (deep vein thrombosis) proximal to the area being tested. This procedure may also be used to monitor the patency of a graft, status of previous corrective surgery, vascular status of the blood flow to a transplanted organ, blood flow to a mass, or the extent of vascular trauma.

**INDICATIONS:**
- Aid in the diagnosis of small or large vessel arterial occlusive disease
- Aid in the diagnosis of spastic arterial disease, such as Raynaud’s phenomenon
- Assist in the diagnosis of aneurysm, pseudoaneurysm, hematoma, arteriovenous malformation, or hemangioma
- Assist in the diagnosis of ischemia, arterial calcification, or plaques, as evidenced by visualization of blood flow disruption
- Detect irregularities in the structure of the arteries
- Detect plaque or stenosis of the lower extremity artery, as evidenced by turbulent blood flow or changes in Doppler signals indicating occlusion
- Determine the patency of a vascular graft, stent, or previous surgery
- Evaluate possible arterial trauma

**RESULT:**

**Normal findings in:**
- Normal blood flow through the lower extremity arteries with no evidence of vessel occlusion or narrowing
- Normal arterial systolic and diastolic Doppler signals
- Normal reduction in systolic blood pressure (i.e., less than 20 mm Hg) when compared to a normal extremity
- Normal ankle-to-brachial (AB) arterial blood pressure (ankle pressure divided by brachial pressure; normal AB pressure index is greater than 0.85)

**Abnormal findings in:**
- AB pressure index less than 0.85, indicating significant arterial occlusive disease within the extremity
- Aneurysm
- Arterial calcification or plaques
- Embolic arterial occlusion
- Graft diameter reduction
- Hemangioma
- Hematoma
- Ischemia
- Large or small vessel occlusive disease
- Pseudoaneurysm
- Reduction in vessel diameter of more than 16%, indicating stenosis
- Spastic arterial occlusive disease, such as Raynaud’s phenomenon

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

This procedure is contraindicated for:
- Patients with an open or draining lesion
Factors that may impair the results of the examination:

- Attenuation of the sound waves by bony structures, which can impair clear imaging of the vessels
- Cold extremities, resulting in vasoconstriction, which can cause inaccurate measurements
- Occlusion proximal to the site being studied, which would affect blood flow to the area
- Cigarette smoking, because nicotine can cause constriction of the peripheral vessels
- An abnormally large leg, making direct examination difficult
- Incorrect placement of the transducer over the desired test site
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

or iodine-based contrast procedures, surgery, or biopsy). There should be 24 hr between administration of barium or iodine contrast medium and this test.

- Obtain a list of the patient’s current medications including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health care provider (HCP) specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the peripheral arteries of the lower or upper extremities.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Report the presence of a lesion that is open or draining; maintain clean, dry dressing for the ulcer; protect the limb from trauma.
- Note any recent procedures that can interfere with test results (i.e., barium

**INTRATEST:**

- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination.
- Expose the area of interest and drape the patient.
- Place blood pressure cuffs on the thigh, calf, and ankle.
- Apply conductive gel to the skin over the area distal to each of the cuffs to promote the passage of sound waves as a Doppler transducer is moved over the skin to obtain images of the area of interest.
Inflate the thigh cuff to a level above the patient’s systolic pressure found in the normal extremity.
Place the Doppler transducer in the gel, distal to the inflated cuff, and slowly release the pressure in the cuff.
When the swishing sound of blood flow is heard, record it at the highest point along the artery at which it is audible. The test is repeated at the calf and then the ankle.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- When the study is completed, remove the gel from the skin.
- Instruct the patient to continue diet, fluids, and medications, as directed by the HCP.

Nutritional considerations: A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.
Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include alveolar/arterial ratio, angiography pulmonary, ANA, blood gases, complete blood count, platelet count, CT angiography, D-Dimer, FDP, fibrinogen, lung perfusion scan, lung ventilation scan, MRI abdomen, MRI angiography, aPTT, plethysmography, PT/INR, US venous Doppler lower extremities, and venography lower extremity.
- Refer to the Cardiovascular System table in the back of the book for related tests by body system.

Ultrasound, A-scan

**SYNONYM/ACRONYM:** None.

**AREA OF APPLICATION:** Eyes.

**CONTRAST:** N/A.

**DESCRIPTION:** Diagnostic techniques such as A-scan ultrasonography can be used to identify abnormal tissue. The A-scan employs a single-beam, linear sound wave to detect abnormalities by returning an echo when interference disrupts its straight path. When the sound wave is directed at lens vitreous, the normal homogeneous tissue does not return an echo; an opaque lens with a cataract will produce an echo. The returning waves detected by abnormal tissue are received by a microfilm.
that converts the sound energy into electrical impulses that are amplified and displayed on an oscilloscope as an ultrasonogram or echogram. The A-scan echo can be used to indicate the position of the cornea and retina. The A-scan is most commonly used to measure the axial length of the eye. This measurement is used to determine the power requirement for an intraocular lens used to replace the abnormal, opaque lens of the eye removed in cataract surgery. There are two different methods currently in use. The applanation method involves placement of an ultrasound (US) probe directly on the cornea. The immersion technique is more popular because it does not require direct contact and compression of the cornea. The immersion technique protects the cornea by placement of a fluid layer between the eye and the US probe. The accuracy of the immersion technique is thought to be greater than applanation because no corneal compression is caused by the immersion method. Therefore, the measured axial length achieved by immersion is closer to the true axial length of the cornea.

**INTERFERING FACTORS:**

*Factors that may impair the results of the examination:*

- Inability of the patient to cooperate and remain still during the procedure may interfere with the test results.
- Rubbing or squeezing the eyes may affect results.
- Improper placement of the probe tip to the surface of the eye may produce inaccurate results.

**INDICATIONS:**

- Determination of power requirement for replacement intraocular lens in cataract surgery.

**RESULT:**

*Normal findings in:*

- Normal homogeneous ocular tissue

*Abnormal findings in:*

- Cataract

**CRITICAL VALUES:** N/A

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure determines the strength of the lens that will be replaced during cataract surgery.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially topical anesthetic eyedrops.
- Obtain a history of the patient’s known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Instruct the patient to remove contact lenses or glasses, as appropriate.
- Instruct the patient regarding the importance of keeping the eyes open for the test.
- Review the procedure with the patient. Explain that the patient will be requested to fixate the eyes during the procedure. Address concerns
about pain and explain that no dis-
comfort will be experienced during the test but that some discomfort may be experienced after the test when the numbness wears off from the anesthetic drops administered prior to the test. Inform the patient that a health care provider (HCP) performs the test, in a quiet, dark-
eden room, and that evaluation of the eye upon which surgery is to be performed can take up 10 min.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is impor-
tant in providing psychological support before, during, and after the procedure.

There are no food, fluid or medication restrictions, unless by medical direction.

**INTRATEST:**

- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- Seat the patient comfortably. Instruct the patient to look straight ahead, keeping the eyes open and unblinking.
- Instill topical anesthetic in each eye, as ordered, and provide time for it to work. Topical anesthetic drops are placed in the eye with the patient looking up and the solution directed at the six o’clock position of the sclera (white of the eye) near the limbus (grey, semitransparent area of the eyeball where the cornea and sclera meet). Neither the dropper nor the bottle should touch the eyelashes.
- Ask the patient to place the chin in the chin rest and gently press the forehead against the support bar. When the US probe is properly positioned on the patient’s surgical eye, a reading is automatically taken.
- Multiple measurements may be taken in order to ensure that a consistent and accurate reading has been achieved. Variability between serial measurements is unavoidable using the applanation technique.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Recognize anxiety related to test results. Encourage the patient to rec-
ognize and be supportive of impaired activity related to vision loss, antici-
pated loss of driving privileges, or the possibility of requiring corrective lenses (self-image). Discuss the implications of test results on the patient’s lifestyle. Reassure the patient regard-
ing concerns related to the impending cataract surgery. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor pro-
gression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Refer to the Ocular System table at the back of the book for related tests by body system.
Ultrasound, Biophysical Profile, Obstetric

SYNONYM/ACRONYM: BPP ultrasound, OB sonography, fetal age sonogram, gestational age sonogram, pregnancy ultrasound, pregnancy echo, pregnant uterus ultrasonography.

AREA OF APPLICATION: Pelvis and abdominal region.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, non-invasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Obstetric US uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin or inserted into the vagina. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to visualize the fetus and placenta. This procedure is done by a transabdominal or transvaginal approach, depending on when the procedure is performed (first trimester [transvaginal] vs. second trimester [transabdominal]). It is the safest method of examination to evaluate the uterus and determine fetal size, growth, and position; fetal structural abnormalities; ectopic pregnancy; placenta position and amount of amniotic fluid; and multiple gestation. Obstetric US is used to secure different types of information regarding the fetus, varying with the trimester during which the procedure is done. This procedure may also include a nonstress test (NST) in combination with Doppler monitoring of amniotic fluid volume, fetal heart, gross fetal movements, fetal muscle tone, and fetal respiratory movements to detect high-risk pregnancy.

The procedure is indicated as a guide for amniocentesis, cordocentesis, fetoscopy, aspiration of multiple oocytes for in vitro fertilization, and other intrauterine interventional procedures. Because the pregnant uterus is filled with amniotic fluid, ultrasonography is an ideal method of evaluating the fetus and placenta; it is also the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures.

The biophysical profile (BPP) is a grouping of five antepartum parameters measured to predict fetal wellness. This test grouping is indicated in women with high-risk pregnancies to identify a fetus in distress or in jeopardy of demise. The BPP includes the measurement of fetal heart rate (FHR), fetal breathing movements, fetal body movements, fetal muscle tone, and amniotic fluid volume. Each of the five parameters is
assigned a score of either 0 or 2, allowing a maximum or perfect score of 10. The NST is an external US monitoring of FHR either performed as part of the

BPP or when one or more of the US procedures have abnormal results. The NST is interpreted as either reactive or nonreactive.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Normal: Score = 2</th>
<th>Abnormal: Score = 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fetal Heart Rate Reactivity</td>
<td>Two or more movement-associated FHR accelerations of 15 or more beats/min above baseline, lasting 15 seconds, in a 20-min interval</td>
<td>One or no movement-associated FHR accelerations of 15 or more beats/min above baseline, in a 20-min interval</td>
</tr>
<tr>
<td>Fetal Breathing Movements</td>
<td>One or more breathing movements lasting 20–60 sec in a 30-min interval</td>
<td>Absent or no breathing movements lasting longer than 19 sec in a 30-min interval</td>
</tr>
<tr>
<td>Fetal Body Movements</td>
<td>Two or more discrete body or limb movements in a 30-min interval</td>
<td>Less than two discrete body or limb movements in a 30-min interval</td>
</tr>
<tr>
<td>Fetal Muscle Tone</td>
<td>One or more episodes of active limb extension and return to flexion (to include opening and closing of hand)</td>
<td>Absent movement, slow extension with partial return to flexion, partial opening of hand</td>

<tr>
<td>Amniotic Fluid Volume</td>
<td>One or more pockets of fluid that are 2 or more cm in the vertical axis</td>
<td>No pockets of fluid or no pocket measuring at least 2 cm in the vertical axis</td>
</tr>
</tbody>
</table>

A contraction stress test (CST or oxytocin challenge test) may be requested in the event of an abnormal fetal heart rate in the BPP or NST. The CST is used to assess the fetus’s ability to tolerate low oxygen levels as experienced during labor contractions. The CST includes external FHR monitoring by US and measurement of oxytocin (pitocin)-induced uterine contractions. Pressure changes during contractions are monitored on an external tocodynamometer. Results of the two tests are interpreted as negative or positive. A negative or normal finding is no late decelerations of FHR during three induced contractions over a 10 min period. A positive or abnormal finding is identified when frequent contractions of 90 sec or more occur and FHR decelerates beyond the time of the contractions. The amniotic fluid index (AFI) is another application of US used to estimate amniotic fluid volume. The abdomen is divided into four quadrants using the umbilicus to delineate upper and lower halves and linea nigra to delineate the left and right halves. The numbered score is determined by adding the sum in centimeters of fluid in pockets seen in each of the four quadrants. The score is interpreted in relation to gestational age. The median index is considered normal between
8–12 cm. Oligohydramnios (too little amniotic fluid) is associated with an index between 5–6 cm, and polyhydramnios (too much amniotic fluid) with an index between 18–22 cm.

**INDICATIONS:**
- Detect blighted ovum (missed abortion), as evidenced by empty gestational sac
- Detect fetal death, as evidenced by absence of movement and fetal heart tones
- Detect fetal position before birth, such as breech or transverse presentations
- Detect tubal and other forms of ectopic pregnancy
- Determine and confirm pregnancy or multiple gestation by determining the number of gestational sacs in the first trimester
- Determine cause of bleeding, such as placenta previa or abruptio placentae
- Determine fetal effects of Rh incompatibility due to maternal sensitization
- Determine fetal gestational age by uterine size and measurements of crown-rump length, biparietal diameter, fetal extremities, head, and other parts of the anatomy at key phases of fetal development
- Determine fetal heart and body movements and detect high-risk pregnancy by monitoring fetal heart and respiratory movements in combination with Doppler US or real-time gray-scale scanning
- Determine fetal structural anomalies, usually at the 20th week of gestation or later
- Determine the placental size, location, and site of implantation
- Differentiate a tumor (hydatidiform mole) from a normal pregnancy
- Guide the needle during amniocentesis and fetal transfusion
- Measure fetal gestational age and evaluate umbilical artery, uterine artery, and fetal aorta by Doppler examination to determine fetal intrauterine growth retardation
- Monitor placental growth and amniotic fluid volume

**RESULT:**

**Normal findings in:**
- Normal age, size, viability, position, and functional capacities of the fetus
- Normal placenta size, position, and structure; adequate volume of amniotic fluid
- BPP score of 8–10 is considered normal. Each of the fetal movements evaluated in the BPP is related to oxygen-dependent activities that originate from the central nervous system. Their presence is assumed to indicate normal brain function and absence of systemic hypoxia.

**Abnormal findings in:**
- Abruptio placentae
- Adnexal torsion
- Cardiac abnormalities
- Ectopic pregnancy
- Fetal death
- Fetal hydrops
- Fetal malpresentation (breech, transverse)
- Hydrocephalus
- Intestinal atresia
- Myelomeningocele
- Multiple pregnancy
- Placenta previa
- Renal or skeletal defects
- BPP score between 4 and 6 is considered equivocal. Gestational age is important in determining intervals for retesting and/or a decision to deliver.

**CRITICAL VALUES:**
- Abruptio placentae
- Adnexal torsion
- BPP score between 0 and 2 is abnormal and indicates the need for assessment and immediate delivery.
- Ectopic pregnancy
- Fetal death
- Placenta previa
Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients with latex allergy; use of the vaginal probe requires the probe to be covered with a condom-like sac, usually made from latex. Some covers that are latex-free are available.

Factors that may impair clear imaging:
- Incorrect placement of the transducer over the desired test site
- Retained gas or barium from a previous radiological procedure
- Dehydration, which can cause failure to demonstrate the boundaries between organs and tissue structures
- Insufficiently full bladder, which fails to push the bowel from the pelvis and the uterus from the symphysis pubis, thereby prohibiting clear imaging of the pelvic organs in transabdominal imaging
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Improper adjustment of the US equipment to accommodate obese or thin patients, which can cause a poor-quality study
- Patients who are very obese, who may exceed the weight limit for the equipment

Factors that may result in incorrect values:
- Absence of activity in a particular parameter of the BPP may be related to fetal sleep pattern; gestational age less than 33 wk or greater than 42 wk; maternal ingestion of glucose; nicotine; or alcohol; maternal administration of magnesium or medications; artificial or premature rupture of membranes; and/or labor.

Other considerations:
- Inability of the patient to cooperate or remain still during the procedure because of significant pain or mental status may interfere with the test results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses abdomen and pelvic organ function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of results of the patient’s reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
- Endoscopic retrograde cholangiopancreatography and colonoscopy, if ordered, should be scheduled after this procedure.
- Record the date of the last menstrual period. Obtain a history of menstrual dates, previous pregnancy, and treatment received for high-risk pregnancy.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient the procedure is performed in a US department, usually by a health...
care provider (HCP) specializing in this procedure, and takes approximately 30 to 60 min. For the transvaginal approach, inform the patient that a sterile latex- or sheath-covered probe will be inserted into the vagina.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient receiving transabdominal US to drink five to six glasses of fluid 90 min before the procedure, and not to void, because the procedure requires a full bladder. Patients receiving transvaginal US only do not need to have a full bladder.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.

There are no food or medications restrictions unless by medical direction. The test may be scheduled in relation to mealtime since fetal activity is highest 1 to 3 hr after the mother ingests a meal.

**INTRATEST:**

- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Ensure that the patient drank five to six glasses of fluid and has not voided, if receiving a transabdominal US.
- Instruct the patient to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table. The right- or left-side-up position may be used to allow gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- Expose the abdominal area and drape the patient.

**Transabdominal approach:** Conductive gel is applied to the skin, and a transducer is moved over the skin while the bladder is distended to obtain images of the area of interest.

**Transvaginal approach:** A lubricated, covered probe is inserted into the vagina and moved to different levels to obtain images.

Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold her breath.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Allow the patient to void, as needed.
- When the study is completed, remove the gel from the skin.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Encourage the family to seek appropriate counseling if concerned with pregnancy termination, and to seek genetic counseling if a chromosomal abnormality is determined. Decisions regarding elective abortion should take place in the presence of both parents. Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks and difficulties of delivering and raising a developmentally challenged infant, as well as exploring other options (termination of pregnancy or adoption). It is also important to discuss problems the mother and father may experience (guilt, depression, anger) if fetal abnormalities are detected.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation...
Ultrasound, Bladder

SYNONYM/ACRONYM: Bladder sonography.

AREA OF APPLICATION: Bladder.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Bladder US evaluates disorders of the bladder, such as masses or lesions. Bladder position, structure, and size are examined with the use of high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. Methods for imaging include the transrectal, transurethral, and transvaginal approach. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to evaluate the structure and position of the contents of the bladder. The examination is helpful for monitoring patient response to therapy for bladder disease. Bladder images can be included in ultrasonography of the kidneys, ureters, bladder, urethra, and gonads in diagnosing renal/neurological disorders. Bladder US may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures.

INDICATIONS:
• Assess residual urine after voiding to diagnose urinary tract obstruction causing overdistention
• Detect tumor of the bladder wall or pelvis, as evidenced by distorted position or changes in bladder contour
• Determine end-stage malignancy of the bladder caused by extension of a primary tumor of the ovary or other pelvic organ
• Evaluate the cause of urinary tract infection, urine retention, and flank pain
• Evaluate hematuria, urinary frequency, dysuria, and suprapubic pain
• Measure urinary bladder volume by transurethral or transvaginal approach

RELATED MONOGRAPHS:
Related tests include α₁-fetoprotein, amniotic fluid analysis, biopsy chorionic villus, chromosome analysis, fetal fibronectin, KUB, HCG study, Kleihauer-Betke, L/S ratio, and MRI abdomen. Refer to the Reproductive System table at the back of the book for related tests by body system.
RESULT:

Normal findings in:
• Normal size, position, and contour of the bladder

Abnormal findings in:
• Bladder diverticulum
• Cyst
• Cystitis
• Malignancy of the bladder
• Tumor
• Ureterocele
• Urinary tract obstruction

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with latex allergy; use of the vaginal probe requires the probe to be covered with a condom-like sac, usually made from latex. Some covers that are latex-free are available.

Factors that may impair clear imaging:
• Incorrect placement of the transducer over the desired test site
• Retained gas or barium from a previous radiological procedure
• Dehydration, which can cause failure to demonstrate the boundaries between organs and tissue structures
• Insufficiently full bladder, which fails to push the bowel from the pelvis and the uterus from the symphysis pubis, thereby prohibiting clear imaging of the pelvic organs in transabdominal imaging
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

Other considerations:
• Failure to follow pretesting preparations may cause the procedure to be canceled or repeated.
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses the bladder and pelvic organs.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s genitourinary, reproductive, and gastrointestinal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
• Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography of the abdomen, if ordered, should be scheduled after this procedure.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health care provider (HCP), with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is
important in providing psychological support before, during, and after the procedure.
Inform the patient for the transvaginal approach, that a sterile latex- or sheath-covered probe will be inserted into the vagina.
Instruct the patient receiving transabdominal US to drink five to six glasses of fluid 90 min before the procedure, and not to void, because the procedure requires a full bladder. Patients receiving transvaginal US only do not need to have a full bladder.
Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Ensure that the patient drank five to six glasses of fluid and has not voided, if receiving a transabdominal US.
- Instruct the patient to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table. The right- or left-side-up positions may be used to allow gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- Expose the abdominal area and drape the patient.

**Transabdominal approach:** Conductive gel is applied to the skin, and a transducer is moved over the skin while the bladder is distended to obtain images of the area of interest.

**Transvaginal approach:** A covered and lubricated probe is inserted into the vagina and moved to different levels during scanning.
Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
If the patient is to be examined for residual urine volume, ask the patient to empty the bladder; repeat the procedure and calculate the volume.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Allow the patient to void, as needed.
- When the study is completed, remove the gel from the skin.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
- Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include bladder cancer markers urine, CT pelvis, cystoscopy, IVP, KUB study, and MRI pelvis.
- Refer to the Genitourinary, Reproductive, and Gastrointestinal System tables in the back of the book for related tests by body system.
**Ultrasound, Breast**

**SYNONYM/ACRONYM:** Mammographic ultrasound.

**AREA OF APPLICATION:** Breast.

**CONTRAST:** Done without contrast.

**DESCRIPTION:** Ultrasound (US) procedures are diagnostic, non-invasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. When used in conjunction with mammography and clinical examination, breast US is indispensable in the diagnosis and management of benign and malignant process. Both breasts are usually examined during this procedure. The examination uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to determine the presence of palpable and nonpalpable masses and their size and structure. This procedure is useful in patients with an abnormal mass on a mammogram because it can determine whether the abnormality is cystic or solid; that is, it can differentiate between a palpable, fluid-filled cyst and a palpable, solid breast lesion (benign or malignant). It is especially useful in patients with dense breast tissue and in those with silicone prostheses, because the US beam easily penetrates in these situations, allowing routine examination that cannot be performed with x-ray mammography. The procedure can be done as an adjunct to mammography, or it can be done in place of mammography in patients who refuse x-ray exposure or those in whom it is contraindicated (e.g., pregnant women, women less than 25 y.o.). The procedure is indicated as a guide for biopsy and other interventional procedures and as a means of monitoring disease progression or the effects of treatment.

**INDICATIONS:**
- Detect very small tumors in combination with mammography for diagnostic validation
- Determine the presence of nonpalpable abnormalities viewed on mammography of dense breast tissue, and monitor changes in these abnormalities
- Differentiate among types of breast masses (e.g., cyst, solid tumor, other lesions) in dense breast tissue
- Evaluate palpable masses in young (less than age 25), pregnant, and lactating patients
- Guide interventional procedures such as cyst aspiration, large-needle core biopsy, fine-needle aspiration biopsy, abscess drainage, presurgical localization, and galactography
- Identify an abscess in a patient with mastitis
RESULT:

Normal findings in:
• Normal subcutaneous, mammary, and retromammary layers of tissue in both breasts; no evidence of pathological lesions (cyst or tumor) in either breast

Abnormal findings in:
• Abscess
• Breast solid tumor, lesions
• Cancer (ductal carcinoma, infiltrating lobular carcinoma, medullary carcinoma, tubular carcinoma, and papillary carcinoma)
• Cystic breast disease
• Fibroadenoma
• Focal fibrosis
• Galactocele
• Hamartoma (fibroadenolipoma)
• Hematoma
• Papilloma
• Phyllodes tumor
• Radial scar

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair clear imaging:
• Incorrect placement of the transducer over the desired test site
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
• Excessively large breasts
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

Inform the patient that the procedure assesses the breast.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of results of the patient’s reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• Instruct the patient not to apply lotions, bath powder, or other substances to the chest and breast area before the examination.
• Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
• There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
• Ensure that the patient has not applied lotions, bath powder, or other substances to the chest and breast area before the examination.
• Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
• Instruct the patient to change into the gown and robe provided.
• Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
Observe standard precautions, and follow the general guidelines in Appendix A.
Place the patient in the supine position on an exam table. The right- and left-side-up positions are also used during the scan to facilitate better organ visualization.
Expose the breast area and drape the patient.
Conductive gel is applied to the skin and a transducer is moved over the skin to obtain images of the area of interest.
Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold her breath.

POST-TEST:
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
When the study is completed, remove the gel from the skin.
Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
Related tests include biopsy breast, CEA and cancer antigens, chest x-ray, CT thorax, mammogram, MRI breast, and stereotactic biopsy breast.
Refer to the Reproductive System table at the back of the book for related tests by body system.

Ultrasound, Kidney

SYNONYM/ACRONYM: Renal ultrasound, renal sonography.

AREA OF APPLICATION: Kidney.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Renal US is used to evaluate renal system disorders. It is valuable for determining the internal components of renal masses (solid versus cystic) and for evaluating other renal diseases, renal parenchyma, perirenal tissues, and obstruction. US uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back, converted to electrical energy,
amplified by the transducer, and displayed on a monitor to evaluate the structure, size, and position of the kidney. Renal US can be performed on the same day as a radionuclide scan or other radiological procedure, and is especially valuable in patients who are in renal failure, have hypersensitivity to contrast medium, have a kidney that did not visualize on intravenous pyelography (IVP), or are pregnant. It does not rely on renal function or the injection of contrast medium to obtain a diagnosis. The procedure is indicated for evaluation after a kidney transplant and is used as a guide for biopsy and other interventional procedures, abscess drainage, and nephrostomy tube placement. Renal US may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures.

**INDICATIONS:**
- Aid in the diagnosis of the effect of chronic glomerulonephritis and end-stage chronic renal failure on the kidneys (e.g., decrease in size)
- Detect an accumulation of fluid in the kidney caused by backflow of urine, hemorrhage, or perirenal fluid
- Detect masses and differentiate between cysts or solid tumors, as evidenced by specific waveform patterns or absence of sound waves
- Determine the presence and location of renal or ureteral calculi and obstruction
- Determine the size, shape, and position of a nonfunctioning kidney to identify the cause

- Evaluate or plan therapy for renal tumors
- Evaluate renal transplantation for changes in kidney size
- Locate the site of and guide percutaneous renal biopsy, aspiration needle insertion, or nephrostomy tube insertion
- Monitor kidney development in children when renal disease has been diagnosed
- Provide the location and size of renal masses in patients who are unable to undergo IVP because of poor renal function or an allergy to iodinated contrast medium

**RESULT:**

**Normal findings in:**
- Absence of calculi, cysts, hydronephrosis, obstruction, or tumor
- Normal size, position, and shape of the kidneys and associated structures

**Abnormal findings in:**
- Acute glomerulonephritis
- Acute pyelonephritis
- Congenital anomalies, such as absent, horseshoe, ectopic, or duplicated kidney
- Hydronephrosis
- Obstruction of ureters
- Perirenal abscess or hematoma
- Polycystic kidney
- Rejection of renal transplant
- Renal calculi
- Renal cysts, hypertrophy, or tumors
- Ureteral obstruction

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

*Factors that may impair clear imaging:*
- Attenuation of the sound waves by the ribs, which can impair clear imaging of the kidney
- Incorrect placement of the transducer over the desired test site
• Retained gas or barium from a previous radiological procedure
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

Other considerations:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses kidney function.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
• Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography of the abdomen, if ordered, should be scheduled after this procedure.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department, usually by a healthcare provider (HCP), with support staff, and takes approximately 30 to 60 min.
• Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
• There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
• Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
• Instruct the patient to void and change into the gown, robe, and foot coverings provided.
• Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
• Observe standard precautions, and follow the general guidelines in Appendix A.
• Place the patient in the supine position on an exam table. The right- or left-side-up positions may be used to allow gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
• Expose the abdominal and kidney area and drape the patient.
• Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest.
• Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.

POST-TEST:
• A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
• When the study is completed, remove the gel from the skin.
• Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Ultrasound, Liver and Biliary System

SYNONYM/ACRONYM: Gallbladder ultrasound, liver ultrasound, hepatobiliary sonography.

AREA OF APPLICATION: Liver, gallbladder, bile ducts.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, non-invasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Hepatobiliary US uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to evaluate the structure, size, and position of the liver and gallbladder in the right upper quadrant (RUQ) of the abdomen. The gallbladder and biliary system collect, store, concentrate, and transport bile to the intestines to aid in digestion. This procedure allows visualization of the gallbladder and bile ducts when the patient may have impaired liver function, and it is especially helpful when done on patients in whom gallstones cannot be visualized with oral or IV radiological studies. Liver US can be done in combination with a nuclear scan to obtain information about liver function and density differences in the liver. The procedure is indicated as a guide for biopsy and other interventional procedures. Hepatobiliary US may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures.
INDICATIONS:
- Detect cysts, polyps, hematoma, abscesses, hemangioma, adenoma, metastatic disease, hepatitis, or solid tumor of the liver or gallbladder, as evidenced by echoes specific to tissue density and sharply or poorly defined masses
- Detect gallstones or inflammation when oral cholecystography is inconclusive
- Detect hepatic lesions, as evidenced by density differences and echo-pattern changes
- Determine the cause of unexplained hepatomegaly and abnormal liver function tests
- Determine cause of unexplained RUQ pain
- Determine patency and diameter of the hepatic duct for dilation or obstruction
- Differentiate between obstructive and nonobstructive jaundice by determining the cause
- Evaluate response to therapy for tumor, as evidenced by a decrease in size of the organ
- Guide biopsy or tube placement
- Guide catheter placement into the gallbladder for stone dissolution and gallbladder fragmentation

RESULT:
Normal findings in:
- Normal size, position, and shape of the liver and gallbladder, as well as patency of the cystic and common bile ducts

Abnormal findings in:
- Biliary or hepatic duct obstruction/dilation
- Cirrhosis
- Gallbladder inflammation, stones, carcinoma, polyps
- Hematoma or trauma
- Hepatic tumors, metastasis, cysts, hemangioma, hepatitis
- Hepatocellular disease, adenoma
- Hepatomegaly
- Intrahepatic abscess
- Subphrenic abscesses

CRITICAL VALUES: N/A

INTERFERING FACTORS:
Factors that may impair clear imaging:
- Attenuation of the sound waves by the ribs, which can impair clear imaging of the right lobe of the liver
- Incorrect placement of the transducer over the desired test site
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and can produce unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations:
- Failure to follow dietary restrictions may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the liver and biliary function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hepatobiliary and gastrointestinal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.

Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography of the abdomen, if ordered, should be scheduled after this procedure.

Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department, usually by a health care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

The patient should fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility.

Ensure that food and fluids have been restricted for at least 8 hr prior to the procedure.

Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.

Instruct the patient to void and change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Place the patient in the supine position on an exam table. The right- or left-side-up positions may be used to allow gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.

Expose the abdominal area and drape the patient.

Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest.

Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

When the study is completed, remove the gel from the skin.

Instruct the patient to resume usual diet and fluids, as directed by the HCP.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

Related tests include ALP, ALT, AST, bilirubin, biopsy liver, cholangiography, colonoscopy, CT abdomen, endoscopy, ERC, GGt, haptoglobin, hepatitis A, B, C (antigens and/or antibodies), hepatobiliary scan, laparoscopy abdominal, MRI abdomen, and radiofrequency ablation liver.

Refer to the Hepatobiliary and Gastrointestinal System tables at the back of the book for related tests by body system.
Ultrasound, Lymph Nodes and Retroperitoneum

SYNONYM/ACRONYM: Lymph node sonography.

AREA OF APPLICATION: Abdomen, pelvis, and retroperitoneum.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Lymph node US uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to evaluate the structure, size, and position of the lymph nodes to examine the retroperitoneum and surrounding tissues. This procedure is used for the evaluation of retroperitoneal pathology, usually lymph node enlargement. US is the preferred diagnostic method because this area is inaccessible to conventional radiography in diagnosing lymphadenopathy, although it can be used in combination with lymphangiography, magnetic resonance imaging (MRI), and computed tomography (CT) to confirm the diagnosis. The procedure may be used for monitoring the effect of radiation or chemotherapy on the lymph nodes. Lymph node US may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures.

INDICATIONS:
• Detect lymphoma
• Determine the location of enlarged nodes to plan radiation and other therapy
• Determine the size or enlargement of aortic and iliac lymph nodes
• Evaluate the effects of medical, radiation, or surgical therapy on the size of nodes or tumors, as evidenced by shrinkage or continued presence of the mass or nodes

RESULT:
Normal findings in:
• Normal retroperitoneal and intrapelvic node size of 1.5 cm in diameter

Abnormal findings in:
• Infection or abscess
• Lymphoma
• Retroperitoneal tumor

CRITICAL VALUES: N/A

INTERFERING FACTORS:
Factors that may impair clear imaging:
• Incorrect placement of the transducer over the desired test site
• Gas or feces in the gastrointestinal (GI) tract resulting from inadequate
cleansing or failure to restrict food intake before the study  
• Retained barium from a previous radiological procedure  
• Dehydration, which can cause failure to demonstrate the boundaries between organs and tissue structures  
• Insufficiently full bladder, which fails to push the bowel from the pelvis and the uterus from the symphysis pubis, thereby prohibiting clear imaging of the pelvic organs in transabdominal imaging  
• Metallic objects (e.g., jewelry, or body rings) within the examination field which may inhibit organ visualization and cause unclear images

Other considerations:  
• Failure to follow dietary/fluid instructions and other pretesting preparations may cause the procedure to be canceled or repeated.  
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**  
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.  
- Inform the patient that the procedure assesses the lymph nodes and retroperitoneum.  
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.  
- Obtain a history of the patient’s genitourinary, reproductive, immune, and GI systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.  
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.  
- Endoscopic retrograde cholangiopancreatograph, colonoscopy, and CT of the abdomen, if ordered, should be scheduled after this procedure.  
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.  
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.  
- **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.  
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.  
- The patient should fast and restrict fluids for 8 hr prior to the procedure. Inform the patient that transabdominal US requires a full bladder. Protocols may vary from facility to facility.  
- Instruct the patient to drink five to six glasses of fluid 90 min before the procedure, and not to void before the procedure.

**INTRATEST:**  
- Ensure that food and fluids have been restricted for at least 8 hr prior to the procedure.  
- Ensure that the patient drank five to six glasses of fluid 90 min before the procedure, and remind him or her not to void before the procedure.  
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.  
- Instruct the patient to change into the gown, robe, and foot coverings provided.  
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.  
- Observe standard precautions, and follow the general guidelines in Appendix A.
Place the patient in the supine position on an exam table; other positions may be used during the examination. Expose the abdominal area and drape the patient. Conductive gel is applied to the skin, and a transducer is moved over the skin while the bladder is distended to obtain images of the area of interest. Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.

**POST-TEST:**
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient. Allow the patient to void, as needed. When the study is completed, remove the gel from the skin. Instruct the patient to resume usual diet and fluids, as directed by the HCP. Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

**RELATED MONOGRAPHS:**
Related tests include angiography of the abdomen, biopsy bone marrow, biopsy lymph nodes, complete blood count, complete blood count, hemoglobin, complete blood count, RBC count, complete blood count, RBC morphology and inclusions, CT abdomen, CT colonoscopy, ESR, gallium scan, KUB study, laparoscopy abdominal, lymphangiogram, and MRI abdomen. Refer to the Genitourinary, Reproductive, Immune, and Gastrointestinal System tables at the back of the book for related tests by body system.

---

**Ultrasound, Pancreas**

**SYNONYM/ACRONYM:** Pancreatic ultrasonography.

**AREA OF APPLICATION:** Pancreas and upper abdomen.

**CONTRAST:** Done without contrast.

**DESCRIPTION:** Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Pancreatic US uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to determine the size, shape, and position of the pancreas; determine the presence of masses or other abnormalities of the pancreas; and examine the surrounding visceras. The procedure is indicated as a guide for biopsy, aspiration, and other interventional
procedures. Pancreatic US may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures; however, it is usually done in combination with computed tomography (CT) or magnetic resonance imaging of the pancreas.

**INDICATIONS:**
- Detect anatomic abnormalities as a consequence of pancreatitis
- Detect pancreatic cancer, as evidenced by a poorly defined mass or a mass in the head of the pancreas that obstructs the pancreatic duct
- Detect pancreatitis, as evidenced by pancreatic enlargement with increased echoes
- Detect pseudocysts, as evidenced by a well-defined mass with absence of echoes from the interior
- Monitor therapeutic response to tumor treatment
- Provide guidance for percutaneous aspiration and fine-needle biopsy of the pancreas

**RESULT:**

*Normal findings in:*
- Normal size, position, contour, and texture of the pancreas

*Abnormal findings in:*
- Acute pancreatitis
- Calculi
- Pancreatic duct obstruction
- Pancreatic tumor
- Pseudocysts

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

*Factors that may impair clear imaging:*
- Attenuation of the sound waves by the ribs, which can impair clear imaging of the pancreas
- Incorrect placement of the transducer over the desired test site
- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

*Other considerations:*
- Failure to follow dietary and fluids restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses pancreatic function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine and GI systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
- Endoscopic retrograde cholangiopancreatography, colonoscopy, and CT of the abdomen, if ordered, should be scheduled after this procedure.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Access additional resources at davisplus.fadavis.com
Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.

Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department, usually by a health care provider (HCP) specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

The patient should fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility.

**INTRATEST:**

- Ensure that food and fluids have been restricted for at least 8 hr prior to the procedure.
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table. The right- or left-side-up position may be used to allow gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.

- Expose the abdominal area and drape the patient.
- Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- When the study is completed, remove the gel from the skin.
- Instruct the patient to resume usual diet and fluids, as directed by the HCP.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
- Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include amylase, CEA and cancer antigens, ERCP, CT abdomen and pancreas, C peptide, KUB study, laparoscopy abdominal, lipase, MRI abdomen and pancreas, and peritoneal fluid analysis.
- Refer to the Endocrine and Gastrointestinal System tables at the back of the book for related tests by body system.
**Ultrasound, Pelvis (Gynecologic, Nonobstetric)**

**SYNONYM/ACRONYM:** Pelvic sonography, lower abdominal ultrasound, pelvic gynecologic (GYN) sonogram.

**AREA OF APPLICATION:** Pelvis and appendix region.

**CONTRAST:** Done without contrast.

**DESCRIPTION:** Ultrasound (US) procedures are diagnostic, non-invasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Gynecologic US uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin or inserted into the vagina. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor in order to:

- Determine the presence, size, and structure of masses and cysts; and
- Determine the position of an intrauterine contraceptive device (IUD)

Evaluate postmenopausal bleeding
Examine other abnormalities of the uterus, ovaries, fallopian tubes, and vagina

This procedure is done by a transabdominal or transvaginal approach. The transabdominal approach provides a view of the pelvic organs posterior to the bladder. It requires a full bladder, thereby allowing a window for transmission of the US waves, pushing the uterus away from the pubic symphysis, pushing the bowel out of the pelvis, and acting as a reference for comparison in the evaluation of the internal structures of a mass or cyst being examined. The transvaginal approach focuses on the female reproductive organs and is often used to monitor ovulation over a period of days in patients undergoing fertility assessment. This approach is also used in obese patients or in patients with retroversion of the uterus because the sound waves are better able to reach the organ from the vaginal site. Transvaginal images are significantly more accurate compared to anterior transabdominal images in identifying paracervical, endometrial, and ovarian pathology, and the transvaginal approach does not require a full bladder. The procedure is indicated as a guide for biopsy and other interventional procedures. Pelvic US may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures.

**INDICATIONS:**
- Detect and monitor the treatment of pelvic inflammatory disease (PID) when done in combination with other laboratory tests
- Detect bleeding into the pelvis resulting from trauma to the area or ascites associated with tumor metastasis

Access additional resources at davisplus.fadavis.com
- Detect masses in the pelvis and differentiate them from cysts or solid tumors, as evidenced by differences in sound-wave patterns
- Detect pelvic abscess or peritonitis caused by a ruptured appendix or diverticulitis
- Detect pregnancy, including ectopic pregnancy
- Detect the presence of ovarian cysts and malignancy and determine the type, if possible, as evidenced by size, outline, and change in position of other pelvic organs
- Evaluate the effectiveness of tumor therapy, as evidenced by a reduction in mass size
- Evaluate suspected fibroid tumor or bladder tumor
- Evaluate the thickness of the uterine wall
- Monitor placement and location of an IUD
- Monitor follicular size associated with fertility studies or to remove follicles for in vitro transplantation

**RESULT:**

**Normal findings in:**
- Normal size, position, location, and structure of pelvic organs (e.g., uterus, ovaries, fallopian tubes, vagina); IUD properly positioned within the uterine cavity

**Abnormal findings in:**
- Endometrioma
- Fibroids (leiomyoma)
- Nonovarian cyst
- Ovarian cysts
- Pelvic abscess
- Peritonitis
- PID
- Uterine tumor or adnexal tumor

**CRITICAL VALUES:**
- Abcess
- Adnexal torsion
- Appendicitis
- Ectopic pregnancy

- Infection
- Tumor with significant mass effect

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

**INTERFERING FACTORS:**

*This procedure is contraindicated for:*
- Patients with latex allergy; use of the vaginal probe requires the probe to be covered with a condom-like sac, usually made from latex. Some covers that are latex-free are available.

*Factors that may impair clear imaging:*
- Incorrect placement of the transducer over the desired test site
- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Dehydration, which can cause failure to demonstrate the boundaries between organs and tissue structures
- Insufficiently full bladder, which fails to push the bowel from the pelvis and the uterus from the symphysis pubis, thereby prohibiting clear imaging of the pelvic organs in transabdominal imaging
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

**Other considerations:**
- Failure to follow dietary/fluid instructions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.
Ultrasonic examination of the pelvis, gynecologic, nonobstetric

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses pelvic organ function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of results of the patient’s genitourinary, reproductive, and GI systems and symptoms, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
- Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography (CT) of the abdomen, if ordered, should be scheduled after this procedure.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- Instruct the patient that a latex or sterile sheath-covered probe will be inserted into the vagina for the transvaginal approach.

INTRA-TEST:
- Ensure that food and fluids have been restricted for at least 8 hr prior to the procedure.
- Ensure the patient receiving transabdominal US drank three to five glasses of fluid 90 min before the exam.
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to change into the gown, robe, and foot coverings provided. Remind her not to void before the procedure. Patients receiving transvaginal US do not need to have a full bladder.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table. The right- or left-side-up positions may be used to allow gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- Expose the abdominal and pelvic area and drape the patient.
- Transabdominal approach: Conductive gel is applied to the skin, and a transducer is moved over the skin while the bladder is distended to obtain images of the area of interest.
- Transvaginal approach: A covered and lubricated probe is inserted into the vagina and moved to different levels. Images are obtained and recorded.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold her breath.

POST-TEST:
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
Require the patient to void, as needed.
- When the study is completed, remove the gel from the skin.
- Instruct the patient to resume usual diet and fluids, as directed by the HCP.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include CEA and cancer antigens, colposcopy, CT abdomen, hysterosalpingography, laparoscopy gynecologic, KUB study, and MRI abdomen, PAP smear, and PET pelvis.
- Refer to the Genitourinary, Reproductive, and Gastrointestinal System tables at the back of the book for related tests by body system.

Ultrasound, Prostate (Transrectal)

SYNONYM/ACRONYM: Prostate sonography.

AREA OF APPLICATION: Prostate, seminal vesicles.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Prostate US is used for the evaluation of disorders of the prostate, especially in response to an elevated concentration of prostate-specific antigen on a blood test and as a complement to a digital rectal examination. It uses high-frequency waves of various intensities delivered by a transducer, a candle-shaped device, which is lubricated, sheathed with a condom, and inserted a few inches into the rectum. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to evaluate the structure, size, and position of the contents of the prostate (e.g., masses), as well as other prostate pathology. It aids in the diagnosis of prostatic cancer by evaluating palpable nodules and is useful as a guide to biopsy. This procedure can evaluate prostate tissue, the seminal vesicles, and surrounding perirectal tissue. It can also be used to stage carcinoma and to assist in radiation seed placement. The examination is helpful in monitoring patient response to therapy for prostatic disease. Micturition disorders can also be evaluated by this procedure. Prostate US
may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures.

**INDICATIONS:**
- Aid in the diagnosis of micturition disorders
- Aid in prostate cancer diagnosis
- Assess prostatic calcifications
- Assist in guided needle biopsy of a suspected tumor
- Assist in radiation seed placement
- Determine prostatic cancer staging
- Detect prostatitis

**RESULT:**

**Normal findings in:**
- Normal size, consistency, and contour of the prostate gland

**Abnormal findings in:**
- Benign prostatic hypertrophy or hyperplasia
- Micturition disorders
- Perirectal abscess
- Perirectal tumor
- Prostate abscess
- Prostate cancer
- Prostatitis
- Rectal tumor
- Seminal vesicle tumor

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

This procedure is contraindicated for:
- Patients with latex allergy; use of the rectal probe requires the probe to be covered with a condom, usually made from latex. Some covers that are latex-free are available.

Factors that may impair clear imaging:
- Attenuation of the sound waves by the pelvic bones, which can impair clear imaging of the prostate
- Incorrect placement of the transducer over the desired test site
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

Other considerations:
- Failure to follow pretesting preparations may cause the procedure to be canceled or repeated.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.
Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.

Inform the patient that a sterile latex- or sheath-covered probe will be inserted into the rectum. Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRA-TEST:**

- Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient on the examining table on his left side with his knees bent toward the chest; other positions may be used during the examination.
- Expose the rectal area and drape the patient.
- Cover the rectal probe with a lubricated condom and insert it into the rectum. Inform the patient that he may feel slight pressure as the transducer is inserted. Water may be introduced through the sheath surrounding the transducer.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his breath.

**POST-TEST:**

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- When the study is completed, remove the gel from the skin.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include biopsy prostate, CT pelvis, cystoscopy, cystourethrography voiding, IVP, KUB study, MRI pelvis, proctosigmoidoscopy, PSA, renogram, retrograde ureteropyelography, and semen analysis.
- Refer to the Genitourinary System table at the back of the book for related tests by body system.
Ultrasound, Scrotal

**SYNONYM/ACRONYM:** Scrotal sonography, ultrasound of the testes, testicular ultrasound.

**AREA OF APPLICATION:** Scrotum.

**CONTRAST:** Done without contrast.

**DESCRIPTION:** Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Scrotal US is used for the evaluation of disorders of the scrotum. It is valuable in determining the internal components of masses (solid versus cystic) and for the evaluation of the testicle, extratesticular and intrascrotal tissues, benign and malignant tumors, and other scrotal pathology. It uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, which is pressed against the skin. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to evaluate the structure, size, and position of the contents of the scrotum. Scrotal US can be performed before or after a radionuclide scan for further clarification of a testicular mass. Extratesticular lesions such as hydrocele, hematocoele (blood in the scrotum), and pyocele (pus in the scrotum) can be identified, as can cryptorchidism (undescended testicles). Scrotal US may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures.

**INDICATIONS:**
- Aid in the diagnosis of a chronic inflammatory condition such as epididymitis
- Aid in the diagnosis of a mass and differentiate between a cyst and a solid tumor, as evidenced by specific waveform patterns or the absence of sound waves, respectively
- Aid in the diagnosis of scrotal or testicular size, abnormality, or pathology
- Aid in the diagnosis of testicular torsion and associated testicular infarction
- Assist guided needle biopsy of a suspected testicle tumor
- Determine the cause of chronic scrotal swelling or pain
- Determine the presence of a hydrocele, pyocele, spermatocele, or hernia before surgery
- Evaluate the effectiveness of treatment for testicular infections
- Locate an undescended testicle

**RESULT:**

*Normal findings in:*
- Normal size, position, and shape of the scrotum and structure of the testes
Abnormal findings in:
- Abscess
- Epididymal cyst
- Epididymitis
- Hematoma
- Hydrocele
- Infarction
- Microlithiasis
- Orchitis
- Pyocele
- Scrotal hernia
- Spermatocele
- Torsion
- Tumor, benign or malignant
- Tunica albuginea cyst
- Undescended testicle (cryptorchidism)
- Varicocele

CRITICAL VALUES:
- Testicular torsion
Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

INTERFERING FACTORS:
Factors that may impair clear imaging:
- Incorrect placement of the transducer over the desired test site
- Retained barium from a previous radiological procedure
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the scrotum.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s genitourinary and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
- Colonoscopy and computed tomography (CT) of the abdomen, if ordered, should be scheduled after this procedure.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department, by a health care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other
Ultrasound, Spleen

SYNONYM/ACRONYM: Spleen ultrasonography.

AREA OF APPLICATION: Spleen/left upper quadrant.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, non-invasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Spleen US uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to evaluate the structure, size, and position of the spleen. This test is valuable for determining the internal components of splenic masses (solid versus cystic) and evaluating other splenic pathology, splenic trauma, and left upper quadrant perisplenic tissues. It can be performed to supplement a radionuclide scan or computed tomography (CT). It is especially valuable in patients

positional may be used during the examination.
Expose the abdomen/pelvic area and drape the patient.
Lift the penis upward and gently tape it to the lower part of the abdomen. Elevate the scrotum with a rolled towel or sponge for immobilization. Display particular sensitivity toward the patient regarding any embarrassment he may feel during this part of the procedure.
Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest.
Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his breath.

POST-TEST:
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
When the study is completed, remove the gel from the skin.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
Related tests include AFP, CT pelvis, KUB study, MRI pelvis, and semen analysis.
Refer to the Genitourinary and Reproductive System tables at the back of the book for related tests by body system.

Access additional resources at davisplus.fadavis.com
who are in renal failure, are hypersensitive to contrast medium, or are pregnant, because it does not rely on adequate renal function or the injection of contrast medium to obtain a diagnosis. The procedure may also be used as a guide for biopsy, other interventional procedures, and abscess drainage. Spleen US may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures.

**INDICATIONS:**
- Detect the presence of a subphrenic abscess after splenectomy
- Detect splenic masses; differentiate between cysts or solid tumors (in combination with CT), as evidenced by specific waveform patterns or absence of sound waves, respectively; and determine whether they are intrasplenic or extrasplenic
- Determine late-stage sickle cell disease, as evidenced by decreased spleen size and presence of echoes
- Determine the presence of splenomegaly, and assess the size and volume of the spleen in these cases, as evidenced by increased echoes and visibility of the spleen
- Differentiate spleen trauma from blood or fluid accumulation between the splenic capsule and parenchyma
- Evaluate the effect of medical or surgical therapy on the progression or resolution of splenic disease
- Evaluate the extent of abdominal trauma and spleen involvement, including enlargement or rupture, after a recent trauma
- Evaluate the spleen before splenectomy performed for thrombocytopenic purpura

**RESULT:**

**Normal findings in:**
- Normal size, position, and contour of the spleen and associated structures

**Abnormal findings in:**
- Abscesses
- Accessory or ectopic spleen
- Infection
- Lymphatic disease; lymph node enlargement
- Splenic calcifications
- Splenic masses, tumors, cysts, or infarction
- Splenic trauma
- Splenomegaly

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

**Factors that may impair clear imaging:**
- Attenuation of the sound waves by the ribs and an aerated left lung, which can impair clear imaging of the spleen
- Masses near the testing site, which can displace the spleen and cause inaccurate results if confused with splenomegaly
- Dehydration, which can cause failure to demonstrate the boundaries between organs and tissue structures
- Incorrect placement of the transducer over the desired test site
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and can produce unclear images

**Other considerations:**
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses splenic function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic, immune, and gastrointestinal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
- Endoscopic retrograde cholangiopancreatography, colonoscopy, and CT of the abdomen, if ordered, should be scheduled after this procedure.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to remove jewelry and other metallic objects in the area to be examined.
- The patient should fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility.

**INTRATEST:**
- Ensure that food and fluids have been restricted for at least 8 hr prior to the procedure.
- Ensure that the patient has removed all external metallic objects in the area prior to the procedure.
- Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table. The right- or left-side-up position may be used to allow gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- Expose the abdominal area and drape the patient.
- Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- When the study is completed, remove the gel from the skin.
- Instruct the patient to resume usual diet and fluids, as directed by the HCP.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
- Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in
Ultrasound, Thyroid and Parathyroid

SYNONYM/ACRONYM: Thyroid sonography, parathyroid sonography, thyroid echo.

AREA OF APPLICATION: Thyroid, parathyroid, and anterior neck region.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Thyroid and parathyroid US uses high-frequency waves of various intensities delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back, converted to electrical energy, amplified by the transducer, and displayed on a monitor to determine the position, size, shape, weight, and presence of masses of the thyroid gland; enlargement of the parathyroid glands; and other abnormalities of the thyroid and parathyroid glands and surrounding tissues. The primary purpose of this procedure is to determine whether a nodule is a fluid-filled cyst (usually benign) or a solid tumor (possibly malignant). This procedure is useful in evaluating the glands’ response to medical treatment or assessing the remaining tissue after surgical resection.

The procedure may be indicated as a guide for biopsy, aspiration, or other interventional procedures. Thyroid and parathyroid US may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without any further imaging procedures; it is clearly the procedure of choice when examining the glands of pregnant patients. This procedure is usually done in combination with nuclear medicine imaging procedures and computed tomography (CT) of the neck. Despite the advantages of the procedure, in some cases it may not detect small nodules and lesions (less than 1 cm), leading to false-negative findings.

INDICATIONS:
• Assist in determining the presence of a tumor, as evidenced by an irregular border and shadowing at the distal edge, peripheral echoes, or high- and low-amplitude echoes, depending on the density

therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
• Related tests include angiography abdomen, biopsy bone marrow, complete blood count, platelet count, complete blood count, WBC count and differential, CT abdomen, KUB study, liver and spleen scan, MRI abdomen, sickle cell screen, and WBC scan.
• Refer to the Hematopoietic, Immune, and Gastrointestinal System tables at the back of the book for related tests by body system.
of the tumor mass; and diagnosing tumor type (e.g., benign, adenoma, carcinoma)
• Assist in diagnosing the presence of a cyst, as evidenced by a smoothly outlined, echo-free amplitude except at the far borders of the mass
• Assist in diagnosis in the presence of a parathyroid enlargement indicating a tumor or hyperplasia, as evidenced by an echo pattern of lower amplitude than that for a thyroid tumor
• Determine the need for surgical biopsy of a tumor or fine-needle biopsy of a cyst
• Differentiate among a nodule, solid tumor, or fluid-filled cyst
• Evaluate the effect of a therapeutic regimen for a thyroid mass or Graves' disease by determining the size and weight of the gland
• Evaluate thyroid abnormalities during pregnancy

RESULT:
Normal findings in:
• Normal size, position, contour, and structure of the thyroid and parathyroid glands with uniform echo patterns throughout the glands; no evidence of tumor cysts or nodules in the glands

Abnormal findings in:
• Glandular enlargement
• Goiter
• Graves' disease
• Parathyroid tumor or hyperplasia
• Thyroid cysts
• Thyroid tumors (benign or malignant)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
Factors that may impair clear imaging:
• Attenuation of the sound waves by the ribs, which can impair clear imaging of the parathyroid

Other considerations:
• Nodules less than 1 cm in diameter may not be detected.
• Nonthyroid cysts may appear the same as thyroid cysts.
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses thyroid and parathyroid function.
• Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
• Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health care provider (HCP), with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTEGRATED:**
- Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient in the supine position on an exam table; other positions may be used during the examination.
- Expose the neck and chest area and drape the patient.
- Hyperextend the neck, and place a pillow under the patient’s shoulders to maintain a comfortable position. (An alternative method of imaging includes the use of a bag filled with water or gel placed over the neck area.)
- Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest.
- Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- When the study is completed, remove the gel from the skin.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include antibodies antithyroglobulin, biopsy thyroid, chest x-ray, CT thorax, MRI chest, PTH, parathyroid scan, radioactive iodine uptake, thyroid-binding inhibitory immunoglobulin, thyroglobulin, thyroid scan, TSH, thyroxine free, thyroxine total, triiodothyronine free, and triiodothyronine total.
- Refer to the Endocrine System table in the back of the book for related tests by body system.

**Ultrasound, Venous Doppler, Extremity Studies**

**SYNONYM/ACRONYM:** Venous ultrasound, venous sonogram, venous duplex.

**AREA OF APPLICATION:** Veins of the upper and lower extremities.

**CONTRAST:** Done without contrast.
DESCRIPTION: Ultrasound (US) procedures are diagnostic, non-invasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. Peripheral venous Doppler US records sound waves to obtain information about the patency of the venous vasculature in the upper and lower extremities to identify narrowing or occlusions of the veins or arteries. In venous Doppler studies, the Doppler identifies moving red blood cells (RBCs) within the vein. The US beam is directed at the vein and through the Doppler transducer while the RBCs reflect the beam back to the transducer. The reflected sound waves or echoes are transformed by a computer into scans, graphs, or audible sounds. Blood flow direction, velocity, and the presence of flow disturbances can be readily assessed. The velocity of the blood flow is transformed as a “swishing” noise, audible through the audio speaker. If the vein is occluded, no swishing sound is heard.

For diagnostic studies, the procedure is done bilaterally. The sound emitted by the equipment corresponds to the velocity of the blood flow through the vessel occurring with spontaneous respirations. Changes in these sounds during respirations indicate the possibility of abnormal venous flow secondary to occlusive disease; the absence of sound indicates complete obstruction. Compression with a transducer augments a vessel for evaluation of thrombosis. Noncompressibility of the vessel indicates a thrombosis. Plethysmography may be performed to determine the filling time of calf veins to diagnose thrombotic disorder of a major vein and to identify incompetent valves in the venous system. An additional method used to evaluate incompetent valves is the Valsalva technique combined with venous duplex imaging.

INDICATIONS:
- Aid in the diagnosis of venous occlusion secondary to thrombosis or thrombophlebitis
- Aid in the diagnosis of superficial thrombosis or deep vein thrombosis (DVT) leading to venous occlusion or obstruction, as evidenced by absence of venous flow, especially upon augmentation of the extremity; variations in flow during respirations; or failure of the veins to compress completely when the extremity is compressed
- Detect chronic venous insufficiency, as evidenced by reverse blood flow indicating incompetent valves
- Determine if further diagnostic procedures are needed to make or confirm a diagnosis
- Determine the source of emboli when pulmonary embolism is suspected or diagnosed
- Determine venous damage after trauma to the site
- Differentiate between primary and secondary varicose veins
- Evaluate the patency of the venous system in patients with a swollen, painful leg
- Monitor the effectiveness of therapeutic interventions

RESULT:

Normal findings in:
- Normal Doppler venous signal that occurs spontaneously with the patient’s respiration
- Normal blood flow through the veins of the extremities with no evidence of vessel occlusion

Abnormal findings in:
- Chronic venous insufficiency
- Primary varicose veins

Access additional resources at davisplus.fadavis.com
Recannulization in the area of an old thrombus
Secondary varicose veins
Superficial thrombosis or DVT
Venous narrowing or occlusion secondary to thrombosis or thrombophlebitis
Venous trauma

CRITICAL VALUES:
• DVT

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

INTERFERING FACTORS:
This procedure is contraindicated for:
• Patients with an open or draining lesion

Factors that may impair clear imaging:
• Attenuation of the sound waves by bony structures, which can impair clear imaging of the vessels
• Cigarette smoking, because nicotine can cause constriction of the peripheral vessels
• Incorrect placement of the transducer over the desired test site
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
• Cold extremities, resulting in vasocostriction that can cause inaccurate measurements
• Occlusion proximal to the site being studied, which would affect blood flow to the area
• An abnormally large or swollen leg, making sonic penetration difficult
• Incorrect positioning of the patient, which may produce poor visualization of the area to be examined

Other considerations:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses the veins.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Report the presence of a lesion that is open or draining; maintain clean, dry dressing for the ulcer; protect the limb from trauma.
• Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium- or iodine-based contrast medium and this test.
• Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography of the abdomen, if ordered, should be scheduled after this procedure.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.
• Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
• There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
• Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
Instruct the patient to void and change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.

Observe standard precautions, and follow the general guidelines in Appendix A.

Place the patient in the supine position on an exam table; other positions may be used during the examination.

Expose the area of interest and drape the patient.

Conductive gel is applied to the skin, and a transducer is moved over the area to obtain images of the area of interest. Waveforms are visualized and recorded with variations in respirations. Images with and without compression are performed proximally or distally to an obstruction to obtain information about a venous occlusion or obstruction. The procedure can be performed for both arms and legs to obtain bilateral blood flow determination.

Do not place the transducer on an ulcer site when there is evidence of venous stasis or ulcer.

Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.

POST-TEST:

A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

When the study is completed, remove the gel from the skin.

Instruct the patient to continue diet, fluids, and medications, as directed by the HCP.

Nutritional considerations: A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.

Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include alveolar/arterial ratio, angiography pulmonary, blood gases, complete blood count, platelet count, CT angiography, d-dimer, FDP, fibrinogen, lung perfusion scan, lung ventilation scan, MRI abdomen, MRI angiography, aPTT, plethysmography, PT/INR, US arterial doppler lower extremity studies, and venography lower extremities.

Refer to the Cardiovascular System table in the back of the book for related tests by body system.
DESCRIPTION: The upper gastrointestinal (GI) series is a radiological examination of the esophagus, stomach, and small intestine after ingestion of barium sulfate, which is a milkshake-like, radiopaque substance. A combination of x-ray and fluoroscopy techniques is used to record the study. Air may be instilled to provide double contrast and better visualization of the lumen of the esophagus, stomach, and duodenum. If perforation or obstruction is suspected, a water-soluble iodinated contrast medium is used. This test is especially useful in the evaluation of patients experiencing dysphagia, regurgitation, gastroesophageal reflux (GER), epigastric pain, hematemeses, melena, and unexplained weight loss. This test is also used to evaluate the results of gastric surgery, especially when an anastomotic leak is suspected. When a small bowel series is included, the test detects disorders of the jejunum and ileum. The patient’s position is changed during the examination to allow visualization of the various structures and their function. The images are visualized on a fluoroscopic screen, recorded, and stored electronically or on x-ray film for review by a physician. Drugs such as glucagon may be given during an upper GI series to relax the GI tract; drugs such as metoclopramide (Reglan) may be given to accelerate the passage of the barium through the stomach and small intestine.

When the small bowel series is performed separately, the patient may be asked to drink several glasses of barium, or enteroclysis may be used to instill the barium. With enteroclysis, a catheter is passed through the nose or mouth and advanced past the pylorus and into the duodenum. Barium, followed by methylcellulose solution, is instilled via the catheter directly into the small bowel.

INDICATIONS:
- Determine the cause of regurgitation or epigastric pain
- Determine the presence of neoplasms, ulcers, diverticula, obstruction, foreign body, and hiatal hernia
- Evaluate suspected GER, inflammatory process, congenital anomaly, motility disorder, or structural change
- Evaluate unexplained weight loss or anemia
- Identify and locate the origin of hematemesis

RESULT:
Normal findings in:
- Normal size, shape, position, and functioning of the esophagus, stomach, and small bowel

Abnormal findings in:
- Achalasia
- Cancer of the esophagus
- Chalasis
- Congenital abnormalities
- Duodenal cancer, diverticula, and ulcers
- Esophageal diverticula, motility disorders, ulcers, varices, and inflammation
- Gastric cancer, tumors, and ulcers
- Gastritis
- Hiatal hernia
- Perforation of the esophagus, stomach, or small bowel
- Polyps
- Small bowel tumors
- Strictures
CRITICAL VALUES:
• Foreign body
• Perforated bowel
• Tumor with significant mass effect

Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

INTERFERING FACTORS:
This procedure is contraindicated for:
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
• Patients with an intestinal obstruction
• Patients suspected of having upper GI perforation, in whom barium should not be used

Factors that may impair clear imaging:
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

Other considerations:
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
• Patients with swallowing problems may aspirate the barium, which could interfere with the procedure and cause patient complications.
• Possible constipation or partial bowel obstruction caused by retained barium in the small bowel or colon may affect test results.
• This procedure should be done after a kidney x-ray (IV pyelography) or computed tomography (CT) of the abdomen or pelvis.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a lead apron or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses the upper GI system and/or small bowel.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
• Obtain a history of the patient’s GI system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Ensure that this procedure is performed before a barium swallow.
• Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
• Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
• Review the procedure with the patient. Address concerns about pain and explain to the patient that there may be moments of discomfort and some pain experienced during the procedure. Inform the patient that the procedure is usually performed in a radiology department by a HCP with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important
in providing psychological support before, during, and after the procedure. Explain to the patient that he or she will be asked to drink a milkshake-like solution that has an unpleasant chalky taste. Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure. Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility.

**INTRATEST:**
- Ensure that the patient has complied with dietary and fluid restrictions for 8 hr prior to the procedure.
- Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- Observe standard precautions, and follow the general guidelines in Appendix A.

**Upper Gastrointestinal Series:**
- Place the patient on the x-ray table in a supine position, or ask the patient to stand in front of an fluoroscopy screen.
- Instruct the patient to take several swallows of the barium mixture through a straw while images are taken of the pharyngeal motion. An effervescent agent may also be administered to introduce air into the stomach.

**Small Bowel Series:**
- If the small bowel is to be examined after the upper GI series, instruct the patient to drink an additional glass of barium while the small intestine is observed for passage of barium. Images are taken at 30- to 60-min intervals until the barium reaches the ileocecal valve. This process can last up to 5 hr, with follow-up images taken at 24 hr.

**POST-TEST:**
- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

**RELATED MONOGRAPHS:**
- Related tests include barium enema, barium swallow, capsule endoscopy, CT abdomen, endoscopic retrograde cholangiopancreatography, esophageal manometry, fecal analysis, gastric acid stimulation test, gastric emptying scan, gastrin stimulation test, gastroesophageal reflux scan, H. pylori, KUB study, MRI abdomen, and US pelvis.
- Refer to the Gastrointestinal System table at the back of the book for related tests by body system.
**Urea Breath Test**

**SYNONYM/ACRONYM:** PY test, C-14 Urea Breath Test, Breath Test, Pylori Breath Test, UBT.

**AREA OF APPLICATION:** Stomach.

**CONTRAST:** Radioactive C-14 urea in capsule form.

**DESCRIPTION:** The C-14 urea breath test (UBT) is used to assist in the diagnosis of *Helicobacter pylori* (*H. pylori*) infection. *H. pylori* is a bacteria that can infect the stomach lining. *H. pylori* has been implicated as the cause of many gastrointestinal conditions, including the development of duodenal and gastric ulcers. The UBT is a simple, noninvasive diagnostic nuclear medicine procedure that requires the patient to swallow a small amount of radiopharmaceutical C-14-labeled urea in a capsule with lukewarm water. In the presence of urease, an enzyme secreted by *H. pylori* in the gut, the urea in the capsule is broken down into nitrogen and C-14-labeled carbon dioxide (CO₂). The labeled CO₂ is absorbed through the stomach lining into the blood and excreted by the lungs. Breath samples are collected and trapped in a mylar balloon. The C-14 urea is counted and quantitated with a liquid scintillation counter. The UBT can also be used to indicate the elimination of *H. pylori* infection after treatment with antibiotics. Other tests used to detect the presence of *H. pylori* include a blood *H. pylori* antibody test, a stool antigen test, and stomach biopsy.

**INDICATIONS:**
- Aid in detection of the presence of *H. pylori* infection in the stomach
- Monitor eradication of *H. pylori* infection following treatment regimen
- Evaluation of new-onset dyspepsia

**RESULT:**

**Normal findings in:**
- Negative for *H. pylori*: Less than 50 dpm (disintegrations per minute)

**Abnormal findings in:**
- Indeterminate for *H. pylori*: 50–199 dpm
- Positive for *H. pylori*: Greater than 200 dpm

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

**This procedure is contraindicated for:**
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure outweigh the risks to the fetus and the mother
- Patients who have taken antibiotics, Pepto-Bismol, or bismuth in the past 30 days
- Patients who have used a proton pump inhibitor within the past 14 days
- Patients who have taken sucralfate in the past 14 days

Access additional resources at davisplus.fadavis.com
Other considerations:
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Patients who have had resective gastric surgery have the potential for resultant bacterial overgrowth (non-*H. pylori* urease), which can cause a false-positive result.
- Achlorhydria can cause a false-positive result.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses gastrointestinal (GI) infection.
- Obtain a history of the patient’s GI system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the last menstrual period and determine the possibility of pregnancy in premenopausal women.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Address concerns about pain and explain that there should be no discomfort during the procedure. Inform the patient that the procedure is done in the nuclear medicine department by technologists and support staff and usually takes approximately 30 to 60 min.
- Sensitivity to social and cultural issues is important in providing psychological support before, during, and after the procedure.

**INTRATEST:**
- Instruct the patient to fast, restrict fluids, and, by medical direction, withhold medication for 6 hr prior to the procedure. Protocols may vary from facility to facility.
- Ensure the patient has complied with dietary and medication restrictions and pretesting preparations; assure that food, fluids and medications have been restricted for at least 6 hr prior to the procedure.
- Instruct the patient to blow into a balloon prior to the start of the procedure to collect a sample of breath.
- Instruct the patient to swallow the C-14 capsule directly from a cup followed by 20 mL of lukewarm water. Provide an additional 20 mL of lukewarm water for the patient to drink at 3 min after the dose.
- Breath samples are taken at different periods of time by instructing the patient to take in a deep breath and hold it for approximately 5–10 sec before exhaling through a straw into a mylar balloon.
- Samples are counted on a liquid scintillation counter (LSC) and recorded in dpm.

**POST-TEST:**
- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual diet and medication, as directed by the HCP.
- Unless contraindicated, advise patient to drink increased amounts of fluids for 12 to 24 hr to eliminate the radionuclide from the body.
- If a woman who is breastfeeding must have a breathe test, she should not breastfeed the infant until the radionuclide has been eliminated. She should be instructed to express the milk and discard it during a 3-day period to prevent cessation of milk production.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further
testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of the procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include EGD, gastric emptying scan, *H. pylori* antibody, KUB study, and UGI.
- See the Gastrointestinal System table at the end of the book for related tests by body system.

---

**Urea Nitrogen, Blood**

**SYNONYM/ACRONYM:** BUN.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

**REFERENCE VALUE:** (Method: Spectrophotometry)

**DESCRIPTION:** Urea is a nonprotein nitrogen compound formed in the liver from ammonia as an end product of protein metabolism. Urea diffuses freely into extracellular and intracellular fluid and is ultimately excreted by the kidneys. Blood urea nitrogen (BUN) levels reflect the balance between the production and excretion of urea. BUN and creatinine values are commonly evaluated together. The normal BUN/creatinine ratio is 15:1 to 24:1. (e.g., if a patient has a BUN of 15 mg/dL, the creatinine should be approximately 0.6 to 1.0 mg/dL). BUN is used in the following calculation to estimate serum osmolality:

\[
(2 \times Na^+) + \frac{(\text{glucose}/18)}{(\text{BUN}/2.8)}
\]

**INDICATIONS:**
- Assess nutritional support
- Evaluate hemodialysis therapy
- Evaluate hydration
- Evaluate liver function
- Evaluate patients with lymphoma after chemotherapy (tumor lysis)
- Evaluate renal function
- Monitor the effects of drugs known to be nephrotoxic or hepatotoxic

Access additional resources at davisplus.fadavis.com
RESULT:

Increased in:
• Acute renal failure (Related to decreased renal excretion)
• Chronic glomerulonephritis (Related to decreased renal excretion)
• Congestive heart failure (Related to decreased blood flow to the kidneys, decreased renal excretion, and accumulation in circulating blood)
• Decreased renal perfusion (Reflects decreased renal excretion and increased blood levels)
• Diabetes (Related to decreased renal excretion)
• Excessive protein ingestion (Related to increased protein metabolism)
• Gastrointestinal (GI) bleeding (Excessive blood protein in the GI tract and increased protein metabolism)
• Hyperalimentation (Related to increased protein metabolism)
• Hypovolemia (Related to decreased blood flow to the kidneys, decreased renal excretion, and accumulation in circulating blood)
• Ketoacidosis (Dehydration from ketoacidosis correlates with decreased renal excretion of urea nitrogen)
• Muscle wasting from starvation (Related to increased protein metabolism)
• Neoplasms (Related to increased protein metabolism or to decreased renal excretion)
• Nephrotoxic agents (Related to decreased renal excretion and accumulation in circulating blood)
• Urinary tract obstruction (Related to decreased renal excretion and accumulation in circulating blood)

Decreased in:
• Inadequate dietary protein (Urea nitrogen is a by-product of protein metabolism; less available protein is reflected in decreased BUN levels)
• Low-protein/high-carbohydrate diet (Urea nitrogen is a by-product of protein metabolism; less available protein is reflected in decreased BUN levels)
• Malabsorption syndromes (Urea nitrogen is a by-product of protein metabolism; less available protein is reflected in decreased BUN levels)
• Pregnancy
• Severe liver disease (BUN is synthesized in the liver so liver damage results in decreased levels)

CRITICAL VALUES:

Greater than 100 mg/dL (non-dialysis patients)

Note and immediately report to the health care provider (HCP) any critically increased or decreased values and related symptoms. A patient with a grossly elevated BUN may have signs and symptoms including acidemia, agitation, confusion, fatigue, nausea, vomiting, and coma. Possible interventions include treatment of the cause, administration of IV bicarbonate, a low-protein diet, hemodialysis, and caution with respect to prescribing and continuing nephrotoxic medications.

INTERFERING FACTORS:
• Drugs, substances, and vitamins that may increase BUN levels include acetaminophen, alanine, aldatense, alkaline antacids, amphotericin B, antimony compounds, arsenicals, bacitracin, bismuth subsalicylate, capreomycin, carbenoxolone, carbutamide,
UREA NITROGEN, BLOOD

cephalosporins, chloral hydrate, chloramphenicol, clorthalidone, colistimethate, colistin, cotrimoxazole, dexamethasone, dextran, diclofenac, doxycycline, ethylene glycol, gentamicin, guanethidine, guanoxan, ibuprofen, ifosfamide, ipodate, kanamycin, mephenesin, metolazone, mitomycin, neomycin, phosphorus, plicamycin, tertatolol, tetracycline, triamterene, triethyleneemelamine, viomycin, and vitamin D.

- Drugs that may decrease BUN levels include acetohydroxamic acid, chloramphenicol, fluorides, paramethasone, phenothiazine, and streptomycin.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess renal function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.

**POST-TEST:**
- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Monitor intake and output for fluid imbalance in renal dysfunction and dehydration.
- **Nutritional considerations:** Nitrogen balance is commonly used as a nutritional assessment tool to indicate protein change. In healthy individuals, protein anabolism and catabolism are in equilibrium. During various disease states, nutritional intake decreases, resulting in a negative balance. During recovery from illness and with proper nutritional support, the nitrogen balance becomes positive. BUN is an important analyte to measure during administration of total parenteral nutrition (TPN). Educate the patient, as appropriate, in dietary adjustments required to maintain proper nitrogen balance. Inform the patient that the requesting HCP may prescribe TPN as part of the treatment plan.
- **Nutritional considerations:** An elevated BUN can be caused by a high-protein diet or dehydration. Unless medically restricted, a healthy diet consisting of the five food groups of the food pyramid should be consumed daily. Water consumption should include six to eight 8-oz glasses of water per day, or water consumption equivalent to half of the body’s weight in fluid ounces (32 fl oz = 1 qt; 34 fl oz = 1 L).
- Recognize anxiety related to test results. Discuss the implications of
abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include anion gap, antibiotic drugs, biopsy kidney, calcium, calculus kidney stone panel, CT spleen, creatinine, creatinine clearance, cytology urine, cystoscopy, electrolytes, gallium scan, glucose, glycated hemoglobin, 5–HIAA, IVP, ketones, magnesium, microalbumin, osmolality, oxalate, phosphorus, protein total and fractions, renogram, US kidney, UA, urea nitrogen urine, and uric acid.
- Refer to the Genitourinary System table at the back of the book for related tests by body system.

---

**Urea Nitrogen, Urine**

**SYNONYM/ACRONYM:** N/A.

**SPECIMEN:** Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

**REFERENCE VALUE:** (Method: Spectrophotometry)

**DESCRIPTION:** Urea is a nonprotein nitrogen compound formed in the liver from ammonia as an end product of protein metabolism. Urea diffuses freely into extracellular and intracellular fluid and is ultimately excreted by the kidneys. Urine urea nitrogen levels reflect the balance between the production and excretion of urea.

**INDICATIONS:**
- Evaluate renal disease
- Predict the impact that other conditions, such as diabetes and liver disease, will have on the kidneys

**RESULT:**

**Increased in:**
- Diabetes *(Related to decreased renal excretion)*
- Hyperthyroidism
- Increased dietary protein *(Related to increased protein metabolism)*
- Postoperative period

**Decreased in:**
- Liver disease *(BUN is synthesized in the liver so liver damage results in decreased levels)*
• Low-protein/high-carbohydrate diet  
  (*Urea nitrogen is a by-product of protein metabolism; less available protein is reflected in decreased BUN levels*)
• Normal-growing pediatric patients  
  (*Increased demand for protein; less available protein is reflected in decreased BUN levels*)
• Pregnancy  
  (*Increased demand for protein; less available protein is reflected in decreased BUN levels*)
• Renal disease  
  (*Related to decreased renal excretion*)
• Toxemia  
  (*Related to hypertension and decreased renal excretion*)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
• Drugs that may increase urine urea nitrogen levels include alanine and glycine.
• Drugs that may decrease urine urea nitrogen levels include furosemide, growth hormone, insulin, and testosterone.
• All urine voided for the timed collection period must be included in the collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess renal function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s genitourinary and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

**INTEST:**

- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.

**Random Specimen (collect in early morning):**

- Clean-catch specimen:
  - Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.

Access additional resources at davisplus.fadavis.com
Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

**Indwelling Catheter:**

Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

**Timed Specimen:**

Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.

Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.

If an indwelling catheter is in place, replace the tubing and container system at the start of the collection period. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.

At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.

Include on the collection container’s label the amount of urine, test start and stop times, and ingestion of any medications that can affect test results.

**General:**

Promptly transport the specimen to the laboratory for processing and analysis.

**Post-test:**

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

**Nutritional considerations:**

An elevated BUN can be caused by a high-protein diet or dehydration. Unless medically restricted, a healthy diet consisting of the five food groups of the food pyramid should be consumed daily. Water consumption should include six to eight 8-ounce glasses of water per day, or water consumption equivalent to half of the body’s weight in fluid ounces (32 fl oz = 1 qt; 34 fl oz = 1 L).

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**Related Monographs:**

Related tests include anion gap, antibiotic drugs, biopsy kidney, BUN, calcium, calculus kidney stone panel, CT spleen, creatinine, creatinine clearance, cytology urine, cystoscopy, electrolytes, gallium scan, glucose, glycated hemoglobin, 5–HIAA, IVP, ketones, magnesium, microalbumin, osmolality, oxalate, phosphorus, protein total and fractions, renogram, US kidney, UA, blood urea nitrogen, and uric acid.

Refer to the Genitourinary and Hepatobiliary System tables at the back of the book for related tests by body system.
Urethrography, Retrograde

SYNONYM/ACRONYM: N/A.

AREA OF APPLICATION: Urethra.

CONTRAST: Radiopaque contrast medium.

DESCRIPTION: Retrograde urethrography is performed almost exclusively in male patients. It uses contrast medium, either injected or instilled via a catheter into the urethra, to visualize the membranous, bulbar, and penile portions, particularly after surgical repair of the urethra to assess the success of the surgery. The posterior portion of the urethra is visualized better when the procedure is performed with voiding cystourethrography. In women, it may be performed after surgical repair of the urethra to assess the success of the surgery and to assess structural abnormalities in conjunction with an evaluation for voiding dysfunction.

INDICATIONS:
- Aid in the diagnosis of urethral strictures, lacerations, diverticula, and congenital anomalies

RESULT:

Normal findings in:
- Normal size, shape, and course of the membranous, bulbar, and penile portions of the urethra in male patients
- If the prostatic portion can be visualized, it also should appear normal

Abnormal findings in:
- Congenital anomalies, such as urethral valves and perineal hypospadias

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients with allergies to shellfish or iodinated contrast medium. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.

Factors that may impair clear imaging:
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Access additional resources at davisplus.fadavis.com
Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

**Other considerations:**
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a lead apron or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the urethra.
- Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
- Obtain a history of the patient’s gastrointestinal (GI) and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Ensure that this procedure is performed before an upper GI study or barium swallow.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the procedure. Inform the patient that the procedure is performed in a cystoscopy room by a HCP, with support staff, and takes approximately 30 min.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Inform the patient that some pressure may be experienced when the catheter is inserted and contrast medium is instilled.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- There are no food or fluid restrictions, unless by medical direction.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

**INTRATEST:**
- Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to lie still during the procedure because movement produces unclear images.
- Obtain and record the patient's baseline vital signs.
- Observe standard precautions, and follow the general guidelines in Appendix A.
- Place the patient on the table in a supine position.
- A single plain film is taken of the bladder and urethra.
- A catheter is filled with contrast medium to eliminate air pockets and is inserted until the balloon reaches the meatus. Inform the patient that the contrast medium may cause a
temporary flushing of the face, a feeling of warmth, urticaria, headache, vomiting, or nausea.

After three-fourths of the contrast medium is injected, another image is taken while the remainder of the contrast medium is injected.

The procedure may be done on female patients using a double balloon to occlude the bladder neck from above and below the external meatus.

**POST-TEST:**

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual activities, as directed by the HCP.

Monitor vital and neurological signs every 15 min until they return to preprocedure levels.

Monitor fluid intake and urinary output for 24 hr after the procedure. Decreased urine output may indicate impending renal failure.

Monitor for signs and symptoms of sepsis, including fever, chills, and severe pain in the kidney area.

Instruct the patient to drink plenty of fluids to prevent stasis and to prevent the buildup of bacteria.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

Related tests include CT abdomen, CT pelvis, cystometry, cystoscopy, IVP, MRI abdomen, PSA, renogram, retrograde ureteropyelography, urinalysis, and voiding cystourethrography.

Refer to the Genitourinary System table in the back of the book for related tests by body system.

---

**Uric Acid, Blood**

**SYNONYM/ACRONYM:** Urate.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

**REFERENCE VALUE:** (Method: Spectrophotometry)

DESCRIPTION: Uric acid is the end product of purine metabolism. Purines are important constituents of nucleic acids; purine turnover occurs continuously in the body, producing substantial amounts of uric acid even in the absence of purine intake from dietary sources such as organ meats (e.g., liver, thymus gland and/or pancreas [sweetbreads], kidney), legumes, and yeasts. Uric acid is filtered, absorbed, and secreted by the kidneys and is a common constituent of urine. Serum urate levels are affected by the amount of uric acid produced and by the efficiency of renal excretion.

INDICATIONS:
- Assist in the diagnosis of gout when there is a family history (autosomal dominant genetic disorder) or signs and symptoms of gout, indicated by elevated uric acid levels
- Determine the cause of known or suspected renal calculi
- Evaluate the extent of tissue destruction in infection, starvation, excessive exercise, malignancies, chemotherapy, or radiation therapy
- Evaluate possible liver damage in eclampsia, indicated by elevated uric acid levels
- Monitor the effects of drugs known to alter uric acid levels, either as a side effect or as a therapeutic effect

RESULT:

**Increased in:**
- Alcoholism
- Chemotherapy and radiation therapy (Related to high cellular turnover)
- Chronic lead toxicity (Cellular destruction related to bemiolysis)
- Congestive heart failure (Cellular destruction)
- Diabetes (Decreased renal excretion results in increased blood levels)
- Down syndrome
- Eclampsia
- Excessive dietary purines (Purines are nucleic acid bases converted to uric acid by the liver)
- Glucose-6-phosphate dehydrogenase deficiency (Cellular destruction related to bemiolysis)
- Gout (Usually related to excess dietary intake)
- Hyperparathyroidism
- Hypertension (Related to effects on renal excretion)
- Hypoparathyroidism (Related to disturbances in calcium and phosphorus homeostasis)
- Lactic acidosis (Cellular destruction related to shock)
- Lead poisoning (Cellular destruction related to bemiolysis)
- Lesch-Nyhan syndrome (Disorder of uric acid metabolism)
- Multiple myeloma (High cell turnover)
- Pernicious anemia (Cellular destruction related to bemiolysis)
- Polycystic kidney disease (Decreased renal excretion results in increased blood levels)
- Polycythemia (Increased cellular destruction)
- Psoriasis
- Sickle cell anemia (Cellular destruction related to bemiolysis)
- Type III hyperlipidemia

**Decreased in:**
- Fanconi's syndrome (Renal excretion is increased)
- Low-purine diet (Insufficient nutrients for liver to synthesize uric acid)
• Severe liver disease (Uric acid synthesis occurs in the liver)
• Wilson’s disease (Affects normal liver function and is related to impaired tubular absorption)

CRITICAL VALUES: N/A

INTERFERING FACTORS:
• Drugs and substances that may increase uric acid levels include acetylsalicylic acid (low doses), aldatense, aminothiadiazole, anabolic steroids, antineoplastic agents, ascorbic acid, chlorambucil, chlorothalidone, cisplatin, corn oil, cyclosporine, cyclothiazide, cytarabine, diapamid, diazoxide, diuretics, ergothioneine, ethacrynic acid, ethambutol, ethoxzolamide, etoposide, flumethiazide, hydroflumethiazide, hydroxyurea, ibufenac, ibuprofen, levarterenol, levodopa, mefruside, mercaptopurine, mexitilin, methotrexate, methoxyflurane, methyclothiazide, mitomycin, morinamide, polythiazide, prednisone, pyrazinamide, salicylate, spironolactone, theophylline, thiazide diuretics, thio-guanine, thiotepa, thiouric acid, triamterene, trichlormethiazide, vincristine, warfarin, and xylitol.
• Drugs that may decrease uric acid levels include acetohexamide, allopurinol, aspirin (high doses), azathioprine, benz bromaron, benziiodarone, canola oil, chlorothiazide (given IV), chlorpromazine, chlorprothixene, cinchophen, corticosteroids, corticotropin, clofibrate, coumarin, diatrizoic acid, dicumarol, dipyrone, enalapril, fenofibrate, flufenamic acid, guaifenesin, hydralazine, iodipamide, iodopyracet, iopanoic acid, ipodate, lisinopril, mafenamic acid, mersalyl, methotrexate, oxyphenbutazone, phenindione, phenolsulfonphthalein, probenecid, seclazone, sulfapirazone, and verapamil.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
➧ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
➧ Inform the patient that the test is primarily used to diagnose gout and to evaluate renal function.
➧ Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex. Especially note pain and edema in joints and great toe (caused by precipitation of sodium urates), headache, fatigue, decreased urinary output, and hypertension.
➧ Obtain a history of the patient’s genitourinary, hepatobiliary, and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
➧ Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
➧ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
➧ There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
➧ If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
➧ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
➧ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
➧ Remove the needle and apply direct pressure with dry gauze to stop
bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage. Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

**Nutritional considerations:** Increased uric acid levels may be associated with the formation of kidney stones. Educate the patient, if appropriate, on the importance of drinking a sufficient amount of water when kidney stones are suspected.

**Nutritional considerations:** Increased uric acid levels may be associated with gout. Nutritional therapy may be appropriate for some patients identified as having gout. Educate the patient that foods high in oxalic acid include caffeinated beverages, raw blackberries, gooseberries and plums, whole-wheat bread, beets, carrots, beans, rhubarb, spinach, dry cocoa, and Ovaltine. Foods high in purines include organ meats, which should be restricted. In other cases, the requesting HCP may not prescribe a low-purine or purine-restricted diet for treatment of gout because medications can control the condition easily and effectively.

- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include arthroscopy, biopsy bone marrow, calcium, calculus kidney stone panel, cholesterol, collagen cross-linked telopeptide, complete blood count, complete blood count, RBC count, complete blood count, RBC indices, complete blood count, RBC morphology, creatinine, creatinine clearance, gastrin stimulation, G6PD, lactic acid, lead, PTH, parathyroid scan, phosphorus, sickle cell screen, synovial fluid analysis, UA, and urine uric acid.

- Refer to the Genitourinary, Hepatobiliary, and Musculoskeletal System tables at the back of the book for related tests by body system.

---

**Uric Acid, Urine**

**SYNONYM/ACRONYM:** Urine urate.

**SPECIMEN:** Urine (5 mL) from a random or timed specimen collected in a clean plastic, unrefrigerated collection container. Sodium hydroxide preservative may be recommended to prevent precipitation of urates.

**REFERENCE VALUE:** (Method: Spectrophotometry)
**DESCRIPTION:** Uric acid is the end product of purine metabolism. Purines are important constituents of nucleic acids; purine turnover occurs continuously in the body, producing substantial amounts of uric acid even in the absence of purine intake from dietary sources such as organ meats (e.g., liver, thymus gland and/or pancreas [sweetbreads], kidney), legumes, and yeasts. Uric acid is filtered, absorbed, and secreted by the kidneys and is a common constituent of urine.

**INDICATIONS:**
- Compare urine and serum uric acid levels to provide an index of renal function
- Detect enzyme deficiencies and metabolic disturbances that affect the body’s production of uric acid
- Monitor the response to therapy with uricosuric drugs
- Monitor urinary effects of disorders that cause hyperuricemia

**RESULT:**

**Increased in:**
- Disorders associated with impaired renal tubular absorption, such as Fanconi’s syndrome and Wilson’s disease
- Disorders of purine metabolism
- Excessive dietary intake of purines
- Gout
- Neoplastic disorders, such as leukemia, lymphosarcoma, and multiple myeloma (Related to increased cell turnover)

**Decreased in:**
- Folic acid deficiency
- Lead toxicity
- Severe renal damage (Possibly resulting from chronic glomerulonephritis, collagen disorders, diabetic glomerulosclerosis, lactic acidosis, ketoacidosis, or alcohol abuse)

**INTERFERING FACTORS:**
- Drugs that may increase urine uric acid levels include acetaminophen, acetohexamide, ampicillin, ascorbic acid, azapropazone, benzbro- maron, chlorpromazine, chlorprothixene, corticotropin, coumarin, cytotoxics, diatrizoic acid, dicumarol, ethyl biscomacetate, glycine, iodipamide, iodopyracet, iopanoic acid, ipodate, levodopa, mannose, merbarone, mercaptopurine, mersalyl, methotrexate, niacinamide, phenindione, phenolsulfonphthalein, phenylbutazone, phloridzin, probenecid, salicylates (long-term, large doses), seclazone, sulfipyrazone, theophylline, verapamil, and xylitol.
- Drugs that may decrease urine uric acid levels include acetylsalicylic acid (small doses), allopurinol, ascorbic acid, azathioprine, benzbromaron, bumetanide, chlorothiazide, chlorthalidone, citrates, ethacrynic acid, ethambutol, ethoxzolamide, hydrochlorothiazide, and probenecid.

**CRITICAL VALUES:** N/A

*Values reflect average purine diet.
levaterenol, niacin, pyrazinoic acid, and thiazide diuretics.

- All urine voided for the timed collection period must be included in the collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to identify overexcretors at risk of calculus formation, identify genetic defects, and assist in monitoring therapy for gout.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.
- Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen.

Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date, and time of collection.

**Random Specimen (collect in early morning):**

**Clean-catch specimen:**
- Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

**Indwelling Catheter:**
- Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.
Timed Specimen:
- Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
- If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- Include on the collection container’s label the amount of urine, test start and stop times, and any medications that can affect test results.

General:
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Increased uric acid levels may be associated with the formation of kidney stones. Educate the patient, if appropriate, on the importance of drinking a sufficient amount of water when kidney stones are suspected.

Nutritional considerations: Increased uric acid levels may be associated with gout. Nutritional therapy may be appropriate for some patients identified as having gout. Educate the patient that foods high in oxalic acid include caffeinated beverages, raw blackberries, gooseberries and plums, whole-wheat bread, beets, carrots, beans, rhubarb, spinach, dry cocoa, and Ovaltine. Foods high in purines include organ meats, which should be restricted. In other cases, the requesting HCP may not prescribe a low-purine or purine-restricted diet for treatment of gout because medications can control the condition easily and effectively.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include arthroscopy, biopsy bone marrow, calcium, calculus kidney stone panel, cholesterol, collagen cross-linked telopeptide, complete blood count, complete blood count, RBC count, complete blood count, RBC indices, complete blood count, RBC morphology, creatinine, creatinine clearance, gastrin stimulation, G6PD, lactic acid, lead, oxalate, PTH, parathyroid scan, phosphorus, sickle cell screen, synovial fluid analysis, UA, and blood uric acid.
- Refer to the Genitourinary System table at the back of the book for related tests by body system.
Urinalysis

SYNONYM/ACRONYM: UA.

SPECIMEN: Urine (15 mL) from an unpreserved, random specimen collected in a clean plastic collection container.

REFERENCE VALUE: (Method: Macroscopic evaluation by dipstick and microscopic examination) Urinalysis comprises a battery of tests including a description of the color and appearance of urine; measurement of specific gravity and pH; and semiquantitative measurement of protein, glucose, ketones, urobilinogen, bilirubin, hemoglobin, nitrites, and leukocyte esterase. Urine sediment may also be examined for the presence of crystals, casts, renal epithelial cells, transitional epithelial cells, squamous epithelial cells, white blood cells (WBCs), red blood cells (RBCs), bacteria, yeast, sperm, and any other substances excreted in the urine that may have clinical significance. Examination of urine sediment is performed microscopically under high power, and results are reported as the number seen per high-power field (hpf). The color of normal urine ranges from light yellow to deep amber. The color depends on the patient’s state of hydration (more concentrated samples are darker in color), diet, medication regimen, and exposure to other substances that may contribute to unusual color or odor. The appearance of normal urine is clear. Cloudiness is sometimes attributable to the presence of amorphous phosphates or urates as well as blood, WBCs, fat, or bacteria. Normal specific gravity is 1.001 to 1.029.

**DESCRIPTION:** Routine urinalysis, one of the most widely ordered laboratory procedures, is used for basic screening purposes. It is a group of tests that evaluate the kidneys’ ability to selectively excrete and reabsorb substances while maintaining proper water balance. The results can provide valuable information regarding the overall health of the patient and the patient’s response to disease and treatment. The urine dipstick has a number of pads on it to indicate various biochemical markers. Urine pH is an indication of the kidneys’ ability to help maintain balanced hydrogen ion concentration in the blood. Specific gravity is a reflection of the concentration ability of the kidneys. Urine protein is the most common indicator of renal disease, although there are conditions that can cause benign proteinuria. Glucose is used as an indicator of diabetes. The presence of ketones indicates impaired carbohydrate metabolism. Hemoglobin indicates the presence of blood, which is associated with renal disease. Bilirubin is used to assist in the detection of liver disorders. Urobilinogen indicates hepatic or hematopoietic conditions. Nitrites and leukocytes are used to test for bacteriuria and other sources of urinary tract infections (UTIs). Most laboratories have established criteria for the microscopic examination of urine based on patient population (e.g., pediatric, oncology, urology), unusual appearance, and biochemical reactions.

**INDICATIONS:**
- Determine the presence of a genitourinary infection or abnormality
- Monitor the effects of physical or emotional stress
- Monitor fluid imbalances or treatment for fluid imbalances
- Monitor the response to drug therapy and evaluate undesired reactions to drugs that may impair renal function
- Provide screening as part of a general physical examination, especially on admission to a health care facility or before surgery

**Formed Elements in Urine Sediment**

**Cellular Elements:**
- Clue cells (cell wall of the bacteria causes adhesion to epithelial cells) are present in nonspecific vaginitis caused by *Gardnerella vaginitis*, *Mobiluncus cortisii*, and *Mobiluncus mulieris*.
- RBCs are present in glomerulonephritis, lupus nephritis, focal glomerulonephritis, calculus, malignancy, infection, tuberculosis, infarction, renal vein thrombosis, trauma, hydronephrosis, polycystic kidney, urinary tract disease, prostatitis, pyelonephritis, appendicitis, salpingitis, diverticulitis, gout, scurvy, subacute bacterial endocarditis, infectious mononucleosis, hemoglobinopathies, coagulation disorders, heart failure, and malaria.
- Renal cells that have absorbed cholesterol and triglycerides are also known as *oval fat bodies*.
- Renal cells come from the lining of the collecting ducts, and increased numbers indicate acute tubular damage as seen in acute tubular necrosis, pyelonephritis, malignant nephrosclerosis, acute glomerulonephritis, acute drug or substance (salicylate, lead, or ethylene glycol) intoxication, or chemotherapy, resulting in desquamation, urolithiasis, and kidney transplant rejection.
- Squamous cells line the vagina and distal portion of the urethra. The presence of normal squamous epithelial cells in female urine is generally of no clinical significance. Abnormal cells with enlarged nuclei indicate the need for cytological studies to rule out malignancy.
- Transitional cells line the renal pelvis, ureter, bladder, and proximal portion of the urethra. Increased numbers are seen with infection, trauma, and malignancy.

Access additional resources at davisplus.fadavis.com
• WBCs are present in acute UTI, tubulointerstitial nephritis, lupus nephritis, pyelonephritis, kidney transplant rejection, fever, and strenuous exercise.

**Casts:**
- Granular casts are formed from protein or by the decomposition of cellular elements. They may be seen in renal disease, viral infections, or lead intoxication.
- Large numbers of hyaline casts may be seen in renal diseases, hypertension, congestive heart failure, or nephrotic syndrome, and in more benign conditions such as fever, exposure to cold temperatures, exercise, or diuretic use.
- RBC casts may be found in acute glomerulonephritis, lupus nephritis, and subacute bacterial endocarditis.
- Waxy casts are seen in chronic renal failure or conditions such as kidney transplant rejection, in which there is renal stasis.
- WBC casts may be seen in lupus nephritis, acute glomerulonephritis, interstitial nephritis, and acute pyelonephritis.

**Crystals:**
- Crystals found in freshly voided urine have more clinical significance than crystals seen in a urine sample that has been standing for more than 2 to 4 hr.
- Calcium oxalate crystals are found in ethylene glycol poisoning, urolithiasis, high dietary intake of oxalates, and Crohn’s disease.
- Cystine crystals are seen in patients with cystinosis or cystinuria.
- Leucine or tyrosine crystals may be seen in patients with severe liver disease.
- Large numbers of uric acid crystals are seen in patients with urolithiasis, gout, high dietary intake of foods rich in purines, or who are receiving chemotherapy (see monograph titled “Uric Acid, Urine”).

**CRITICAL VALUES:**
Possible critical values are the presence of uric acid, cystine, leucine, or tyrosine crystals.

The combination of grossly elevated urine glucose and ketones is also considered significant.

Note and immediately report to the health care provider (HCP) any critical values and related symptoms.

**INTERFERING FACTORS:**
- Certain foods, such as onion, garlic, and asparagus, contain substances that may give urine an unusual odor. An ammonia-like odor may be produced by the presence of bacteria. Urine with a maple syrup–like odor may indicate a congenital metabolic defect (maple syrup urine disease).
- The various biochemical strips are subject to interference that may produce false-positive or false-negative results. Consult the laboratory for specific information regarding limitations of the method in use and a listing of interfering drugs.
- The dipstick method for protein detection is mostly sensitive to the presence of albumin; light-chain or Bence Jones proteins may not be detected by this method. Alkaline pH may produce false-positive protein results.
- Large amounts of ketones or ascorbic acid may produce false-negative or decreased color development on the glucose pad. Contamination of the collection container or specimen with chlorine, sodium hypochlorite, or peroxide may cause false-positive glucose results.
- False-positive ketone results may be produced in the presence of ascorbic acid, levodopa metabolites, valproic acid, phenazopyridine, phenylketones, or phthalic acids.
• The hemoglobin pad may detect myoglobin, intact RBCs, and free hemoglobin. Contamination of the collection container or specimen with sodium hypochlorite or iodine may cause false-positive hemoglobin results. Negative or decreased hemoglobin results may occur in the presence of formalin, elevated protein, nitrite, ascorbic acid, or high specific gravity.

• False-negative nitrite results are common. Negative or decreased results may be seen in the presence of ascorbic acid and high specific gravity. Other causes of false-negative values relate to the amount of time the urine was in the bladder before voiding or the presence of pathogenic organisms that do not reduce nitrates to nitrites.

• False-positive leukocyte esterase reactions result from specimens contaminated by vaginal secretions. The presence of high glucose, protein, or ascorbic acid concentrations may cause false-negative results. Specimens with high specific gravity may also produce false-negative results. Patients with neutropenia (e.g., oncology patients) may also have false-negative results because they do not produce enough WBCs to exceed the sensitivity of the biochemical reaction.

• Specimens that cannot be delivered to the laboratory or tested within 1 hr should be refrigerated or should have a preservative added that is recommended by the laboratory. Specimens collected more than 2 hr before submission may be rejected for analysis.

• Because changes in the urine specimen occur over time, prompt and proper specimen processing, storage, and analysis are important to achieve accurate results. Changes that may occur over time include:
  - Production of a stronger odor and an increase in pH (bacteria in the urine break urea down to ammonia)
  - A decrease in clarity (as bacterial growth proceeds or precipitates form)
  - A decrease in bilirubin and urobilinogen (oxidation to biliverdin and urobilin)
  - A decrease in ketones (lost through volatilization)
  - Decreased glucose (consumed by bacteria)
  - An increase in bacteria (growth over time)
  - Disintegration of casts, WBCs, and RBCs
  - An increase in nitrite (overgrowth of bacteria)

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

磙  Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
磙  Inform the patient that the test is used to assist in the diagnosis of renal disease, urinary tract infections, and neoplasms of the urinary tract, and as an indication of systemic or inflammatory diseases.
磙  Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
磙  Obtain a history of the patient’s endocrine, genitourinary, immune, hematopoietic, hepatobiliary, and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
磙  Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
磙  Review the procedure with the patient. If a catheterized specimen is to be collected, explain this procedure to the patient, and obtain a catheterization tray. Address concerns about pain and explain that there should be no discomfort during the procedure. Inform the patient that specimen collection takes approximately 5 to 10 min.
磙  Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
磙  There are no food, fluid, or medication restrictions, unless by medical direction.

Access additional resources at davisplus.fadavis.com
**Suprapubic Aspiration:**
Place the patient in a supine position. Cleanse the area with antiseptic and drape with sterile drapes. A needle is inserted through the skin into the bladder. A syringe attached to the needle is used to aspirate the urine sample. The needle is then removed and a sterile dressing is applied to the site. Place the sterile sample in a sterile specimen container.

Do not collect urine from the pouch from the patient with a urinary diversion (e.g., ileal conduit). Instead, perform catheterization through the stoma.

**General:**
Include on the collection container’s label whether the specimen is clean catch or catheter and any medications that may interfere with test results.

Promptly transport the specimen to the laboratory for processing and analysis.

**Post-test:**
A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to report symptoms such as pain related to tissue inflammation, pain or irritation during void, bladder spasms, or alterations in urinary elimination.

Observe for signs of inflammation if the specimen is obtained by suprapubic aspiration.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Instruct the patient with a UTI, as appropriate, on the proper technique for wiping the perineal area (front to back) after a bowel movement. UTIs are more common in women who use diaphragm/spermicide contraception. These patients can be educated, as appropriate, in the proper insertion and removal of the contraceptive device to avoid recurrent UTIs.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient to begin antibiotic therapy, as prescribed, and instruct the patient in the importance of completing.
Uterine Fibroid Embolization

SYNONYM/ACRONYM: UFE.

AREA OF APPLICATION: Uterus.

CONTRAST: IV iodine based.

DESCRIPTION: Uterine fibroid embolization (UFE) is a way of treating fibroid tumors of the uterus. Fibroid tumors, also known as myomas, are masses of fibrous and muscle tissue in the uterine wall that are benign, but that may cause heavy menstrual bleeding, pain in the pelvic region, or pressure on the bladder or bowel. Using angiographic methods, a catheter is placed in each of the two uterine arteries, and small particles are injected to block the arterial branches that supply blood to the fibroids. The fibroid tissue dies, the mass shrinks, and the symptoms are relieved. This procedure, which is done under local anesthesia, is less invasive than open surgery done to remove uterine fibroids. Because the effects of uterine fibroid embolization on fertility are not yet known, the ideal candidate is a premenopausal woman with symptoms from fibroid tumors who no longer wishes to become pregnant. This technique is an alternative for women who do not want to receive blood transfusions or do not wish to receive general anesthesia. This procedure may be used to halt severe bleeding following childbirth or caused by gynecological tumors.

INDICATIONS:
- Treatment for anemia from chronic blood loss
- Treatment of fibroid tumors and tumor vascularity, for both single and multiple tumors
- Treatment of tumors in lieu of surgical resection

Access additional resources at davisplus.fadavis.com
RESULT:

Normal findings in:
• Decrease in uterine bleeding
• Decrease of pelvic pain or fullness

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
• Patients with allergies to shellfish or iodinated contrast medium. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
• Patients with bleeding disorders.
• Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
• Patients in whom cancer is a possibility or who have inflammation or infection in the pelvis.
• Elderly and other patients who are chronically dehydrated before the procedure, because of their risk of contrast-induced renal failure.
• Patients who are in renal failure.

Factors that may impair clear imaging:
• Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
• Retained barium from a previous radiological procedure
• Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

Other considerations:
• Complications of the procedure include hemorrhage, infection at the insertion site, and cardiac arrhythmias.
• The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
• Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.
• Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
• A small percentage of women may pass a small piece of fibroid tissue after the procedure. Women with this problem may require a procedure called a D&C (dilatation and curettage).
• Some women may experience menopause shortly after the procedure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses uterine and associated vascular function.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, anesthetics, or contrast medium.
Note any recent procedures that can interfere with test results; include examinations utilizing barium- or iodine-based contrast medium.

Obtain a history of the patient’s reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.

If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.

Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Explain that a sedative and/or anesthetic may be administered before the procedure to promote relaxation. Inform the patient that the procedure is performed in a radiology or vascular department by a HCP, with support staff, and takes approximately 30 to 120 min.

**Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. Explain that a sedative and/or anesthetic may be administered before the procedure to promote relaxation. Inform the patient that the procedure is performed in a radiology or vascular department by a HCP, with support staff, and takes approximately 30 to 120 min.

**INTRATEST:**

Ensure the patient has complied with dietary, fluids, and medication restrictions for 8 hr prior to the procedure.

Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.

If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.

Have emergency equipment readily available.

Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Record baseline vital signs and assess neurological status. Protocols may vary from facility to facility.

Establish standard precautions, and follow the general guidelines in Appendix A.

Establish an IV fluid line for the injection of emergency drugs and of sedatives.

Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to an uncooperative adult, as ordered.

Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.

Using a pen, mark the site of the patient’s peripheral pulses before angiography; this allows for quicker access to be examined prior to the procedure.

Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure.

Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary from facility to facility. Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.
and more consistent assessment of the pulses after the procedure.

Place the patient in the supine position on an exam table. Cleanse the selected area, and cover with a sterile drape.

The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to examine the vessels after a time and to monitor the venous phase of the procedure.

Ask the patient to inhale deeply and hold her breath while the x-ray images are taken, and then to exhale after the images are taken.

Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.

Particles are injected through the catheter to block the blood flow to the fibroids. The particles include polyvinyl alcohol, gelatin sponge (Gelfoam), and micospheres.

The needle or catheter is removed, and a pressure dressing is applied over the puncture site.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm). Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the HCP. Renal function should be assessed before metformin is resumed.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Patients may experience pelvic cramps for several days after the procedure and possible mild nausea and fever.

Advise the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.

Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation. Any pleuritic pain, persistent right shoulder pain, or abdominal pain should be reported to the appropriate HCP.

Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.

Recognize anxiety related to test results, and be supportive of impaired activity related to genitourinary system. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage her to review corresponding literature provided by a pharmacist.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include complete blood count, CT angiography, CT plevis, hysterosalpingography, laparoscopy, MRA, MRI pelvis, PT/INR, and US pelvis.

Refer to the Reproductive system table at the back of the book for related tests by body system.
Vanillylmandelic Acid, Urine

SYNONYM/ACRONYM: VMA.

SPECIMEN: Urine (25 mL) from a timed specimen collected in a clean plastic collection container with 6N hydrochloric acid as a preservative.

REFERENCE VALUE: (Method: High-pressure liquid chromatography)

<table>

DESCRIPTION: Vanillylmandelic acid (VMA) is a major metabolite of epinephrine and norepinephrine. It is elevated in conditions that also are marked by overproduction of catecholamines. Creatinine is usually measured simultaneously to ensure adequate collection and to calculate an excretion ratio of metabolite to creatinine.

INDICATIONS:
- Assist in the diagnosis of neuroblastoma, ganglioneuroma, or pheochromocytoma
- Evaluate hypertension of unknown cause

RESULT:

Increased in:
Catecholamine-secreting tumors will cause an increase in VMA.
- Ganglioneuroma
- Hypertension secondary to pheochromocytoma
- Neuroblastoma
- Pheochromocytoma

Decreased in: N/A

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs that may increase VMA levels include ajmaline, chlorpromazine, glucagon, guaifenesin, guanethidine, isoproterenol, methyldopa, nitroglycerin, oxytetracycline, phenazopyridine, phenolsulfonphthalein, prochlorperazine, rauwolfia, reserpine, sulfochromophthalein, and syrosingopine.
- Drugs that may decrease VMA levels include brofaromine, guanethidine, guanfacine, imipramine, isocarboxazid, methyldopa, monoamine oxidase inhibitors, morphine, nialamide (in schizophrenics), and reserpine.
- Stress, hypoglycemia, hyperthyroidism, strenuous exercise, smoking, and drugs can produce elevated catecholamines.
- Recent radioactive scans within 1 wk of the test can interfere with test results.
- Failure to collect all urine and store 24-hr specimen properly will result in a falsely low result.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the diagnosis and follow-up treatment of pheochromocytoma, neuroblastoma, and ganglioblastoma. It is also useful in evaluation and follow-up of hypertension.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device.
- Address concerns about pain and explain that there should be no discomfort during the procedure.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- There are no fluid restrictions unless by medical direction.

**INTRATEST:**
- Instruct the patient to abstain from smoking tobacco for 24 hr before testing.
- Inform the patient of the following dietary, medication, and activity restrictions in preparation for the test:
  - The patient should not consume foods high in amines for 48 hr before testing (bananas, avocados, beer, aged cheese, chocolate, cocoa, coffee, fava beans, grains, tea, vanilla, walnuts, and red wine).
  - The patient should not consume foods or fluids high in caffeine for 48 hr before testing (coffee, tea, cocoa, and chocolate).
  - The patient should not consume any foods or fluids containing vanilla or licorice.
  - The patient should avoid self-prescribed medications (especially aspirin) and prescribed medications (especially pyridoxine, levodopa, amoxicillin, carbidopa, reserpine, and disulfiram) for 2 wk before testing and as directed.
  - The patient should avoid excessive exercise and stress during the 24-hr collection of urine. Protocols may vary from facility to facility.
- Ensure that the patient has complied with dietary, medication, and activity restrictions and pretesting preparations prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date, and time of collection.
- **Timed Specimen:**
  - Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.

Nutritional considerations: Instruct the patient to avoid foods or drinks containing caffeine. Over-the-counter medications should be taken only under the advice of the patient’s HCP.

Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

Varicella Antibodies

SYNONYM/ACRONYM: Varicella-zoster antibodies, chickenpox, VZ.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

REFERENCE VALUE: (Method: Indirect fluorescent antibody) Negative or less than a fourfold increase in titer.

Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.

If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.

At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.

Include on the collection container’s label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.

Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Related tests include angiography adrenal, calcium, catecholamines, CT renal, homovanillic acid, metanephrines, and renin.

Refer to the Endocrine System table at the back of the book for related tests by body system.
**DESCRIPTION:** Varicella-zoster is a double-stranded DNA herpes virus that is responsible for two clinical syndromes, chickenpox and shingles. The incubation period is 2 to 3 wk, and it is highly contagious for about 2 wk beginning 2 days before a rash develops. It is transmitted in respiratory secretions. The primary exposure to the highly contagious virus usually occurs in susceptible school-age children. Adults without prior exposure and who become infected may have severe complications, including pneumonia. Neonatal infection from the mother is possible if exposure occurs during the last 3 wk of gestation. Shingles results when the presumably latent virus is reactivated. The presence of immunoglobulin (Ig) M antibodies indicates acute infection. The presence of IgG antibodies indicates current or past infection. A reactive varicella antibody result indicates immunity but does not protect an individual from shingles. There are also polymerase chain reaction methods that are capable of detecting varicella-zoster DNA in various specimen types.

**INDICATIONS:**
- Determine susceptibility or immunity to chickenpox

**RESULT:**
**Positive findings in:**
- Varicella infection

**Negative findings in:** N/A

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:** N/A

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to confirm diagnosis of varicella infection or immunity.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of exposure to varicella.
- Obtain a history of the patient’s immune and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm diagnosis. Any individual positive result should be repeated in 7 to 14 days to monitor a change in titer. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the
patient, and label the appropriate tube with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL red-top tube.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

**POST-TEST:**

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

**Vaccination considerations:** Record the date of last menstrual period and determine the possibility of pregnancy prior to administration of varicella vaccine to female varicella-nonimmune patients. Instruct patient not to become pregnant for 1 mo after being vaccinated with the varicella vaccine to protect any fetus from contracting the disease and having serious birth defects. Instruct on birth control methods to prevent pregnancy, if appropriate.

- Recognize anxiety related to test results, and provide emotional support if results are positive and the patient is pregnant. Inform the patient with shingles about access to pain management. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient in isolation precautions during the time of communicability or contagion. Emphasize the need to return to have a convalescent blood sample taken in 7 to 14 days. Provide information regarding vaccine-preventable diseases where indicated (e.g., encephalitis, hepatitis A and B, human papillomavirus, influenza, measles, mumps, polio, rubella, smallpox, varicella, yellow fever). Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Refer to the Immune and Reproductive System tables at the back of the book for related tests by body system.

---

**Venography, Lower Extremity Studies**

**SYNONYM/ACRONYM:** Phlebography, lower limb venography, venogram.

**AREA OF APPLICATION:** Veins of the lower extremities.

**CONTRAST:** IV iodine based.
**DESCRIPTION:** Venography allows x-ray visualization of the venous vasculature system of the extremities after injection of an iodinated contrast medium. Lower extremity studies identify and locate thrombi within the venous system of the lower limbs. After injection of the contrast medium, x-ray images are taken at timed intervals. Usually both extremities are studied, and the unaffected side is used for comparison with the side suspected of having deep vein thrombosis (DVT) or other venous abnormalities, such as congenital malformations or incompetent valves. Thrombus formation usually occurs in the deep calf veins and at the venous junction and its valves. If DVT is not treated, it can lead to femoral and iliac venous occlusion, or the thrombus can become an embolus, causing a pulmonary embolism. Venography is accurate for thrombi in veins below the knee.

**INDICATIONS:**
- Assess deep vein valvular competence
- Confirm a diagnosis of DVT
- Determine the cause of extremity swelling or pain
- Determine the source of emboli when pulmonary embolism is suspected or diagnosed
- Distinguish clot formation from venous obstruction
- Evaluate congenital venous malformations
- Locate a vein for arterial bypass graft surgery

**RESULT:**

*Normal findings in:* No obstruction to flow and no filling defects after injection of radiopaque contrast medium; steady opacification of superficial and deep vasculature with no filling defects

*Abnormal findings in:* Abnormal results may indicate DVT, deep vein valvular incompetence, or venous obstruction

**CRITICAL VALUES:**
- **DVT**
  Note and immediately report to the health care provider (HCP) abnormal results and related symptoms.

**INTERFERING FACTORS:**

*This procedure is contraindicated for:*
- Patients with allergies to shellfish or iodinated dye. The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother.
- Elderly and other patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- Patients who are in renal failure.
- Patients with bleeding disorders.

*Factors that may impair clear imaging:*
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Movement of the leg being tested, excessive tourniquet constriction, insufficient injection of contrast medium, and delay between injection and the x-ray
- Severe edema of the legs, making venous access impossible
Other considerations:

- Improper injection of the contrast medium that allows it to seep deep into the muscle tissue.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.
- Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures.

Personnel in the room with the patient should wear a protective lead apron or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure assesses the venous system of the lower extremities.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, and contrast medium.
- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- Obtain a history of the patient’s cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.

If contrast medium is scheduled to be used, patients receiving metformin (Glucophage) for non–insulin-dependent (type 2) diabetes should discontinue the drug on the day of the test and continue to withhold it for 48 hr after the test. Failure to do so may result in lactic acidosis.

Review the procedure with the patient. Address concerns about pain and explain to the patient that there may be moments of discomfort and some pain experienced during the procedure.

Inform the patient that the procedure is usually performed in a radiology or vascular suite by a HCP, with support staff, and takes approximately 30 to 60 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives. Usually normal saline is infused.

Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.

Inform the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.
INTRATEST:

- Ensure the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.
- Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
- Establish an IV fluid line for the injection of emergency drugs and of sedatives.
- Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.
- Using a pen, mark the site of the patient’s peripheral pulses before venography; this allows for quicker and more consistent assessment of the pulses after the procedure.
- Place the patient in the supine position on an exam table. Cleanse the selected area, and cover with a sterile drape.
- A local anesthetic is injected at the site, and a small incision is made or a needle inserted.
- The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined.

POST-TEST:

- A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to inhale deeply and hold his or her breathe while the x-ray images are taken, and then to exhale.
- Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.
- Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.
- Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation. Any pleuritic pain, persistent right shoulder pain, or abdominal pain should be reported to the appropriate HCP.
- Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema. Instruct the patient in the care and assessment of the site.
Instruct the patient to maintain bed rest for 4 to 6 hr after the procedure or as ordered.

**Nutritional considerations:** A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.

Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include alveolar/arterial gradient, angiography pulmonary, antibodies anticardiolipin, antithrombin III, blood gases, CT angiography, D-dimer, FDP, lactic acid, lung perfusion scan, lung ventilation scan, MRA, MRI abdomen, plethysmography, PT/INR, renogram, US peripheral Doppler, and US venous Doppler extremity studies.
- Refer to the Cardiovascular System table in the back of the book for related tests by body system.

**Vertebroplasty**

**SYNONYM/ACRONYM:** None.

**AREA OF APPLICATION:** Spine.

**CONTRAST:** None.

**DESCRIPTION:** Vertebroplasty is a minimally invasive, nonsurgical therapy used to repair a broken vertebra and to provide relief of pain related to vertebral compression in the spine that has been weakened by osteoporosis or tumoral lesions. Osteoporosis affects over 10 million women in the United States and accounts for over 700,000 vertebral fractures per year. This procedure is usually successful at alleviating the pain caused by a compression fracture less than 6 mo in duration with pain directly referable to the location of the fracture. Secondary benefits may include vertebra stabilization and reduction of the risk of further compression. This procedure is usually performed on an outpatient basis. The procedure involves injection of orthopedic cement mixture through a needle into a fracture site. Injection is visualized with guidance from radiological imaging. Vertebroplasty may be the preferred procedure when patients are too elderly or frail to tolerate open spinal surgery, or...
where bones are too weak for surgical repair. Patients with a malignant tumor may benefit from vertebroplasty. Other possible applications include younger patients whose osteoporosis is caused by long-term steroid use or a metabolic disorder. This procedure is recommended after basic treatments such as bed rest and orthopedic braces have failed, or when pain medication has been ineffective or caused the patient medical problems, including stomach ulcers.

INDICATIONS:
- Assist in the detection of nonmalignant tumors before surgical resection.
- Repair of compression spinal fractures of varying ages. Fractures older than 6 mo will respond but at a slower rate. Fractures less than 4 wk old should be given a chance to heal without intervention unless they are associated with disabling pain or hospitalization.
- Repair of spinal problems due to tumors.

RESULT:

Normal findings in:
- Improvement in the ability to ambulate without pain
- Relief of back pain

Abnormal findings in:
- Failure to reduce the patient’s pain
- Failure to improve the patient’s mobility

CRITICAL VALUES: N/A

INTERFERING FACTORS:

This procedure is contraindicated for:
- Patients with allergies to shellfish or iodinated dye.

The contrast medium used may cause a life-threatening allergic reaction. Patients with a known hypersensitivity to the contrast medium may benefit from premedication with corticosteroids or the use of nonionic contrast medium.
- Pain that is primarily radicular in nature
- Patients with bleeding disorders
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother
- Pain that is improving or that has been present and unchanged for years
- Imaging procedures that suggest no fracture is present or that the fracture is remote from the patient’s pain

Factors that may impair clear imaging:
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

Other considerations:
- Complications of the procedure include hemorrhage, infection at the insertion site, and cardiac arrhythmias.
- The procedure may be terminated if chest pain, or severe cardiac arrhythmias occur.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Consultation with a health care provider (HCP) should occur before
the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

**NURSING IMPLICATIONS AND PROCEDURE**

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure improves the spinal column function.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or contrast medium.
- Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- Obtain a history of the patient’s musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- Obtain a list of the patient’s current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix F). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in the radiology department by a HCP, with support staff, and takes approximately 30 to 90 min.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Explain that an IV line may be inserted to allow infusion of IV fluids, contrast medium, or sedatives. Usually normal saline is infused.
- Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary from facility to facility.
- Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.
- This procedure may be terminated if chest pain or severe cardiac arrhythmias occur.

**INTRATEST:**
- Ensure the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.
- Ensure the patient has removed all external metallic objects from the area to be examined.
- If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure.
- Have emergency equipment readily available.
- Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary from facility to facility.
Observe standard precautions, and follow the general guidelines in Appendix A.

Establish an IV fluid line for the injection of emergency drugs and of sedatives.

Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.

Place the patient in the prone position on an exam table. Cleanse the selected area, and cover with a sterile drape.

A local anesthetic is injected at the site, and a small incision is made or a needle inserted under fluoroscopy.

Orthopedic cement is injected through the needle into the fracture.

Ask the patient to inhale deeply and hold his or her breath while the images are taken, and then to exhale.

Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.

Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

The needle or catheter is removed, and a pressure dressing is applied over the puncture site.

Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

A report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.

Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the HCP. Renal function should be assessed before metformin is resumed.

Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Take temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.

Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, or decreased urinary output.

Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation. Any pleuritic pain, persistent right shoulder pain, or abdominal pain should be reported to the appropriate HCP.

Instruct the patient’s caregiver to apply cold compresses to the puncture site as needed, to reduce discomfort or edema. Instruct the patient and caregiver in the care and assessment of the site.

Instruct the patient to maintain bed rest for 4 to 6 hr after the procedure or as ordered.

Recognize anxiety related to test results, and be supportive of impaired activity related to physical activity. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include bone mineral densitometry, bone scan, CT spine, EMG, and MRI musculoskeletal.

Refer to the Musculoskeletal System table in the back of the book for related tests by body system.
**Visual Fields Test**

**SYNONYM/ACRONYM:** Perimetry, VF.

**AREA OF APPLICATION:** Eyes.

**CONTRAST:** N/A.

**DESCRIPTION:** The visual field (VF) is the area within which objects can be seen by the eye as it fixes on a central point. The central field is an area extending 25° surrounding the fixation point. The peripheral field is the remainder of the area within which objects can be viewed. This test evaluates the central VF, except within the physiological blind spot, through systematic movement of the test object across a tangent screen. It tests the function of the retina, optic nerve, and optic pathways. VF testing may be performed manually by the examiner (confrontation VF exam) or by using partially or fully automated equipment (tangent screen, Goldman, Humphrey VF exam). In the manual VF test the patient is asked to cover one eye and fix his or her gaze on the examiner. The examiner moves his or her hand out of the patient’s VF and then gradually brings it back into the patient’s VF. The patient signals the examiner when the hand comes back into view. The test is repeated on the other eye. The manual test is frequently used for screening because it is quick and simple. Tangent screen or Goldman testing is an automated method commonly used to create a map of the patient’s VF and is described in greater detail in this monograph.

**INDICATIONS:**
- Detect field vision loss and evaluate its progression or regression

**RESULT:**

**Normal findings in:**
- Normal central vision field will form a circle extending 25° superiorly, nasally, inferiorly, and temporally; 12° to 15° temporal to the central fixation point is a physiological blind spot, approximately 1.5° below the horizontal meridian. It is approximately 7.5° high and 5.5° wide. The patient should be able to see the test object throughout the entire central vision field except within the physiological blind spot.

**Abnormal findings in:**
- Amblyopia
- Blepharochalasis
- Blurred vision
- Brain tumors
- Cerebrovascular accidents
- Choroidal nevus
- Diabetes with ophthalmic manifestations
- Glaucoma
- Headache
- Macular degeneration
- Macular drusen
- Nystagmus
- Optic neuritis or neuropathy
- Ptosis of eyelid
- Retinal detachment, hole, or tear
- Retinal exudates or hemorrhage
- Retinal occlusion of the artery or vein
- Retinitis pigmentosa

Access additional resources at davisplus.fadavis.com
Subjective visual disturbance
Use of high-risk medications
VF defect
Vitreous traction syndrome

CRITICAL VALUES: N/A

INTERFERING FACTORS:

Factors that may impair the results of the examination:

- An uncooperative patient or a patient with severe vision loss who has difficulty seeing even a large vision screen may have test results that are invalid.
- Assess and make note of the patient’s cooperation and reliability as good, fair, or poor, because it is difficult to evaluate factors such as general health, fatigue, or reaction time that affect test performance.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the procedure detects visual field function.
- Obtain a history of the patient’s complaints, including a list of known allergens.
- Obtain a history of the patient’s known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Measurement of visual acuity with and without corrective lenses prior to testing is highly recommended. Instruct the patient to wear corrective lenses, if appropriate and if worn to correct for distance vision. Instruct the patient regarding the importance of keeping the eyes open for the test.
- Review the procedure with the patient. Address concerns about pain and explain that no discomfort will be experienced during the test. Inform the patient that a health care provider (HCP) performs the test, in a quiet, darkened room, and that to evaluate both eyes, the test can take up 30 min.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

- Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- Seat the patient 3 ft away from the tangent screen with the eye being tested directly in line with the central fixation tangent, usually a white disk, on the screen. Cover the eye that is not being tested. Ask the patient to place the chin in the chin rest and gently press the forehead against the support bar. Reposition the patient as appropriate to ensure the eye(s) to be tested are properly aligned in front of the VF testing equipment. While the patient stares at the disk on the screen the examiner will move an object toward the patient’s visual field. The patient signals the examiner when the object enters their visual field. The patient’s responses are recorded and a map of the patient’s VF, including areas of visual defect, can be drawn on paper manually or by a computer.

POST-TEST:

- A report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- Recognize anxiety related to test results, and encourage the patient to recognize and be supportive of impaired activity related to vision loss, perceived loss of driving privileges, or the possibility of requiring corrective lenses (self-image). Discuss the implications of the test results on the
patient’s lifestyle. Provide contact information, if desired, for a general patient education Web site on the topic of eye care (e.g., www.allaboutvision.com). Provide contact information regarding vision aids, if desired, for ABLEDATA (sponsored by the National Institute on Disability and Rehabilitation Research [NIDRR], available at www.abledata.com). Information can also be obtained from the American Macular Degeneration Foundation (www.macular.org), the Glaucoma Research Foundation (www.glaucoma.org), and the American Diabetes Association (www.diabetes.org).

Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**

- Related tests include fluorescein angiography, fructosamine, fundus photography, glucagon, glucose, glycated hemoglobin, gonioscopy, insulin, intraocular pressure, microalbumin, plethysmography, and slit-lamp biomicroscopy.
- Refer to the Ocular System table at the back of the book for related tests by body system.

**Vitamin B₁₂**

**SYNONYM/ACRONYM:** Cyanocobalamin.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** (Method: Immunochemiluminescent assay)

<table>
<thead>
<tr>
<th>Age</th>
<th>Conventional Units</th>
<th>SI Units (Conventional Units × 0.738)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Newborn–11 mo</td>
<td>160–1300 pg/mL</td>
<td>118–959 pmol/L</td>
</tr>
<tr>
<td>Adult</td>
<td>200–900 pg/mL</td>
<td>148–664 pmol/L</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Vitamin B₁₂ has a ringed crystalline structure that surrounds an atom of cobalt. It is essential in DNA synthesis, hematopoiesis, and central nervous system (CNS) integrity. It is derived solely from dietary intake. Animal products are the richest source of vitamin B₁₂. Its absorption depends on the presence of intrinsic factor. Circumstances that may result in
a deficiency of this vitamin include the presence of stomach or intestinal disease as well as insufficient dietary intake of foods containing vitamin B_{12}. A significant increase in red blood cell (RBC) mean corpuscular volume may be an important indicator of vitamin B_{12} deficiency.

**INDICATIONS:**
- Assist in the diagnosis of CNS disorders
- Assist in the diagnosis of megaloblastic anemia
- Evaluate alcoholism
- Evaluate malabsorption syndromes

**RESULT:**

**Increased in:**
- Increases are noted in a number of conditions; pathophysiology is not clear.
- Chronic granulocytic leukemia
- Chronic obstructive pulmonary disease
- Chronic renal failure
- Diabetes
- Leukocytosis
- Liver cell damage (hepatitis, cirrhosis) (*Stores in damaged hepatocytes will be released into circulation; synthesis of transport proteins is diminished by liver damage*)
- Obesity
- Polycythemia vera (*Pathophysiology is not well understood*)
- Protein malnutrition (*Lack of transport proteins will increase circulating levels*)
- Severe congestive heart failure
- Some carcinomas

**Decreased in:**
- Abnormalities of cobalamin transport or metabolism
- Bacterial overgrowth (*Vitamin will be consumed and utilized by the bacteria*)
- Crohn’s disease (*Related to poor absorption*)
- Dietary deficiency (e.g., in vegetarians)
- *Diphyllolobothrium* (fish tapeworm) infestation (*Vitamin will be consumed and utilized by the parasite*)
- Gastric or small intestine surgery (*Related to dietary deficiency or poor absorption*)
- Hypochlorhydria (*Ineffective digestion resulting in poor absorption*)
- Inflammatory bowel disease (*Related to dietary deficiency or poor absorption*)
- Intestinal malabsorption
- Intrinsic factor deficiency (*Required for proper vitamin B_{12} absorption*)
- Late pregnancy (*Related to dietary deficiency or poor absorption*)
- Pernicious anemia (*Related to dietary deficiency or poor absorption*)

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**
- Drugs that may increase vitamin B_{12} levels include chloral hydrate.
- Drugs that may decrease vitamin B_{12} levels include alcohol, aminosalicylic acid, anticonvulsants, ascorbic acid, cholestyramine, cimetidine, colchicine, metformin, neomycin, oral contraceptives, ranitidine, and triamterene.
- Hemolysis or exposure of the specimen to light invalidates results.
- Specimen collection soon after blood transfusion can falsely increase vitamin B_{12} levels.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to diagnose and monitor vitamin B₁₂ deficiency.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s gastrointestinal and hematopoietic systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to fast for at least 12 hr before specimen collection. Protocols may vary from facility to facility.
- There are no fluid or medication restrictions, unless by medical direction.

INTRATEST:
- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 12 hr prior to the procedure.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. Protect the specimen from light.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
- Instruct the patient to resume usual diet, as directed by the HCP.
- Nutritional considerations: Instruct the patient with a deficiency of vitamin B₁₂, as appropriate, in the use of vitamin supplements. Inform the patient, as appropriate, that the best dietary sources of vitamin B₁₂ are meats, fish, poultry, eggs, and milk.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
- Related tests include complete blood count, complete blood count, RBC count, complete blood count, RBC indices, complete blood count, RBC morphology, complete blood count, WBC count and differential, folate, gastric acid stimulation, gastrin stimulation, homocysteine, and intrinsic factor antibodies.
- Refer to the Gastrointestinal and Hematopoietic System tables at the back of the book for related tests by body system.
**Vitamin D**

**SYNONYM/ACRONYM:** Cholecalciferol, vitamin D 1,25-dihydroxy.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

**REFERENCE VALUE:** (Method: High-performance liquid chromatography)

<table>
<thead>
<tr>
<th>Form</th>

<tr>
<td>Vitamin D 1,25-dihydroxy</td>
<td>15–60 pg/mL</td>
<td>37.4–149.8 pmol/L</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** There are two metabolically active forms of vitamin D. Ergocalciferol (vitamin D₂) is formed when ergosterol in plants is exposed to sunlight. Ergocalciferol is absorbed by the stomach and intestine when orally ingested. Cholecalciferol (vitamin D₃) is formed when the skin is exposed to sunlight or ultraviolet light. Vitamins D₂ and D₃ enter the bloodstream after absorption. Vitamin D₃ is converted to vitamin D 25-dihydroxy by the liver and is the major circulating form of the vitamin. Vitamin D₂ is converted to vitamin D 1,25-dihydroxy by the kidneys and is the more biologically active form. Vitamin D acts with parathyroid hormone and calcitonin to regulate calcium metabolism and osteoblast function.

**RESULT:**

**Increased in:**
- Endogenous Vitamin D intoxication *(In conditions such as sarcoidosis, cat scratch disease, and some lymphomas, extrarenal conversion of 25-dihydroxy to 1,25-dihydroxy vitamin D occurs with a corresponding abnormal elevation of calcium.)*
- Exogenous Vitamin D intoxication

**Decreased in:**
- Bowel resection *(Related to lack of absorption)*
- Celiac disease *(Related to lack of absorption)*
- Inflammatory bowel disease *(Related to lack of absorption)*
- Malabsorption *(Related to lack of absorption)*
- Osteomalacia *(Related to dietary insufficiency)*
- Pancreatic insufficiency *(Lack of digestive enzymes to metabolize fat-soluble Vitamin D; malabsorption)*
- Rickets *(Related to dietary insufficiency)*
- Thyrotoxicosis *(Possibly related to increased calcium loss through sweat, urine, or feces)*

**INDICATIONS:**
- Differential diagnosis of disorders of calcium and phosphorus metabolism
- Evaluate deficiency or suspected toxicity
- Investigate bone diseases
- Investigate malabsorption
with corresponding decrease in Vitamin D levels)

CRITICAL VALUES:

Vitamin toxicity can be as significant as problems brought about by vitamin deficiencies. The potential for toxicity is especially important to consider with respect to fat-soluble vitamins, which are not eliminated from the body as quickly as watersoluble vitamins and can accumulate in the body. Most cases of toxicity are brought about by oversupplementing and can be avoided by consulting a qualified nutritionist for recommended daily dietary and supplemental allowances. Signs and symptoms of vitamin D toxicity include nausea, loss of appetite, vomiting, polyuria, muscle weakness, and constipation.

INTERFERING FACTORS:

• Drugs that may increase vitamin D levels include etidronate disodium and pravastatin.
• Drugs and substances that may decrease vitamin D levels include aluminum hydroxide, anticonvulsants, cholestyramine, colestipol, glucocorticoids, isoniazid, mineral oil, and rifampin.
• Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when radioimmunoassay is the test method.

INTERFERING FACTORS:

• If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
• Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
• Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
• Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
• Promptly transport the specimen to the laboratory for processing and analysis.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the test is used to evaluate vitamin D toxicity or deficiency.
• Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
• Obtain a history of the patient’s gastrointestinal and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
• Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
• Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
• Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
• There are no food, fluid, or medication restrictions, unless by medical direction.

POST-TEST:

• A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
• Nutritional considerations: Educate the patient with vitamin D deficiency, as appropriate, that the main dietary sources of vitamin D are fortified dairy foods and cod liver oil. Explain to the patient that vitamin D is also synthesized by the body, in the skin, and is activated by sunlight.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**Related Monographs:**
- Related tests include amylase, ANCA, biopsy intestinal, calcium, capsule endoscopy, colonoscopy, fecal analysis, fecal fat, antibodies gliadin antibodies, kidney stone panel, laparoscopy abdominal, lipase, osteocalcin, oxalate, phosphorus, and proctosigmoidoscopy.
- Refer to the Gastrointestinal and Musculoskeletal System tables at the back of the book for related tests by body system.

---

**Vitamin E**

**SYNONYM/ACRONYM:** Tocopherol.

**SPECIMEN:** Serum (1 mL) collected in a red- or tiger-top tube.

**REFERENCE VALUE:** (Method: High-performance liquid chromatography)

<table>
<thead>
<tr>
<th>Age</th>
<th>Conventional Units</th>
<th>SI Units (Conventional Units × 23.22)</th>

<td>14–23 micromol/L</td>
</tr>
<tr>
<td>Adult</td>
<td>0.5–1.8 mg/dL</td>
<td>12–42 micromol/L</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Vitamin E is a powerful fat-soluble antioxidant that prevents the oxidation of unsaturated fatty acids, which can combine with polysaccharides to form deposits in tissue. For this reason, vitamin E is believed to reduce the risk of coronary artery disease. Vitamin E reserves in lung tissue provide a barrier against air pollution and protect red blood cell (RBC) membrane integrity from oxidation. Oxidation of fatty acids in RBC membranes can result in irreversible membrane damage and hemolysis. Studies are in progress to confirm the suspicion that oxidation also contributes to the formation of cataracts and macular degeneration of the retina. Because vitamin E is found in a wide variety of foods, a deficiency secondary to inadequate dietary intake is rare.

**INDICATIONS:**
- Evaluate neuromuscular disorders in premature infants and adults
- Evaluate patients with malabsorption disorders
- Evaluate suspected hemolytic anemia in premature infants and adults
- Monitor patients on long-term parenteral nutrition
RESULT:

Increased in:
- Obstructive liver disease
- Vitamin E intoxication

Decreased in:
- Abetalipoproteinemia (Rare inherited disorder of fat metabolism resulting in poor absorption of fat and fat-soluble vitamin E)
- Hemolytic anemia (Vitamin E is an important antioxidant that protects RBC cell membranes from weakening; deficiencies can result in hemolysis)
- Malabsorption disorders, such as biliary atresia, cirrhosis, cystic fibrosis, chronic pancreatitis, pancreatic carcinoma, and chronic cholestasis

CRITICAL VALUES:

Vitamin toxicity can be as significant as problems brought about by vitamin deficiencies. The potential for toxicity is especially important to consider with respect to fat-soluble vitamins, which are not eliminated from the body as quickly as water-soluble vitamins and can accumulate in the body. Most cases of toxicity are brought about by oversupplementing and can be avoided by consulting a qualified nutritionist for recommended daily dietary and supplemental allowances.

INTERFERING FACTORS:
- Drugs that may increase vitamin E levels include anticonvulsants (in women).
- Drugs that may decrease vitamin E levels include anticonvulsants (in men).
- Exposure of the specimen to light decreases vitamin E levels, resulting in a falsely low result.
**POST-TEST:**

- A report of the results will be sent to the requesting healthcare provider (HCP), who will discuss the results with the patient.
- **Nutritional considerations:** Educate the patient with a vitamin E deficiency, if appropriate, that the main dietary sources of vitamin E are vegetable oils, whole grains, wheat germ, milk, eggs, meats, fish, and green leafy vegetables. Vitamin E is fairly stable at most cooking temperatures (except frying) and when exposed to acidic foods.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

** RELATED MONOGRAPHS:**

- Related tests include amylase, antibodies gliadin, biopsy bone marrow, biopsy intestinal, capsule endoscopy, colonoscopy, complement, complete blood count, complete blood count, hematocrit, complete blood count, hemoglobin, complete blood count, RBC count, complete blood count, RBC indices, and complete blood count, RBC morphology, Coomb’s antiglobulin direct and indirect, fecal analysis, fecal fat, Ham’s test, Hgb electrophoresis, laparoscopy abdominal, lipase, osmotic fragility, and proctosigmoidoscopy.
- Refer to the Cardiovascular, Gastrointestinal, Hematopoietic, and Hepatobiliary System tables at the back of the book for related tests by body system.

---

**Vitamin K**

**SYNONYM/ACRONYM:** Phyloquinone, phytonadione.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube.

**REFERENCE VALUE:** (Method: High-performance liquid chromatography)

<table>
<thead>
<tr>
<th>Conventional Units</th>
<th>SI Units (Conventional Units × 2.22)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.13–1.19 ng/mL</td>
<td>0.29–2.64 nmol/L</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Vitamin K is one of the fat-soluble vitamins. It is essential for the formation of prothrombin; factors VII, IX, and X; and proteins C and S. Vitamin K also works with vitamin D in synthesizing bone protein, and regulating calcium levels (see monograph titled “Vitamin D.”) Vitamin K levels are not often requested, but vitamin K is often prescribed as a medication. Approximately one-half of the body’s vitamin K is produced by intestinal bacteria; the other half is obtained from dietary sources. There are three forms of vitamin K: vitamin K_1_, or phyloquinone, which is found in foods; vitamin K_2_, or menaquinone, which is synthesized by intestinal bacteria; and vitamin K_3_, or menadione, which is the synthetic, water-soluble, pharmaceutical form of the vitamin. Vitamin K_3_ is two to three times more potent than the naturally occurring forms.
INDICATIONS:
Evaluation of bleeding of unknown cause (e.g., frequent nosebleeds, bruising).

RESULT:

**Increased in:**
- Excessive administration of vitamin K

**Decreased in:**
- Antibiotic therapy *(By decreasing intestinal flora)*
- Chronic fat malabsorption *(Due to lack of digestive enzymes and poor absorption)*
- Cystic fibrosis *(Due to lack of digestive enzymes and poor absorption)*
- Diarrhea (in infants) *(Increased loss in feces)*
- Gastrointestinal disease *(Related to malabsorption)*
- Hemorrhagic disease of the newborn *(Newborns normally have low levels of vitamin K. Neonates at risk are those who are not given a prophylactic vitamin K shot at birth or those receiving nutrition strictly from breast milk, which has less vitamin K than cow’s milk)*
- Hypoprothrombinemia *(Prothrombin is a vitamin K–dependent protein)*
- Liver disease *(Interferes with storage of vitamin K)*
- Obstructive jaundice *(Damages hepatocytes and interferes with storage of vitamin K)*
- Pancreatic disease *(Insufficient enzymes to metabolize vitamin K)*

CRITICAL VALUES:
Vitamin toxicity can be as significant as problems brought about by vitamin deficiencies. The potential for toxicity is especially important to consider with respect to fat-soluble vitamins, which are not eliminated from the body as quickly as water-soluble vitamins and can accumulate in the body. The naturally occurring forms, vitamin K₁ and K₂, do not cause toxicity. Signs and symptoms of vitamin K₃ toxicity include bleeding and jaundice. Possible interventions include withholding the source.

INTERFERING FACTORS:
Drugs and substances that may decrease vitamin K levels include antibiotics, cholestyramine, coumarin, mineral oil, and warfarin.

NURSING IMPLICATIONS AND PROCEDURE

**PRETEST:**
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assist in the evaluation of symptoms relating to chronic antibiotic therapy and investigation of bleeding of unknown etiology.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s hematopoietic and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

**INTRATEST:**
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the

Access additional resources at davisplus.fadavis.com
Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture. Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage. Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.

Nutritional considerations: Inform the patient with a vitamin K deficiency, as appropriate, that the main dietary sources of vitamin K are cabbage, cauliflower, spinach and other green leafy vegetables, pork, liver, soybeans, and vegetable oils. Instruct the patient to report bleeding from any areas of the skin or mucous membranes.

Inform the patient of the importance of taking precautions against bleeding or bruising, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of aspirin products, and avoidance of intramuscular injections.
Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:
Related tests include ALT, antithrombin III, AST, bilirubin, chloride sweat, complete blood count, fecal analysis, fecal fat, GGT, and PT/INR.
Refer to the Hematopoietic and Hepatobiliary System tables at the back of the book for related tests by body system.

**Vitamins A, B₁, B₆, and C**

**SYNONYM/ACRONYM:** Vitamin A: retinol, carotene; vitamin B₁: thiamine; vitamin B₆: niacin, pyroxidine, P-5'-P, pyridoxyl-5-phosphate; vitamin C: ascorbic acid.

**SPECIMEN:** Serum (1 mL) collected in a red-top tube each for vitamins A and C; plasma (1 mL) collected in a lavender-top (EDTA) tube each for vitamins B₁ and B₆.

**REFERENCE VALUE:** (Method: High-performance liquid chromatography)
**DESCRIPTION:** Vitamin assays are used in the measurement of nutritional status. Low levels indicate inadequate oral intake, poor nutritional status, or malabsorption problems. High levels indicate excessive intake, vitamin intoxication, or absorption problems. Vitamin A is a fat-soluble nutrient that promotes normal vision and prevents night blindness; contributes to growth of bone, teeth, and soft tissues; supports thyroxine formation; maintains epithelial cell membranes, skin, and mucous membranes; and acts as an anti-infection agent. Vitamins B<sub>1</sub>, B<sub>6</sub>, and C are water soluble. Vitamin B<sub>1</sub> acts as an enzyme and plays an important role in the Krebs cycle. Vitamin B<sub>6</sub> is important in heme synthesis and functions as a coenzyme in amino acid metabolism and glycogenolysis. It includes pyridoxine, pyridoxal, and pyridoxamine. Vitamin C promotes collagen synthesis, maintains capillary strength, facilitates release of iron from ferritin to form hemoglobin, and functions in the stress response.

**INDICATIONS:**

**Vitamin A:**
- Assist in the diagnosis of night blindness
- Evaluate skin disorders
- Investigate suspected vitamin A deficiency

**Vitamin B<sub>1</sub>:**
- Investigate suspected beriberi
- Monitor the effects of chronic alcoholism

**Vitamin B<sub>6</sub>:**
- Investigate suspected malabsorption or malnutrition
- Investigate suspected vitamin B<sub>6</sub> deficiency

**Vitamin C:**
- Investigate suspected metabolic or malabsorptive disorders
- Investigate suspected scurvy

**RESULT:**

**Increased in:**
- Vitamin A: Chronic kidney disease
  Idiopathic hypercalcemia in infants
  Vitamin A toxicity

**Decreased in:**
- Vitamin A: Abetalipoproteinemia *(Related to poor absorption)*

Carcinoid syndrome (Related to poor absorption)
Chronic infections (Deficiency in vitamin A decreases ability to fight infection)
Cystic fibrosis (Related to poor absorption)
Disseminated tuberculosis (Related to poor absorption)
Hypothyroidism (Condition decreases ability of beta carotene to convert to vitamin A)
Infantile blindness (Related to dietary deficiency)
Liver, gastrointestinal (GI), or pancreatic disease (Related to malabsorption or poor absorption)
Night blindness (Related to chronic dietary deficiency or lack of absorption)
Protein malnutrition (Related to dietary deficiency)
Sterility and teratogenesis (Related to dietary deficiency)
Zinc deficiency (Zinc is required for generation of vitamin A transport proteins)

• Vitamin B₁:
  Alcoholism (Related to dietary deficiency)
  Carcinoid syndrome (Related to dietary deficiency or lack of absorption)
  Hartnup disease (Related to dietary deficiency)
  Pellagra (Related to dietary deficiency)

• Vitamin B₆: (This vitamin is involved in many essential functions like nucleic acid synthesis, enzyme activation, antibody production, electrolyte balance, and RBC formation. Deficiencies result in a variety of conditions.)
  Alcoholism (Related to dietary deficiency)
  Asthma
  Carpal tunnel syndrome
  Gestational diabetes
  Lactation (Related to dietary deficiency and/or increased demand)
  Malabsorption
  Malnutrition

Neonatal seizures
Normal pregnancies (Related to dietary deficiency and/or increased demand)
Occupational exposure to hydrazine compounds (Enzymatic pathways are altered by hydrazines in a manner that increases excretion of vitamin B₆)
Pellagra (Related to dietary deficiency)
Pre-eclamptic edema
Renal dialysis
Uremia

• Vitamin C:
  Alcoholism (Related to dietary deficiency)
  Anemia (Related to dietary deficiency)
  Cancer (Related to dietary deficiency or lack of absorption)
  Hemodialysis (Vitamin C is lost during the treatment)
  Hyperthyroidism (Related to dietary deficiency and/or increased demand)
  Malabsorption
  Pregnancy (Related to dietary deficiency and/or increased demand)
  Rheumatoid disease
  Scurvy (Related to dietary deficiency or lack of absorption)

CRITICAL VALUES:
Vitamin toxicity can be as significant as problems brought about by vitamin deficiencies. The potential for toxicity is especially important to consider with respect to fat-soluble vitamins (A, D, E, and K), which are not eliminated from the body as quickly as water-soluble vitamins and can accumulate in the body. Most cases of toxicity are brought about by oversupplementing and can be avoided by consulting a qualified nutritionist for recommended daily dietary and supplemental allowances. Signs and symptoms of vitamin A toxicity may include headache, blurred vision, bone pain, joint pain, dry skin, and loss of appetite.

INTERFERING FACTORS:
• Drugs and substances that may increase vitamin A levels include
alcohol (moderate intake), oral contraceptives, and probucol.

- Drugs and substances that may decrease vitamin A levels include alcohol (chronic intake, alcoholism), allopurinol, cholestyramine, colestipol, mineral oil, and neomycin.
- Drugs that may decrease vitamin B₁ levels include glibenclamide, isoniazid, and valproic acid.
- Drugs that may decrease vitamin B₆ levels include amiodarone, anticonvulsants, cycloserine, disulfiram, ethanol, hydralazine, isoniazid, levodopa, oral contraceptives, penicillamine, pyrazinoic acid, and theophylline.
- Drugs and substances that may decrease vitamin C levels include acetylsalicylic acid, aminopyrine, barbiturates, estrogens, heavy metals, oral contraceptives, nitrosamines, and paraldehyde.
- Chronic tobacco smoking decreases vitamin C levels.
- Various diseases may affect vitamin levels (see Results section).
- Diets high in freshwater fish and tea, which are thiamine antagonists, may cause decreased vitamin B₁ levels.
- Long-term hyperalimentation may result in decreased vitamin levels.
- Exposure of the specimen to light decreases vitamin levels, resulting in a falsely low results.

### NURSING IMPLICATIONS AND PROCEDURE

**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to assess hypervitaminosis or deficiency.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

**INTRATEST:**

- Obtain a history of the patient’s GI, genitourinary, hepatobiliary, immune, and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

**Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Instruct the patient to fast for at least 12 hr before specimen collection for vitamin A.
- There are no fluid or medication restrictions, unless by medical direction.

**POST-TEST:**

- Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 12 hr prior to the vitamin A test.
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
**Nutritional considerations:** Educate the patient with a specific vitamin deficiency, as appropriate, regarding dietary sources of these vitamins. Advise the patient to ask a nutritionist to develop a diet plan recommended for his or her specific needs.

**Vitamin A:**
- The main source of vitamin A comes from carotene, a yellow pigment noticeable in most fruits and vegetables, especially carrots, sweet potatoes, squash, apricots, and cantaloupe. It is also present in spinach, collards, broccoli, and cabbage. This vitamin is fairly stable at most cooking temperatures, but it is destroyed easily by light and oxidation.

**Vitamin B₁:**
- Vitamin B₁ is the most stable with respect to the effects of environmental factors. It is found in meats, coffee, peanuts, and legumes. The body is also capable of making some vitamin B₁ by converting the amino acid tryptophan to niacin.

**Vitamin B₆:**
- Good sources of vitamin B₆ include meats (especially beef and pork), whole grains, wheat germ, legumes (beans, peas, lentils), potatoes, oatmeal, and bananas. As with other water-soluble vitamins, it is best preserved by rapid cooking, although it is relatively stable at most cooking temperatures (except frying) and when exposed to acidic foods. This vitamin is destroyed rapidly by light and alkalis.

**Vitamin C:**
- Citrus fruits are excellent dietary sources of vitamin C. Other good sources are green and red peppers, tomatoes, white potatoes, cabbage, broccoli, chard, kale, turnip greens, asparagus, berries, melons, pineapple, and guava. Vitamin C is destroyed by exposure to air, light, heat, or alkalis. Boiling water before cooking eliminates dissolved oxygen that destroys vitamin C in the process of boiling. Vegetables should be crisp and cooked as quickly as possible.

**General:**
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

**RELATED MONOGRAPHS:**
- Related tests include amylase, BUN, chloride sweat, complete blood count, creatinine, lipase, prealbumin, TSH, FT₄, and zinc.
- Refer to the Gastrointestinal, Genitourinary, Hepatobiliary, Immune, and Musculoskeletal System tables at the back of the book for related tests by body system.
**White Blood Cell Scan**

**SYNONYM/ACRONYM:** WBC imaging, inflammatory scan, labeled leukocyte scan, infection scintigraphy, labeled autologous leukocytes.

**AREA OF APPLICATION:** Whole body.

**CONTRAST:** IV radionuclide combined with white blood cells.

**DESCRIPTION:** Because white blood cells (WBCs) naturally accumulate in areas of inflammation, the WBC scan uses radiolabeled WBCs to help determine the site of an acute infection or confirm the presence or absence of infection or inflammation at a suspected site. A gamma camera detects the radiation emitted from the injected radionuclide, and a representative image of the radionuclide distribution is obtained and recorded or stored electronically. Because of its better image resolution and greater specificity for acute infections, the WBC scan has replaced scanning with gallium-67 citrate (Ga-67). Some chronic infections associated with pulmonary disease, however, may be better imaged with Ga-67. The WBC scan is especially helpful in detecting postoperative infection sites and in documenting lack of residual infection after a course of therapy.

**RESULT:**

**Normal findings in:**
- No focal localization of the radionuclide, along with some slight localization of the radionuclide within the reticuloendothelial system (liver, spleen, and bone marrow)

**Abnormal findings in:**
- Abscess
- Arthritis
- Infection
- Inflammation
- IBD
- Osteomyelitis

**CRITICAL VALUES:** N/A

**INTERFERING FACTORS:**

This procedure is contraindicated for:
- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the procedure far outweigh the risks to the fetus and mother

Factors that may impair clear imaging:
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Retained barium from a previous radiological procedure, which may inhibit visualization of an abdominal lesion
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

**INDICATIONS:**
- Aid in the diagnosis of infectious or inflammatory diseases
- Differentiate infectious from noninfectious process
- Evaluate the effects of treatment
- Evaluate inflammatory bowel disease (IBD)
- Evaluate patients with fever of unknown origin
- Evaluate postsurgical sites and wound infections
- Evaluate suspected infection of an orthopedic prosthesis
- Evaluate suspected osteomyelitis
• Other nuclear scans done within 48 hr and Ga-67 scans within 4 wk before the procedure
• Lesions smaller than 1 to 2 cm, which may not be detectable
• A distended bladder, which may obscure pelvic detail

Other considerations:
• Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
• Patients with a low WBC count may need donor WBCs to complete the radionuclide labeling process; otherwise, Ga-67 scanning should be performed instead.
• False-negative images may be a result of hemodialysis, hyperglycemia, hyperalimentation, steroid therapy, and antibiotic therapy.
• The presence of multiple myeloma or thyroid cancer can result in a false-negative scan for bone abnormalities.
• Consultation with a health care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
• Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should stand behind a shield or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, or anesthetics.
Obtain a history of the patient’s immune system, symptoms, and results of previously performed laboratory tests, diagnostic and surgical procedures.
Note any recent procedures that can interfere with test results, including barium examinations.
Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
Obtain a list of the medications the patient is taking, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix F). Note the last time and dose of medication taken.
Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department by a HCP and usually takes approximately 1 to 6 hr, and that delayed images are needed 24 hr later. The patient may leave the department and return later to undergo delayed imaging.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
Instruct the patient to remove jewelry and other metallic objects in the area to be examined.
There are no dietary or medication restrictions prior to the procedure, unless by medical direction.
Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
• Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
• Inform the patient that the procedure assesses the presence of inflammation or infection.
If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production. Instruct the patient to immediately flush the toilet, and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure. Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed. Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed. Related tests include angiography pulmonary, bone scan, colonoscopy, complete blood count, complete blood count, WBC count and differential, CT abdomen, CT pelvis, CT spine, culture (blood, skin, wound), ESR, fecal analysis, gallium scan, GI blood loss scan, KUB, MRI musculoskeletal, MRI pelvis, MRI spine, proctosigmoidoscopy, radiography bone, and US abdomen, US pelvis and vitamin D. Refer to the Immune System table in the back of the book for related tests by body system.
Zinc

SYNONYM/ACRONYM: Zn.

SPECIMEN: Serum (1 mL) collected in a trace element–free, royal blue–top tube.

REFERENCE VALUE: (Method: Atomic absorption spectrophotometry)

DESCRIPTION: Zinc is found in all body tissues, but the highest concentrations are found in the eye, bone, and male reproductive organs. Zinc is involved in RNA and DNA synthesis and is essential in the process of tissue repair. It is also required for the formation of collagen and the production of active vitamin A (for the visual pigment rhodopsin). Zinc also functions as a chelating agent to protect the body from lead and cadmium poisoning. Zinc is absorbed from the small intestine. Its absorption and excretion seem to be through the same sites as those for iron and copper. The body does not store zinc as it does copper and iron. Untreated zinc deficiency in infants may result in a condition called acrodermatitis enteropathica. Symptoms include growth retardation, diarrhea, impaired wound healing, and frequent infections. Adolescents and adults with zinc deficiency exhibit similar adverse effects on growth, sexual development, and immune function, as well as altered taste and smell, emotional instability, impaired adaptation to darkness, impaired night vision, tremors, and a bullous, pustular rash over the extremities.

INDICATIONS:
- Assist in confirming acrodermatitis enteropathica
- Evaluate nutritional deficiency
- Evaluate possible toxicity
- Monitor replacement therapy in individuals with identified deficiencies
- Monitor therapy of individuals with Wilson’s disease

RESULT:

Increased in:
Zinc is contained in and secreted by numerous types of cells in the body. Damaged cells release zinc into circulation and increase blood levels.
- Anemia
- Arteriosclerosis
- Coronary heart disease
- Primary osteosarcoma of the bone
Decreased in:
This trace metal is an essential component of enzymes that participate in protein and carbohydrate metabolism. It is involved in DNA replication, insulin storage, carbon dioxide gas exchange, cellular immunity and healing, promotion of body growth, and sexual maturity. Deficiencies result in a variety of conditions.

- Acrodermatitis enteropathica (Congenital abnormality that affects zinc uptake and results in zinc deficiency)
- AIDS
- Acute infections
- Acute stress
- Burns
- Cirrhosis
- Conditions that decrease albumin
- Diabetes
- Long-term total parenteral nutrition
- Malabsorption
- Myocardial infarction
- Nephrotic syndrome
- Nutritional deficiency
- Pregnancy
- Pulmonary tuberculosis

CRITICAL VALUES: N/A

INTERFERING FACTORS:
- Drugs that may increase zinc levels include auranofin, chlorthalidone, corticotropin, oral contraceptives, and penicillamine.
- Drugs that may decrease zinc levels include anticonvulsants, cisplatin, citrates, corticosteroids, estrogens, interferon, and oral contraceptives.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:
- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- Inform the patient that the test is used to evaluate disorders associated with abnormal zinc levels and monitor response to therapy.
- Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- Obtain a history of the patient’s gastrointestinal, hepatobiliary, immune, and musculoskeletal systems, symptoms, and results of previously performed laboratory tests, and diagnostic and surgical procedures.
- Obtain a list of the patient’s current medications, including herbs, nutritional supplements, and nutraceuticals.
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- There are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:
- If the patient has a history of allergic reaction to latex, avoid the use of equipment containing latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tube with the corresponding patient demographics, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:
- A report of the results will be sent to the requesting health care provider (HCP), who will discuss the results with the patient.
Nutritional considerations: Topical or oral supplementation may be ordered for patients with zinc deficiency. Dietary sources high in zinc include shellfish, red meat, wheat germ, and processed foods such as canned pork and beans and canned chili. Patients should be informed that diets high in phytates from whole grains, coffee, cocoa, or tea bin zinc and prevent it from being absorbed. Decreases in zinc also can be induced by increased intake of iron, copper, or manganese. Vitamin and mineral supplements with a greater than 3:1 iron/zinc ratio inhibit zinc absorption. Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.

Answer any questions or address any concerns voiced by the patient or family. Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

Related Monographs:
- Related tests include albumin, complete blood count, complete blood count, WBC and differential, copper, iron, and vitamin A.
- Refer to the Gastrointestinal, Immune, Hepatobiliary, and Musculoskeletal System tables at the back of the book for related tests by body system.
## Laboratory Tests Associated with the Auditory System

**Antibiotic Drugs—Aminoglycosides:** Amikacin, Gentamicin, Tobramycin; Tricyclic Glycopeptide: Vancomycin, 92–96  
**Culture, Bacterial, Anal/Genital, Ear, Eye, Skin, and Wound,** 492–497  
**Zinc,** 1234–1236

## Diagnostic Tests Associated with the Auditory System

- **Audiometry** hearing loss, 153–156  
- **Computed Tomography,** Brain, 416–420  
- **Evoked Brain Potentials,** 590–594  
- **Magnetic Resonance Imaging,** Brain, 836–839  
- **Otoscopy,** 905–907  
- **Spondee speech reception threshold,** 1071–1073  
- **Tuning fork tests,** 1122–1125

## Cardiovascular System

**Laboratory Tests Associated with the Cardiovascular System**

- **Anion gap,** 83–86  
- **Apolipoprotein A and B,** 140–143  
- **Aspartate aminotransferase,** 149–152  
- **Atrial natriuretic factor,** 152–153  
- **Blood gases,** 221–222

Diagnostic Tests Associated with the Hepatobiliary System

- Computed tomography, angiography, 412–416
- Computed tomography, liver, 412–416
- Hepatobiliary scan, 701–704
- Magnetic resonance angiography, 829–831, 836–839
- Magnetic resonance imaging, abdomen, 832–835
- Radiofrequency ablation, liver, 1024–1027
- Ultrasound, liver and biliary system, 1147–1149

Lab Tests Associated with the Immune System

### Acid Phosphatase
- Prostatic, 3–4
- (Available at Davis Plus website)

### Albumin
- 15–18

### Allergen-Specific Immunoglobulin E
- 26–28

### Amikacin
- 92–96

### Angiotensin-Converting Enzyme
- 82–83

### Anion Gap
- 83–86

### Antibodies
- Anticentromere, 104–108
- Anti-cyclic citrullinated peptide, 96–98
- Antineutrophilic cytoplasmic, 102–104
- DNA, 104–108
- Anti-glomerular basement membrane, 99–100
- Antimitochondrial and Antismooth Muscle, 100–102
- Antinuclear, 104–108
- Antiscleroderma, 104–108
- Antisperm, 108–110
- Antistreptolysin O, 110–111
- Antithyroglobin and Antithyroid Peroxidase, 112–113
- Cardiolipin, Immunoglobulin G and Immunoglobulin M, 113–115
- Gliadin (Immunoglobulin G and Immunoglobulin A), 115–117
- Antideoxyribonuclease-B, Streptococcal, 122–124
- Antigen/Antibodies, Antireactive nuclear, 104–108
- Biopsy, Bladder, 166–169
- Biopsy, Bone, 170–172
- Biopsy, Bone Marrow, 173–177
- Biopsy, Breast, 177–181
- Biopsy, Cervical, 182–185
- Biopsy, Intestinal, 188–190
- Biopsy, Kidney, 191–194
- Biopsy, Liver, 194–197
- Biopsy, Lung, 197–201
- Biopsy, Lymph Node, 202–205
- Biopsy, Muscle, 205–208
- Biopsy, Prostate, 208–211
- Biopsy, Skin, 212–214
- Biopsy, Thyroid, 215–217
- Bladder Cancer Markers, 218–219
- Blood Groups and Antibodies, 233–237
- Carcinoembryonic Antigen, 282–285
- CD4/CD8 Enumeration, 291–293
- Cerebrospinal Fluid Analysis, 293–298
- Chlamydia Group Antibody, 304–306
- Cold Agglutinin Titer, 341–343
- Complement C3 and Complement C4, 356–358
- Complement, Total, 359–360
- Complete Blood Count, 360–367
- Copper, 461–463
- C-Reactive Protein, 470–472
- Cryoglobulin, 485–486
- Culture and Smear, Mycobacteria, 487–492
- Culture, Bacterial, Anal/Genital, Ear, Eye, Skin, and Wound, 492–497
- Culture, Bacterial, Blood, 498–501
- Culture, Bacterial, Sputum, 501–506
- Culture, Bacterial, Stool, 506–509
- Culture, Bacterial, Throat or Nasopharyngeal, 509–511
- Culture, Bacterial, Urine, 511–514

### Diagnostic Tests Associated with the Musculoskeletal System

- Electroneurography, 570–572
- Evoked brain potentials, 590–594
- Magnetic resonance imaging, musculoskeletal, 847–850
- Positron emission tomography, brain, 962–966
- Positron emission tomography, fluorodeoxyglucose, 598–601
- Radiography, bone, 1027–1029
- Vertebroplasty, 1211–1214

### Nutritional Considerations

#### Laboratory Tests with Nutritional Considerations

- Albumin and Albumin/Globulin ratio, 15–18
- Calcium, Blood, 259–263
- Chloride, Blood, 306–310
- Cholesterol, HDL and LDL, 325–329
- Cholesterol, Total, 329–333
- Copper, 461–463
- Folate, 626–628
- Glucose, 657–672
- Insulin and Insulin Response to Glucose, 744–747
- Iron, 760–766
- Magnesium, Blood, 822–824
- Oxalate, Urine, 910–912
- Phosphorus, Blood, 939–942
- Potassium, Blood, 974–978
- Sodium, Blood, 1064–1067
- Triglycerides, 1108–1111
- Uric Acid, Blood, 1185–1188
- Vitamin B₁₂, 1217–1219
- Vitamin D, 1220
- Vitamin E, 1222–1224
- Vitamin K, 1224–1226
- Vitamins A, B₁, B₆, and C, 1226–1230

### Ocular System

#### Laboratory Tests Associated with the Ocular System

- Antibodies, Antinuclear, Anti-DNA, Anticentromere, Antiextractable Nuclear Antigen, and Antiscleroderma, 104–108
- Antiarrhythmic Drugs: Digoxin, Disopyramide, Flecaainide, Lidocaine, Procainamide, Quinidine, 86–92
- Anticonvulsant Drugs: Carbamazepine, Ethosuximide, Phenobarbital, Phenytoin, Primidone, Valproic Acid, 117–122
- C-Peptide, 467–469
- Cholesterol, Total, 329–333
- Culture, Bacterial, Anal/Genital, Ear, Eye, Skin, and Wound, 492–497
- Fructosamine, 631–633
- Glucagon, 654–657
- Glucose, 657–676
- Glycated Hemoglobin A₁c, 672–674
- Insulin and Insulin Response to Glucose, 744–747
- Microalbumin, 876–879
- Plethysmography, 950–954
- Rheumatoid Factor, 1049–1050
- Vitamins A, B₁, B₆, and C, 1226–1230

Patient Preparation and Specimen Collection

PATIENT PREPARATION BEFORE DIAGNOSTIC AND LABORATORY PROCEDURES

The first step in any laboratory or diagnostic procedure is patient preparation or patient teaching before the performance of the procedure. This pretesting explanation to the patient or caregiver follows essentially the same pattern for all sites and types of studies and includes the following:

• **Statement of the purpose of the study.** The level of detail provided to patients about the test purpose depends on numerous factors and should be individualized appropriately in each particular setting.

• **Description of the procedure, including site and method.** It is a good idea to explain to the patient that you will be wearing gloves throughout the procedure. The explanation should help the patient understand that the use of gloves is standard practice established for his or her protection as well as yours. Many institutions require hand washing at the beginning and end of each specimen collection encounter and between each patient.

• **Description of the sensations, including discomfort and pain, that the patient may experience during the specimen collection procedure.** Address concerns about pain related to the procedure and suggest breathing or visualization techniques to promote relaxation. For pediatric patients, a doll may be used to “show” the procedure. Where appropriate, the use of sedative or anesthetizing agents may assist in allaying anxiety the patient may experience that is related to anticipation of pain associated with the procedure. Sensitivity to cultural and social issues, as well as concern for modesty, is important in providing psychological support.

• **Instruction regarding pretesting preparations related to diet, liquids, medications, and activity as well as any restrictions regarding diet, liquids, medications, activity, known allergies, therapies, or other procedures that might affect test results.** To increase patient compliance, the instructions should include an explanation of why strict adherence to the instructions is required.

• **Recognition of anxiety related to test results.** Provide a compassionate, reassuring environment. Be prepared to educate the patient regarding access to the appropriate counseling services. Encourage the patient to ask questions and verbalize his or her concerns.

Specific collection techniques and patient preparation vary by site, study required, and level of invasiveness. These techniques are described in the individual monographs.

• It is essential that the patient be positively and properly identified before providing care, treatment, or services. Specimens should always be labeled with the patient’s name, date of birth, (or some other unique identifier), date collected, time collected, and initials of the person collecting the sample.

• Orders should be completed accurately and submitted per laboratory policy.

BLOOD SPECIMENS

Most laboratory tests that require a blood specimen use venous blood. Venous blood can be collected directly from the vein or by way of capillary puncture. Capillary blood can be obtained from the fingertips or earlobes of
adults and small children. Capillary blood can also be obtained from the heels of infants. The circumstances in which the capillary method would be selected over direct venipuncture include cases in which:

- The patient has poor veins.
- The patient has small veins.
- The patient has a limited number of available veins.
- The patient has significant anxiety about the venipuncture procedure.

Venous blood also can be obtained from vascular access devices, such as heparin locks and central venous catheters. Examples of central venous catheters include the triple-lumen subclavian, Hickman, and Groshong catheters.

Fetal blood samples can be obtained, when warranted, by a qualified health care provider (HCP) from the scalp or from the umbilical cord.

Arterial blood can be collected from the radial, brachial, or femoral artery if blood gas analysis is requested.

There are some general guidelines to be followed should follow in the procurement and handling of blood specimens:

- The practice of an overnight fast before specimen collection is a general recommendation. Reference ranges are often based on fasting populations to provide some level of standardization for comparison. Some test results are dramatically affected by foods, however, and fasting is a pretest requirement. The presence of lipids in the blood also may interfere with the test method; fasting eliminates this potential source of error, especially if the patient already has elevated lipid levels. The laboratory should always be consulted if there is a question as to whether fasting is a requirement or a recommendation.
- Gloves and any other additional personal protective equipment indicated by the patient’s condition should always be worn during the specimen collection process. Appendix G can be consulted for a more detailed description of standard precautions.
- Stress can cause variations in some test results. A sleeping patient should be gently awakened and allowed the opportunity to become oriented before collection site selection. Comatose or unconscious patients should be greeted in the same gentle manner because, although they are unable to respond, they may be capable of hearing and understanding. Anticipate instances in which patient cooperation may be an issue. Enlist the assistance of a second person to assist with specimen collection to ensure a safe, quality collection experience for all involved.
- Localized activity such as the application of a tourniquet or clenching the hand to assist in visualizing the vein can cause variations in some test results. It is important to be aware of affected studies before specimen collection.
- Hemoconcentration may cause variations in some test results. The tourniquet should never be left in place for longer than 1 minute.
- Previous puncture sites should be avoided when accessing a blood vessel by any means, to reduce the potential for infection.
- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. It is also possible that substances in the IV solution could contaminate the specimen and result in falsely elevated test results.
Changes in posture from supine to erect or long-term maintenance of a supine posture causes variations in some test results. It is important to be aware of this effect when results are interpreted and compared with previous values.

Collection times for therapeutic drug (peak and trough) or other specific monitoring (e.g., chemotherapy, glucose, insulin, or potassium) should be documented carefully in relation to the time of medication administration. It is essential that this information be communicated clearly and accurately to avoid misunderstanding of the dose time in relation to the collection time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause of subtherapeutic levels, toxic levels, and misleading information used in the calculation of future therapies.

The laboratory should be consulted regarding minimum specimen collection requirements when multiple tube types or samples are required. The amount of serum or plasma collected can be estimated using assumptions of packed cell volume or hematocrit. The packed cell volume of a healthy woman is usually 38% to 44% of the total blood volume. If a full 5-mL red-top tube is collected, and the hematocrit is 38% to 44%, approximately 2.8 to 3.1 mL, or \([5 - (5 \times 0.44)]\) to \([5 - (5 \times 0.38)]\), of the total blood volume should be serum. Factors that invalidate estimation include conditions such as anemia, polycythemia, dehydration, or overhydration.

The laboratory should be consulted regarding the preferred specimen container before specimen collection. Specific analytes may vary in concentration depending on whether the sample is serum or plasma. It is strongly recommended that, when serial measurements are to be carried out, the same type of collection container be used so that fluctuations in values caused by variations in specimen type are not misinterpreted as changes in clinical status. Consultation regarding collection containers is also important because some laboratory methods are optimized for a specific specimen type (serum versus plasma). Also, preservatives present in collection containers, such as sodium fluoride, may exhibit a chemical interference with test reagents that can cause underestimation or overestimation of measured values. Other preservatives, such as EDTA, can block the analyte of interest in the sample from participating in the test reaction, invalidating test results. Finally, it is possible that some high-throughput, robotic equipment systems require specific and standardized collection containers.

Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results. Specimens collected in containers with solid or liquid preservatives or with gel separators should be mixed by inverting the tube 10 times immediately after the tube has been filled. Handle the specimen gently to avoid hemolysis. Specimens should always be transported to the laboratory as quickly as possible after collection.

Results that are evaluated outside the entire context of the preparatory, collection, and handling process may be interpreted erroneously if consideration is not given to the above-listed general guidelines.

**Site Selection**

**Capillary Puncture:** Assess the selected area. It should be free of lesions and calluses, there should be no edema, and the site should feel warm. If the site
feels cool or if the site appears pale or cyanotic, warm compresses can be applied over 3 to 5 min to dilate the capillaries. For finger sticks, the central, fleshy, distal portions of the third or fourth fingers are the preferred collection sites (Figure Appendix A–1). For neonatal heel sticks, the medial and lateral surfaces of the plantar area are preferred to avoid direct puncture of the heel bone, which could result in osteomyelitis (Figure Appendix A–2).
Venipuncture of Arm: Assess the arm for visibly accessible veins. The selected area should not be burned or scarred, have a tattoo, or have hematoma present. Even after the tourniquet is applied, not all patients have a prominent median cubital, cephalic, or basilic vein. Both arms should be observed because some patients have accessible veins in one arm and not the other. The median cubital vein in the antecubital fossa is the preferred venipuncture site. The patient may be able to provide the best information regarding venous access if he or she has had previous venipuncture experience (Figure Appendix A–3). Alternative techniques to increase visibility of veins may include warming the arm, allowing the arm to dangle downward for a minute or two, tapping the antecubital area with the index finger, or massaging the arm upward from wrist to elbow. The condition of the vein also should be assessed before venipuncture. Sclerotic (hard, scarred) veins or veins in which phlebitis previously occurred should be avoided. Arms with a functioning hemodialysis access site should not be used. The arm on the affected side of a mastectomy should be avoided. In the case of a double mastectomy, the requesting HCP should be consulted before specimen collection.

Venipuncture of Hand and Wrist: If no veins in the arms are available, hands and wrists should be examined as described for the arm (Figure Appendix A–3). Consideration should be given to the venipuncture equipment selected because the veins in these areas are much smaller. Pediatric-sized collection containers and needles with a larger gauge may be more appropriate.

Venipuncture of Legs and Feet: The veins in the legs and feet can be accessed as with sites located on the arm, hand, or wrist. These extremities should be used only on the approval of the requesting HCP because veins in these locations are more prone to infection and formation of blood clots, especially in patients with diabetes, cardiac disease, and bleeding disorders.
Radial Arterial Puncture: The radial artery is the artery of choice for obtaining arterial blood gas specimens because it is close to the surface of the wrist and does not require a deep puncture. Its easy access also allows for more effective compression after the needle has been removed. The nearby ulnar artery can provide sufficient collateral circulation to the hand during specimen collection and postcollection compression (Figure Appendix A–4).

Percutaneous Umbilical Cord Sampling: The blood is aspirated from the umbilical cord under the guidance of ultrasonography and using a 20- or 22-gauge spinal needle inserted through the mother’s abdomen.

Postnatal Umbilical Cord Sampling: The blood is aspirated from the umbilical cord using a 20- or 22-gauge needle and transferred to the appropriate collection container.

Fetal Scalp Sampling: The requesting HCP makes a puncture in the fetal scalp using a microblade, and the specimen is collected in a long capillary tube. The tube is usually capped on both ends immediately after specimen collection.

Locks and Catheters: These devices are sometimes inserted to provide a means for the administration of fluids or medications and to obtain blood specimens without the need for frequent venipuncture. The device first should be assessed for patency. The need for heparinization, irrigation, or clot removal depends on the type of device in use and the institution-specific or HCP-specific protocols in effect. Use sterile technique because these devices provide direct access to the patient’s bloodstream. When IV fluids are being administered via a device at the time of specimen collection, blood should be

![Site selection. Arterial arm/hand.](image-url)
obtained from the opposite side of the body. If this is not possible, the flow should be stopped for 5 min before specimen collection. The first 5 mL of blood collected should be discarded.

**Selection of Blood Collection Equipment**

In many cases when a blood sample is required, serum is the specimen type of choice. Plasma may be frequently substituted, however. Specimen processing is more rapid for plasma samples than serum samples because the anticoagulated sample does not need to clot before centrifugation. Plasma samples also require less centrifugation time to achieve adequate separation. Consult with the testing laboratory regarding recommended specimen types. The basic blood collection tubes are shown on the inside cover of this book. Consider latex allergy when selecting the collection equipment appropriate for each patient. Equipment used in specimen collection includes:

- Gloves and other personal protective equipment depending on the situation
- Tourniquet
- Materials to cleanse or disinfect the collection site (alcohol preparations [70% alcohol], povidone-iodine solution [Betadine], or green soap are the most commonly used materials)
- Gauze (to wipe collection site dry after cleansing)
- Sterile lancet (capillary puncture)
- Syringe and needle (arterial puncture or venipuncture)
- Vial of heparin and syringe or heparin unit dose
- Sterile normal saline in 50-mL syringe (for indwelling devices such as Groshong catheter)
- Sterile cap or hub (for indwelling devices when the cap or hub will be replaced after specimen procurement)
- Needles and holder for vacuumized collection tube system (arterial puncture or venipuncture)
- Butterfly or winged infusion set (venipuncture)
- Collection container (vacuumized collection tube, capillary tube, or Microtainer)
- Bandage (to cover puncture site after specimen collection)

**Collection Procedure**

The procedures outlined here are basic in description. A phlebotomy or other text should be consulted for specific details regarding specimen collection and complications encountered during various types of blood collection. Positively identify the patient using at least two unique identifiers before providing care, treatment, or services. Label the appropriate tubes with the corresponding patient demographics, date, and time of collection before the specimen is collected. Obtain a history of the patient’s complaints, including a list of known allergens, especially allergies or sensitivities to latex.

**Capillary:** Place the patient in a comfortable position either sitting or lying down. Positively identify the patient using at least two unique identifiers before providing care, treatment, or services. Label the appropriate tubes with the corresponding patient demographics, date, and time of collection before the specimen is collected. Assess whether the patient has allergies to the disinfectant or to latex if latex gloves or tourniquet will be used in the collection procedure. Use gloved hands to select the collection site as
described in the site selection section. Cleanse the skin with the appropriate disinfectant and dry the area. Pull the skin tight by the thumb and index finger of the nondominant hand on either side of the puncture site and move them in opposite directions. Puncture the skin with a sterile lancet to a depth of approximately 2 mm, using a quick, firm motion. Wipe the first drop of blood away using the gauze. If flow is poor, the site should not be squeezed or the specimen may become contaminated with tissue fluid. Do not allow the collection container to touch the puncture site. Collect the sample in the capillary tube or Microtainer. The capillary tube should be held in a horizontal position to avoid the introduction of air bubbles into the sample. Microtainer tubes should be held in a downward-slanted direction to facilitate the flow of blood into the capillary scoop of the collection device. If a smear is required, allow a drop of blood to fall onto a clean microscope slide. Gently spread the drop across the slide using the edge of another slide. Apply slight pressure to the puncture site with a clean piece of gauze until bleeding stops, and then apply a bandage. Safely dispose of the sharps. Transport properly labeled specimens immediately to the laboratory.

**Venipuncture Using a Syringe or Vacuumized Needle and Holder System:** Place the patient in a comfortable position either sitting or lying down. Positively identify the patient using at least two unique identifiers before providing care, treatment, or services. Label the appropriate tubes with the corresponding patient demographics, date, and time of collection before the specimen is collected. Assess whether the patient has allergies to the disinfectant or to latex if latex gloves or tourniquet will be used in the collection procedure. Use gloved hands to select the collection site as described in the Site Selection section. Locate the vein visually, then by palpation using the index finger. The thumb should not be used because it has a pulse beat and may cause confusion in site selection or in differentiating a vein from an artery. Select the appropriate collection materials (needle size, butterfly, syringe, collection container size) based on the vein size, vein depth, appearance of the collection site, patient’s age, and anticipated level of cooperation. Cleanse the skin with the appropriate disinfectant and dry the area. Select the appropriate collection tubes. If blood cultures are to be collected, disinfect the top of the collection containers as directed by the testing laboratory. Be sure to have extra tubes within easy reach in case the vacuum in a collection tube is lost and a substitute is required. Apply the tourniquet 3 to 4 in. above the selected collection site. Remove the sterile needle cap, and inspect the tip of the needle for defects. Pull the skin tight by placing the thumb of the nondominant hand 1 or 2 in. below the puncture site and moving the thumb in the opposite direction. The thumb is placed below the puncture site to help avoid an accidental needle stick if the patient moves suddenly. Ensure that the needle is bevel up and held at an angle of approximately 15° to 30° (depending on the depth of the vein) (Figure Appendix A–5).

Puncture the skin with smooth, firm motion using a sterile needle held by the dominant hand. A reduction in pressure is achieved when the needle has penetrated the vein successfully. Be sure to release the tourniquet within 1 min of application. Fill the vacuumized collection containers in the prescribed order of draw for the studies ordered. Tubes with anticoagulants can be gently mixed with the free nondominant hand as they are filled. When the required containers have been filled, withdraw the needle and apply pressure to the collection site until the bleeding stops. In most cases, a piece of gauze can be placed on the collection site and the arm bent upward to hold it in
place while attention is given to disposing of the sharps safely. In cases in which a syringe is used, the barrel of the syringe should be gently pulled back during specimen collection and gently pushed in during the transfer to collection tubes. The vacuum in the collection container should not be allowed to suck the sample into the container, but rather the speed of entry should be controlled by the pressure applied to the barrel. The blood should gently roll down the side of the tube to prevent hemolysis. Transport properly labeled specimens immediately to the laboratory.

**Radial Artery Puncture:** Place the patient in a comfortable position either sitting or lying down. Positively identify the patient using at least two unique identifiers before providing care, treatment, or services. Label the appropriate tubes with the corresponding patient demographics, date, and time of collection before the specimen is collected. Assess whether the patient has allergies to the disinfectant or to latex if latex gloves or tourniquet will be used in the collection procedure. Assess if the patient has an allergy to local anesthetics, and inform the HCP accordingly. Glove the hands, and select the collection site as described in the site selection section. Ensure that the patient has adequate collateral circulation to the hand if thrombosis of the radial artery occurs after arterial puncture by performing an Allen test before puncture. The Allen test is performed by occlusion of the ulnar and radial arteries on the palmar surface of the wrist with two fingers. The thumb should not be used to locate these arteries because it has a pulse. Compress both arteries, and ask the patient to open and close the fist several times until the palm turns pale. Release pressure only on the ulnar artery. Color should return to the palm within 5 sec if the ulnar artery is functioning. If coloring returns above the wrist, the Allen test is positive. The Allen test also should be performed on the opposite hand. The wrist to which color is restored fastest has better circulation and should be selected as the site for blood gas collection. Be sure to explain to the patient that an arterial puncture is painful. The site may be anesthetized with 1% to 2% lidocaine (Xylocaine) before puncture. The index finger of the nondominant hand is placed over the site where the needle will enter the artery, not the site where the needle will penetrate the skin. The specimen is collected in an air-free heparinized syringe, which is held like a dart in the dominant hand and inserted slowly, bevel up, about 5 to 10 mm below the palpating finger at a 45° to 60° angle. When blood enters the needle hub, arterial pressure should cause blood to pump into the syringe. When enough specimen has been collected, the needle is withdrawn from the arm, and pressure is applied to the collection site for a minimum of 5 to 10 min. Immediately after the needle has been withdrawn safely from the arm, the exposed end of the syringe should be stoppered.

Samples should be gently and well mixed to ensure proper mixing of the heparin with the sample. The heparin prevents formation of small clots that result in rejection of the sample. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen
label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag. Transport properly labeled specimens immediately to the laboratory.

**Indwelling Devices:** Positively identify the patient using at least two unique identifiers before providing care, treatment, or services. Label the appropriate tubes with the corresponding patient demographics, date, and time of collection before the specimen is collected. Indwelling devices are either heparinized or irrigated after specimen collection. Before specimen collection, prepare the heparin in a syringe, if required. Allow the heparin (unit dose or prepared solution in the syringe) to equilibrate at room temperature during specimen collection. Cleanse the catheter cap or hub with povidone-iodine and 70% alcohol over 2 minutes. Using sterile gloves, remove the cap and attach a 5- or 10-mL syringe to the connector. Withdraw 5 mL of blood to be discarded. Clamp the catheter. (The Groshong catheter does not require clamping because it has a special valve that eliminates the need for clamping.) Attach another 5- or 10-mL syringe and begin collecting blood for transfer to the collection tubes. After the required specimen has been withdrawn, the device is heparinized by slowly injecting the heparin into the cap or hub of the device. Clamp the device 2 in. from the cap, remove the needle, and unclamp the device. Attach a new sterile cap or hub if the old one has been discarded. Groshong catheters are irrigated rather than heparinized. Irrigation of a Groshong catheter is accomplished by gently injecting 20 to 30 mL of sterile normal saline through the cap with moderate force. Remove the needle using some positive pressure (pressing down on the plunger) to prevent the solution from backing up into the syringe. Transport properly labeled specimens immediately to the laboratory.

**Order of Draw for Glass or Plastic Tubes (Reflects 2004 change in CLSI [formerly NCCLS] guideline: Recommended Order of Draw, H3-A5, [Vol 23, No 32, 8.10.2])**

*Note: Always follow your facility’s protocol for order of draw.*

- **First**—Blood culture and other tests requiring sterile specimen (yellow or yellow/black stopper); blood culture bottle first, followed by sodium polyethanol sulfonate (SPS) tube for acid-fast bacilli specimens.
- **Second**—Coagulation studies (light blue [sodium citrate] stopper); sodium citrate forms calcium salts to remove calcium, and this prevents specimen clotting. *Note:* When using a winged blood or vacutainer collection set and the blue-top tube is the first tube drawn, a nonadditive red-top or coagulation discard tube should be collected first and discarded. The amount of blood in the discard tube needs to be sufficient to fill the winged collection set tubing’s “dead space” or fill 1/4 of the discard tube. This is done to eliminate contamination of the specimen with tissue thromboplastin. The blue-top tube to be used for testing must be filled to ensure the proper ratio of blood to additive in the test specimen blue-top tube.
- **Third**—Plain or nonadditive (red or red/gray (gel) stopper); red/gray-top serum separator tube (SST) contains a gel separator and clot activator. SSTs are not appropriate for all testing requiring a serum specimen. They are generally unacceptable for therapeutic drug monitoring and serology studies. The laboratory should be consulted if there are questions regarding the use of SSTs.
- **Last**—Additive tubes in the following order:
Green stopper: tube contains sodium heparin or lithium heparin anticoagulant (heparin inactivates thrombin and thromboplastin, and this prevents specimen clotting). For ammonia levels, use sodium or lithium heparin. For lithium levels, use sodium heparin.

Lavender stopper: tube contains K₃ EDTA (tri-potassium EDTA forms calcium salts to remove calcium from the sample, and this prevents specimen clotting while preserving the integrity of the red blood cell wall).

Gray stopper: tube contains potassium oxalate/sodium fluoride (the potassium oxalate acts as an anticoagulant, and the sodium fluoride prevents glycolysis).

**URINE SPECIMENS**

The patient should be informed that improper collection, storage, and transport are the primary reasons for specimen rejection and subsequent requests for recollection. If the specimen is to be collected at home, it should be collected in a clean plastic container (preferably a container from the testing laboratory). Many studies require refrigeration after collection. If the collection container includes a preservative, the patient should be made aware of the contents and advised as to what the precaution labels mean (caution labels such as caustic, corrosive, acid, and base should be affixed to the container as appropriate). When a preservative or fixative is included in the container, the patient should be advised not to remove it. The patient also should be told not to void directly into the container. The patient should be given a collection device, if indicated, and instructed to void into the collection device. The specimen should be carefully transferred into the collection container. Urinary output should be recorded throughout the collection time if the specimen is being collected over a specified time interval. Some laboratories provide preprinted collection instructions tailored to their methods. The specimen should be transported promptly to the laboratory after collection.

Wear gloves and any other additional personal protective equipment indicated by the patient’s condition. See Appendix G for a more detailed description of standard precautions. Assess whether the patient has allergies to the disinfectant or anesthetic, or to latex if latex gloves or catheter will be used in the procedure.

**Random:** These samples are mainly used for routine screening and can be collected at any time of the day. The patient should be instructed to void either directly into the collection container (if there is no preservative) or into a collection device for transfer into the specimen container.

**First Morning:** Urine on rising in the morning is very concentrated. These specimens are indicated when screening for substances that may not be detectable in a more dilute random sample. These specimens are also necessary for testing conditions such as orthostatic proteinuria, in which levels vary with changes in posture.

**Second Void:** In some cases, it is desirable to test freshly produced urine to evaluate the patient’s current status, as with glucose and ketones. Explain to the patient that he or she should first void and then drink a glass of water. The patient should be instructed to wait 30 min and then void either directly into the collection container or into a collection device for transfer into the collection container.
**Clean Catch:** These midstream specimens are generally used for microbiological or cytological studies. They also may be requested for routine urinalysis to provide a specimen that is least contaminated with urethral cells, microorganisms, mucus, or other substances that may affect the interpretation of results. Instruct the male patient first to wash hands thoroughly, then cleanse the meatus, void a small amount into the toilet, and void either directly into the specimen container or into a collection device for transfer into the specimen container. Instruct the female patient first to wash hands thoroughly, and then to cleanse the labia from front to back. While keeping the labia separated, the patient should void a small amount into the toilet, and then, without interrupting the urine stream, void either directly into the specimen container or into a collection device for transfer into the specimen container.

**Catheterized Random or Clean Catch:** “Straight catheterization” is indicated when the patient is unable to void, when the patient is unable to prepare properly for clean-catch specimen collection, or when the patient has an indwelling catheter in place from which a urine sample may be obtained. Before collecting a specimen from the catheter, observe the drainage tube to ensure that it is empty, and then clamp the tube distal to the collection port 15 min before specimen collection. Cleanse the port with an antiseptic swab such as 70% alcohol and allow the port to dry. Use a needle and syringe (sterile if indicated) to withdraw the required amount of specimen. Unclamp the tube.

**Timed:** To quantify substances in urine, 24-hr urine collections are used. They are also used to measure substances whose level of excretion varies over time. The use of preservatives and the handling of specimens during the timed collection may be subject to variability among laboratories. The testing laboratory should be consulted regarding specific instructions before starting the test. Many times the specimen must be refrigerated or kept on ice throughout the entire collection period. Explain to the patient that it is crucial for all urine to be included in the collection. Urinary output should be recorded throughout the collection time if the specimen is being collected over a specified time interval. The test should begin between 6 and 8 a.m., if possible. Instruct the patient to collect the first void of the day and discard it. The start time of the collection period begins at the time the first voided specimen was discarded and should be recorded along with the date on the collection container. The patient should be instructed to void at the same time the following morning and to add this last voiding to the container. This is the end time of the collection and should be recorded along with the date on the container. For patients who are in the hospital, the urinary output should be compared with the volume measured in the completed collection container. Discrepancies between the two volumes indicate that a collection might have been discarded. Many times a creatinine level is requested along with the study of interest to evaluate the completeness of the collection.

**Catheterized Timed:** Instructions for this type of collection are basically the same as those for timed specimen collection. The test should begin by changing the tubing and drainage bag. If a preservative is required, it can be placed directly in the drainage bag, or the specimen can be removed at frequent intervals (every 2 hr) and transferred to the collection container to which the preservative has been added. The drainage bag must be kept on ice or emptied periodically into the collection container during the entire collection
period if indicated by the testing laboratory. The tubing should be monitored throughout the collection period to ensure continued drainage.

**Suprapubic Aspiration:** This procedure is performed by inserting a needle directly into the bladder. Because the bladder is normally sterile, the urine collected should also be free from any contamination caused by the presence of microorganisms. Place the patient in a supine position. Cleanse the area with antiseptic and drape with sterile drapes. A local anesthetic may be administered before insertion of the needle. A needle is inserted through the skin into the bladder. A syringe attached to the needle is used to aspirate the urine sample. The needle is then removed and a sterile dressing is applied to the site. Place the sterile sample in a sterile specimen container. The site must be observed for signs of inflammation or infection.

**Pediatric:** Specimen collection can be achieved by any of the above-described methods using collection devices specifically designed for pediatric patients. Appropriately cleanse the genital area and allow the area to dry. For a random collection, remove the covering of the adhesive strips on the collector bag and apply over the genital area. Diaper the child. When the specimen is obtained, place the entire collection bag in the specimen container (use a sterile container as appropriate for the requested study). Some laboratories may have specific preferences for the submission of urine specimens for culture. Consult the laboratory before collection to avoid specimen rejection.

**BODY FLUID, STOOL, AND TISSUE**
Wear gloves and any other additional personal protective equipment indicated by the patient’s condition. See Appendix G for a more detailed description of standard precautions. Assess whether the patient has allergies to the disinfectant or anesthetic, or to latex if latex gloves will be used in the procedure.

Specific collection techniques vary by site, study required, and level of invasiveness. These techniques are described in the individual monographs.

**DIAGNOSTIC TESTING**
Wear gloves and any other additional personal protective equipment indicated by the patient’s condition. See Appendix G for a more detailed description of standard precautions. Assess whether the patient has allergies to the disinfectant, anesthetic, contrast material, or medications, or to latex if latex gloves, catheter, or tourniquet will be used in the procedure.

A sleeping patient should be gently awakened and allowed the opportunity to become oriented before preparation for the selected study. Comatose or unconscious patients should be greeted in the same gentle manner because, although they are unable to respond, they may be capable of hearing and understanding. Anticipate instances in which patient cooperation may be an issue. Enlist the assistance of a second person to help with preparing the patient for the procedure to ensure a safe, quality testing experience for all involved.

Specific techniques and patient preparation vary by site, study required, and level of invasiveness. These techniques are described in the individual monographs.
Potential Nursing Diagnoses Associated with Laboratory and Diagnostic Testing

**PRETEST PHASE**
- Anxiety related to undiagnosed health problems
- Anxiety related to perceived threat to health status
- Anxiety and fear related to anticipated diagnostic results
- Anxiety and fear related to perception of diagnostic procedure as frightening or embarrassing
- Powerlessness related to unfamiliar procedure, equipment, environment, or personnel
- Knowledge deficit related to lack of information or possible misinterpretation of information provided about the procedure
- Knowledge deficit related to legal implications of testing
- Potential for noncompliance with test protocols related to inability to understand or follow instructions
- Potential for noncompliance with test protocols related to presence of high anxiety, confusion, or denial
- Potential for noncompliance with test protocols related to lack of knowledge or appropriate instruction
- Potential for noncompliance with test protocols related to confusion, weakness, and other individual factors

**INTRATEST PHASE**
- Risk for injury related to developmental age, psychological factors, and test procedures
- Risk for infection or allergic reaction related to altered immune function, history of chronic illness, allergens, or infectious agent
- Risk for latex allergy response associated with test equipment
- Pain, nausea, vomiting, or diarrhea related to laboratory and diagnostic procedures
- Injury, actual or risk for, related to invasive procedure associated with laboratory or diagnostic testing
- Risk for infection related to invasive procedures
- Risk for bleeding associated with altered bleeding tendencies related to invasive procedures
- Fatigue related to diagnostic procedure
- Anxiety and fear related to arterial puncture or venipuncture
- Risk for injury, bleeding, hematoma, or infection related to arterial puncture or venipuncture
- Pain related to arterial puncture or venipuncture
- Risk for impaired skin integrity
- Potential impairment of gas exchange associated with test procedure

**POST-TEST PHASE**
- Knowledge deficit related to significance of test results and potential need for further testing
- Knowledge deficit related to test outcome deviation that may necessitate medication or lifestyle alterations
- Anxiety and fear related to test outcome that may necessitate medication or lifestyle alterations
- Ineffective coping related to test outcome and potential for other interventional techniques or procedures
- Anticipatory grieving related to test outcome
- Anticipatory or actual grieving related to perceived loss of health or threat of death associated with diagnostic outcome
- Decisional conflict related to test outcome and potential for interventional procedures
- Potential alteration in tissue perfusion: cerebral, cardiopulmonary, or peripheral
- Knowledge deficit related to care after procedure
Guidelines for Age-Specific Communication

Effective communication between the health care provider and the patient is influenced by the patient’s cognitive abilities, sensory development or deprivation, level of stress, and environment. Effective communication with individuals at any stage of life is possible if one recognizes that it is essential to employ age-specific communication techniques based on an understanding of the continuum of human development as highlighted here.

### INFANT (BIRTH TO 1 YR)

**Physical**
- Rapid gains in height and weight
- Gradual shift from reflexive movements to intentional actions

**Motor and Sensory**
- Responds to light and sound
- Progresses to raising and turning head, bringing hand to mouth, rolling over, sitting upright, and standing

**Cognitive**
- Learns by imitation
- Progresses to recognize familiar objects and people
- Advances to speaking three or four words

**Psychosocial**
- Significant persons are parents or primary caregivers
- Develops sense of trust and security if needs are met
- May show fear of strangers
- May exhibit separation anxiety

**Interventions**
- Keep a parent or primary caregiver in view
- Involve significant persons in care if appropriate
- Provide consistency in health care staff to limit the number of strangers
- Face the infant when providing care
- Use soothing nonverbal communication, such as holding, rocking, and cuddling
- Assess immunizations
- Maintain safety and keep crib side rails up at all times

### TODDLER (1 TO 4 YR)

**Physical**
- Learning bladder and bowel control
- Temporary teeth erupt
- Physiological systems mature

**Motor and Sensory**
- Developing a higher level of manual dexterity (builds towers with blocks)
- Progresses to walking, jumping, and climbing
- Loves to experiment

**Cognitive**
- Has a short attention span
- Understands simple directions and requests

**Psychosocial**
- Significant persons are parents
- Asserts independence
- Understands ownership
- Attached to security objects
- Knows own gender
- Plays simple games

**Interventions**
- Face the toddler during interactions
- Give one direction at a time
- Tie words to action (toddlers learn by example)
- Use firm, direct approach; avoid harsh/excited words or actions
- Use distraction techniques
- Use soothing nonverbal communication, such as rocking, cuddling, and holding
- Communicate through play (dolls, puppets, music)
- Prepare shortly before a procedure
- Allow choices when possible
Encourage mother or parent to stay with the child as appropriate
Encourage parents to participate in care as appropriate
Maintain safety and keep crib side rails up at all times

CHILD (5 TO 12 YR)

Physical
Growth is slow and regular
Permanent teeth erupt
Pubescent changes start
May experience growing pains
May experience fatigue

Motor and Sensory
Skips and hops
Dresses and undresses independently
Throws and catches a ball
Uses common utensils and tools
Draws, paints, and likes quiet as well as active games

Cognitive
Major cognitive skill is communication
Understands numbers and can count
Constructs sentences and asks questions
Capable of logical thinking and can reason
Takes pride in accomplishments
Develops increased attention span

Psychosocial
Significant persons are parents, siblings, peers, teachers (prefers friends to family)
Increases independence and begins to assert self (may be physically aggressive)
Masters new tasks and acquires new skills
Behavior can be modified by rewards and punishment
Works hard to be successful

Interventions
Clearly define and reinforce behavior limits
Tell jokes and play games with rules
Check for special words used to identify parents, body parts, or body functions
Explain procedures in advance using correct terminology
Use dolls or puppets for explanations when performing procedures
Provide privacy
Involve whenever possible
Allow to have some control
Promote independence
Praise for good behavior
Acknowledge fear, pain, or family separation

ADOLESCENT (13 TO 18 YR)

Physical
Growth in skeletal size is rapid
Reproductive system matures
Vital signs approximate those of an adult

Motor and Sensory
Easily fatigued
May need more rest and sleep in early adolescence
Awkwardness in gross motor activity
Demonstrates improving fine motor skills

Cognitive
Increased ability to use abstract thought and logic
Able to handle hypothetical situations and thoughts
Shows growth in self-esteem but is challenged by bouts of insecurity
Avoids asking questions for fear of appearing unintelligent

Psychosocial
Develops sexual identity
Shows interest in and confusion with own development
Develops concern with physical appearance
Establishes critical need for privacy
Values belonging to peer group
Perceives self as invincible
Identity is threatened by hospitalization

Interventions
Likes to be treated like an adult
Do not talk to others about the patient in front of him or her
Do not ask questions about drugs, sex, or use of tobacco in front of parents
Provide information about routines and therapy
Provide privacy
Supplement information with rationale
Encourage questions
Allow to maintain control
Involve in decision making and care
Allow for expression of fear, such as fear of bodily injury and loss of control

ADULT (19 TO 65 YEARS)

Physical
Reaches physical and sexual maturity
Prone to health problems related to an inability to cope with new responsibilities
Health care needs related to preventive medicine
Adjustment to menopause (women) and sexual dysfunction (men) in middle adulthood

Motor and Sensory
Skills are fully developed

Cognitive
Focuses on time constraints and want to learn only what is practical for him or her
May be dual caregivers (i.e., parents and children)

Psychosocial
Experiences emotional stress secondary to mate selection, vocational selection, assuming occupational roles, marriage, childbearing, financial pressure, and independence

Interventions
Involve family in patient’s care and education
Explain benefits of adhering to treatment plan
Be honest and supportive
Respect personal values
Provide privacy
Keep a hopeful attitude
Focus on strengths, and not limitations
Recognize that unknown factors may affect behavior
Encourage patient to ask questions and talk about concerns
Provide information and support to make health care decisions

GERIATRIC (65 AND OLDER)

Physical
Ages gradually and individually
Experiences decreased tolerance to heat/cold
Encounters declining cardiac and renal function
Experiences skeletal changes (bones become more prominent, shrinkage in vertebral disks, stiff joints)
Becomes subject to increased susceptibility to infection and to high blood pressure
Undergoes skin changes

Motor and Sensory
Experiences decrease in mobility, visual acuity, ability to respond to stimuli, hearing, and motor skills

Cognitive
Experiences decrease in memory, slowing of mental functions, slowness in learning, and drop in performance

Psychosocial
Encounters lifestyle changes secondary to children leaving home, children providing grandchildren, re-establishing a relationship as a couple, and retirement/hobbies
Develops increased concern for health and financial security
Accepts concept of own mortality
Faces decreased authority and autonomy
Experiences depression related to decreased physical, motor, and cognitive abilities

Interventions
Explain instructions well to patient and family
Ask questions to verify understanding
Review important points repeatedly
Keep room clutter-free and call bell within reach
Control room temperature for comfort
Consider additional lighting at night
Watch for signs of drug toxicity
Give respect and provide privacy
Focus on strengths, and not limitations
Avoid assuming loss of abilities
Seek information as necessary to deal with impairments
Include patient in conversation/activity to prevent social isolation
Encourage to talk about feelings
Use humor and stay positive

Provide information and support regarding end-of-life decisions
Provide teaching for safety
Provide teaching for medications and test preparations
Transfusion Reactions: Laboratory Findings and Potential Nursing Interventions

These reactions are mainly associated with the transfusion of leuko-reduced packed red blood cells.

**CATEGORIES:**

I. Acute (Less than 24 hr)
   - Immune-Mediated Transfusion Reactions
     a. ABO and non-ABO acute hemolytic
     b. Febrile nonhemolytic
     c. Urticarial/allergic reaction
     d. Anaphylactic reaction

II. Acute (Less than 24 hr)
   - Non–Immune-Mediated Transfusion Reactions
     a. Transfusion-related acute lung injury
     b. Circulatory overload
     c. Metabolic complications
     d. Hypothermia
     e. Hypotension associated with angiotensin-converting enzyme inhibition
     f. Embolism (air and particulate)
     g. Nonimmune hemolysis

III. Delayed (Greater than 24 hr)
   - Immune-Mediated Transfusion Reactions
     a. Hemolytic
     b. Alloimmunization to red blood cell, white blood cell, platelet, and protein antigens
     c. Graft versus host

IV. Delayed (Greater than 24 hr)
   - Non–Immune-Mediated Transfusion Reactions
     a. Iron overload

---

### I. Acute Immune-Mediated Transfusion Reactions

**a. ABO and non-ABO acute hemolytic**

- **Dramatic, severe, and can be fatal; incidence 1:38,000 to 1:70,000 units; result of reaction between antibodies in the patient’s plasma and the corresponding antigen being present on the donor’s cells; severity affected by amount of patient antibody present, quantity of antigen on transfused cells, volume of blood transfused**

- **Symptoms**
  - Fever, chills, hypotension, tachycardia, nausea, vomiting, lower back pain, hemoglobinuria, renal failure with oliguria, flushing, generalized bleeding, pain or oozing at the infusion site

- **Lab Findings**
  - Positive DAT; elevated: indirect bilirubin (5 to 7 hr post-transfusion), LDH, BUN, creatinine, PT, aPTT; decreased: anti-A and anti-B titers, haptoglobin; hemoglobinemia; hemoglobinuria; hypofibrinogenemia; thrombocytopenia; positive urinary hemosiderin; presence of spherocytes and RBC fragments on peripheral smear

*(table continues on page 1270)*

</table>

**b. Circulatory overload**

| Symptoms | Dyspnea, orthopnea, cough, tachycardia, hypertension, headache |
| Lab Findings | N/A |
| Treatment | Upright posture; oxygen; diuretic; administer blood slowly; phlebotomy (250-mL increments) |

**c. Metabolic complications**

| Symptoms | Paresthesia, tetany, arrhythmia |
| Lab Findings | Elevated ionized calcium level, prolonged Q-T interval on EKG |
| Treatment | Slow calcium infusion, oral calcium supplement for mild symptoms; monitor ionized calcium levels (severe symptoms) |

**d. Hypothermia**

| Symptoms | Cardiac arrhythmia |
| Lab Findings | N/A |
| Treatment | Utilize blood warmer |

**e. Hypotension associated with ACE inhibition**

| Symptoms | Flushing, hypotension |
| Lab Findings | Positive DAT, hemolyzed intra- or post-transfusion specimen |
| Treatment | Avoid bedside leukocyte filtration |

**f. Embolism (air and particulate)**

| Symptoms | Sudden shortness of breath; acute cyanosis; pain; cough; hypotension; cardiac arrhythmia |
| Lab Findings | N/A |
| Treatment | Position patient on left side with legs elevated above head and chest |

**g. Nonimmune hemolysis**

| Symptoms | Hemoglobinuria |
| Lab Findings | Positive plasma-free hemoglobin, positive DAT, obvious hemolysis in unit containing the blood |
| Treatment | Identify and eliminate cause |

*(table continues on page 1272)*
### III. Delayed Immune-Mediated Transfusion Reactions

**a. Hemolytic**
- **Symptoms:** Anamnestic immune response to RBC antigens; incidence 1:11,000 to 1:50,000
- **Lab Findings:** Fever, anemia, mild jaundice
- **Treatment:** Positive antibody screen, urinary hemosiderin and DAT; increased LDH, bilirubin
- **Lab Findings:** Identify antibody and transfuse compatible blood as needed

**b. Alloimmunization to RBC, WBC, platelet, and protein antigens**
- **Symptoms:** Immune response to RBC, WBC, or platelet antigens; incidence 1:100
- **Lab Findings:** Delayed hemolytic reaction
- **Treatment:** Positive antibody screen and DAT
- **Lab Findings:** Avoid unnecessary transfusions; give leukocyte-reduced blood if transfusion is necessary

**c. Graft versus host**
- **Symptoms:** Donor lymphocytes attack recipient’s host tissue; incidence is rare
- **Lab Findings:** Erythroderma, maculopapular rash, anorexia, nausea, vomiting, diarrhea, hepatitis, pancytopenia, fever
- **Lab Findings:** Abnormal skin biopsy, incompatible HLA typing
- **Treatment:** Methotrexate, corticosteroids; transfuse with irradiated blood products

### IV. Delayed Non–Immune-Mediated Transfusion Reactions

**a. Iron overload**
- **Symptoms:** Result of chronic transfusions (greater than 100)
- **Lab Findings:** Symptoms associated with diabetes, cirrhosis, cardiomyopathy
- **Treatment:** Increased iron levels
- **Treatment:** Desferoxamine

---

ACE = angiotensin-converting enzyme; BUN = blood urea nitrogen; DAT = (Coombs’) direct antiglobulin test; DIC = disseminated intravascular coagulation; ECG = electrocardiogram; HLA = human leukocyte antigen; Ig = immunoglobulin; LDH = lactate dehydrogenase; N/A = not applicable; PT = prothrombin time; PTT = partial thromboplastin time; RBC = red blood cell; WBC = white blood cell.
Introduction to CLIA 1988 & 1992

The acronym CLIA stands for Clinical Laboratory Improvement Amendments. In 1988, Congress passed CLIA in order to establish quality standards that would apply to laboratory testing nationwide. The standards ensure that, regardless of location, all clinical testing on human specimens is performed with accuracy, reliability, and timeliness. In 1992, CLIA’s final regulations distinguished between levels of test complexity. Three categories were established: waived complexity, moderate complexity (includes the subcategory of Provider-Performed Microscopy [PPM]), and high complexity testing. Permission to perform clinical laboratory testing in any or all categories requires the laboratory director to submit an application to enroll in the CLIA program, pay the applicable fee, and meet quality requirements that correspond to the type of certificate that is obtained. The 10–1–04 edition of 42 CFR Ch. IV, the most current revision of CLIA, is the source used to write this introduction.

A Certificate of Waiver (COW) obtained by the appropriate health care provider (HCP) allows qualified nursing or other health care personnel to perform procedures classified as waived testing in a HCP’s office or in a hospital nursing unit. Waived testing includes tests that are cleared by the Food and Drug Administration (FDA) for home use, have manufacturers’ instructions to follow, and pose no harm to the patient if testing is performed incorrectly. The testing process utilizes controls. Examples of waived testing include dipstick urinalysis, fecal occult blood, ovulation testing, urine pregnancy tests, erythrocyte sedimentation rate (nonautomated), hemoglobin (copper sulfate method), blood glucose (on glucose meters cleared by the FDA), spun hematocrit, and hemoglobin by single analyte instruments that are self contained with direct measurement and readout.

PPM laboratories perform moderately complex testing. This type of testing can be performed in a HCP’s office. A PPM certificate obtained by a physician or midlevel practitioner allows the practitioner to perform moderately complex testing on specimens obtained during the patient’s office visit, in addition to waived testing. A midlevel practitioner can perform this type of testing under the direct supervision of a physician or in independent practice if authorized by the State. A microscope is utilized to view the specimens during the patient’s office visit. These moderately complex tests are performed on specimens in situations in which the accuracy of the findings would be compromised if a delay in testing were to occur. The testing process has no available controls. Examples of PPM testing include urine sediment examinations, potassium hydroxide preparations, pinworm examinations, fern tests, nasal smears for granulocytes, fecal leukocyte examinations, qualitative semen analysis (limited to determining the presence or absence of sperm and detection of motility), post coital direct, qualitative examinations of vaginal or cervical mucus, and wet mount testing for the presence or absence of bacteria, fungi, parasites, and cellular elements.

Hospital and reference laboratories perform tests of high complexity. The laboratory director must obtain the corresponding CLIA certificate and have personnel qualified to perform tests of high complexity.
Effects of Natural Products on Laboratory Values

The use of natural products has increased significantly, but to date, their preparation is unregulated. Their actions can affect normal and abnormal physiologic processes as well as interact with prescription medications. Their presence in the body, alone or in combination with over-the-counter products or prescription medications, may physiologically affect the intended target or cause analytical interference in such a way that the test result is affected. For this reason, it is important to note their use. The natural products listed here are contraindicated or are recommended for use with caution in patients with body system disorders or patients taking medications for these disorders. The requesting health care provider (HCP) and laboratory should be advised if the patient is regularly using these products so that their potential effects can be taken into consideration when reviewing results.

This list is not all-inclusive. Questions regarding the potential benefits and contraindications of natural products should be referred to the appropriate HCP. As a general recommendation, natural products and nutraceuticals are contraindicated during pregnancy and lactation.

### Natural Products That May Affect Cardiovascular Disorders or Interact with Therapeutics (Including Hypertension and Hypotension)

Adonis
Aloe
Bromelain
Buckthorn
Cascara
Chinese rhubarb
Coleus
Dong quai
Elder
Ephedra
Ergot
Frangula
Garlic
Ginseng
Goldenseal
Green tea (with caffeine)
Henbane
Horsetail
Lily of the valley
Ma-huang
Reishi
Senna
Squill
Tylophora
Valerian
Yohimbe bark

### Natural Products and Nutraceuticals That May Affect Endocrine Disorders or Interact with Therapeutics

#### Natural Products

Bilberry
Bitter melon
Bladderwrack
Bluplurum
Bugleweed
Echinacea
Ephedra
Fenugreek
Garcinia
Garlic
Ginseng
Goat’s rue
Green tea (with caffeine)
Guggul
Licorice
Marshmallow
Olive leaf
Psyllium
Tylophora

#### Minerals

Chromium
Nutraceuticals
Dehydroepiandrostosterone
a-Lipoic acid
Para-aminobenzoic acid
Thyroid extract

NATURAL PRODUCTS AND NUTRACEUTICALS THAT MAY AFFECT GASTROINTESTINAL DISORDERS OR INTERACT WITH THERAPEUTICS

Natural Products
- Bromelain
- Cascara
- Chinese rhubarb
- Dandelion
- Psyllium
- Senna
- Nutraceuticals
- Betaine hydrochloride

NATURAL PRODUCTS AND NUTRACEUTICALS THAT MAY AFFECT GENITOURINARY DISORDERS OR INTERACT WITH THERAPEUTICS

Natural Products
- Aloe
- Arabinoxylane
- Bladderwrack
- Buckthorn
- Cascara
- Chinese rhubarb
- Dandelion
- Echinacea
- Ephedra
- Ergot
- Frangula
- Ginseng
- Guarana
- Horse chestnut
- Horsetail
- Licorice
- Parsley oil (high doses)
- Saw palmetto
- Senna
- Stinging nettle
- White oak
- White willow
- Nutraceuticals
- Creatine
- Modified citrus pectin

Natural Products
- Arnica
- Astragalus
- Bilberry
- Bromelain
- Cat’s claw
- Cayenne
- Coleus
- Cordyceps
- Devil’s claw
- Dong quai
- Evening primrose
- Feverfew
- Garlic
- Ginger
- Gingko
- Ginseng
- Grape seed
- Green tea (with caffeine)
- Guggui
- Horse chestnut
- Papaya
- Red clover
- Red yeast rice
- Reishi
- Turmeric
- White willow
- Nutraceuticals
- Docosahexaenoic acid (DHA)
- Fish oils (the omega-3 fatty acids: EPA and DHA)

NATURAL PRODUCTS AND NUTRACEUTICALS THAT MAY AFFECT HEPATOBILIARY DISORDERS OR INTERACT WITH THERAPEUTICS

Natural Products
- Alkanet
- Alpine ragwort
- Coltsfoot
- Comfrey
- Dusty miller
- Forget-me-not
Germander
Groundsel
Olive leaf
Parsley oil (large doses)
Pennyroyal
Peppermint
Ragwort
Red yeast rice
Sweet clover
White oak
White willow

**Nutraceuticals**
Creatine

**Amino Acids**
Arginine

**NATURAL PRODUCTS THAT MAY AFFECT IMMUNE DISORDERS OR INTERACT WITH THERAPEUTICS**
Echinacea
Saw palmetto

**NATURAL PRODUCTS THAT MAY AFFECT RESPIRATORY DISORDERS OR INTERACT WITH THERAPEUTICS**
Artichoke
Cayenne
Chamomile
Cordyceps
Echinacea
Feverfew
Garlic
Peppermint oil
White willow

**Natural Products**
Astragalus
Black cohosh
RATIONALE FOR ISOLATION PRECAUTIONS IN HOSPITALS
Transmission of infection within a hospital requires three elements: a source of infecting microorganisms, a susceptible host, and a means of transmission for the microorganism.

Source
Human sources of the infecting microorganisms in hospitals may be patients, personnel, or, on occasion, visitors, and may include persons with acute disease, persons in the incubation period of a disease, persons who are colonized by an infectious agent but have no apparent disease, or persons who are chronic carriers of an infectious agent. Other sources of infecting microorganisms can be the patient’s own endogenous flora, which may be difficult to control, and inanimate environmental objects that have become contaminated, including equipment and medications.

Host
Resistance among persons to pathogenic microorganisms varies greatly. Some persons may be immune to infection or may be able to resist colonization by an infectious agent; others exposed to the same agent may establish a commensal relationship with the infecting microorganism and become asymptomatic carriers; still others may develop clinical disease. Host factors such as age; underlying diseases; certain treatments with antimicrobials, corticosteroids, or other immunosuppressive agents; irradiation; and breaks in the first line of defense mechanisms caused by such factors as surgical operations, anesthesia, and indwelling catheters may render patients more susceptible to infection.

Transmission
Microorganisms are transmitted in hospitals by several routes, and the same microorganism may be transmitted by more than one route. There are five main routes of transmission: contact, droplet, airborne, common vehicle, and vectorborne. For the purpose of this guideline, common vehicle and vectorborne transmission will be discussed only briefly, because neither play a significant role in typical nosocomial infections.

1. Contact transmission, the most important and frequent mode of transmission of nosocomial infections, is divided into two subgroups: direct-contact transmission and indirect-contact transmission.
2. Direct-contact transmission involves a direct body surface-to-body surface contact and physical transfer of microorganisms between a susceptible host and an infected or colonized person, such as occurs when a person turns a patient, gives a patient a bath, or performs other patient-care activities that require direct personal contact. Direct-contact transmission also can occur between two patients, with one serving as the source of the infectious microorganisms and the other as a susceptible host.
3. Indirect-contact transmission involves contact of a susceptible host with a contaminated intermediate object, usually inanimate, such as contaminated
instruments, needles, or dressings, or contaminated hands that are not washed and gloves that are not changed between patients.

4. *Droplet transmission*, theoretically, is a form of contact transmission. However, the mechanism of transfer of the pathogen to the host is quite distinct from either direct- or indirect-contact transmission. Therefore, droplet transmission will be considered a separate route of transmission in this guideline. Droplets are generated from the source person primarily during coughing, sneezing, and talking, and during the performance of certain procedures such as suctioning and bronchoscopy. Transmission occurs when droplets containing microorganisms generated from the infected person are propelled a short distance through the air and deposited on the host’s conjunctivae, nasal mucosa, or mouth. Because droplets do not remain suspended in the air, special air handling and ventilation are not required to prevent droplet transmission; that is, droplet transmission *must not* be confused with airborne transmission.

5. *Airborne transmission* occurs by dissemination of either airborne droplet nuclei (small-particle residue [5 µm or smaller in size] of evaporated droplets containing microorganisms that remain suspended in the air for long periods of time) or dust particles containing the infectious agent. Microorganisms carried in this manner can be dispersed widely by air currents and may become inhaled by a susceptible host within the same room or over a longer distance from the source patient, depending on environmental factors; therefore, special air handling and ventilation are required to prevent airborne transmission. Microorganisms transmitted by airborne transmission include *Mycobacterium tuberculosis* and the rubeola and varicella viruses.

6. *Common vehicle transmission* applies to microorganisms transmitted by contaminated items such as food, water, medications, devices, and equipment.

7. *Vectorborne transmission* occurs when vectors such as mosquitoes, flies, rats, and other vermin transmit microorganisms; this route of transmission is of less significance in hospitals in the United States than in other regions of the world.

Isolation precautions are designed to prevent transmission of microorganisms by these routes in hospitals. Because agent and host factors are more difficult to control, interruption of transfer of microorganisms is directed primarily at transmission. The recommendations presented in this guideline are based on this concept.

Placing a patient on isolation precautions, however, often presents certain disadvantages to the hospital, patients, personnel, and visitors. Isolation precautions may require specialized equipment and environmental modifications that add to the cost of hospitalization. Isolation precautions may make frequent visits by nurses, physicians, and other personnel inconvenient, and they may make it more difficult for personnel to give the prompt and frequent care that sometimes is required. The use of a multi-patient room for one patient uses valuable space that otherwise might accommodate several patients. Moreover, forced solitude deprives the patient of normal social relationships and may be psychologically harmful, especially to children. These disadvantages, however, must be weighed against the hospital’s mission to prevent the spread of serious and epidemiologically important microorganisms in the hospital.
FUNDAMENTALS OF ISOLATION PRECAUTIONS

A variety of infection control measures are used for decreasing the risk of transmission of microorganisms in hospitals. These measures make up the fundamentals of isolation precautions.

Handwashing and Gloving

Handwashing frequently is called the single most important measure to reduce the risks of transmitting organisms from one person to another or from one site to another on the same patient. The scientific rationale, indications, methods, and products for handwashing are delineated in other publications.

Washing hands as promptly and thoroughly as possible between patient contacts and after contact with blood, body fluids, secretions, excretions, and equipment or articles contaminated by them is an important component of infection control and isolation precautions. In addition to handwashing, gloves play an important role in reducing the risks of transmission of microorganisms.

Gloves are worn for three important reasons in hospitals. First, gloves are worn to provide a protective barrier and to prevent gross contamination of the hands when touching blood, body fluids, secretions, excretions, mucous membranes, and nonintact skin; the wearing of gloves in specified circumstances to reduce the risk of exposures to bloodborne pathogens is mandated by the OSHA bloodborne pathogens final rule. Second, gloves are worn to reduce the likelihood that microorganisms present on the hands of personnel will be transmitted to patients during invasive or other patient-care procedures that involve touching a patient’s mucous membranes and nonintact skin. Third, gloves are worn to reduce the likelihood that hands of personnel contaminated with microorganisms from a patient or a fomite can transmit these microorganisms to another patient. In this situation, gloves must be changed between patient contacts and hands washed after gloves are removed.

Wearing gloves does not replace the need for handwashing, because gloves may have small, inapparent defects or may be torn during use, and hands can become contaminated during removal of gloves. Failure to change gloves between patient contacts is an infection control hazard.

Patient Placement

Appropriate patient placement is a significant component of isolation precautions. A private room is important to prevent direct- or indirect-contact transmission when the source patient has poor hygienic habits, contaminates the environment, or cannot be expected to assist in maintaining infection control precautions to limit transmission of microorganisms (e.g., infants, children, and patients with altered mental status). When possible, a patient with highly transmissible or epidemiologically important microorganisms is placed in a private room with handwashing and toilet facilities to reduce opportunities for transmission of microorganisms.

When a private room is not available, an infected patient is placed with an appropriate roommate. Patients infected by the same microorganism usually can share a room, provided they are not infected with other potentially transmissible microorganisms and the likelihood of reinfection with the same organism is minimal. Such sharing of rooms, also referred to as cohorting patients, is useful especially during outbreaks or when there is a shortage of private rooms. When a private room is not available and cohorting is not achievable or recommended, it is very important to consider the epidemiology and mode of transmission of the infecting pathogen and the patient population being served...
in determining patient placement. Under these circumstances, consultation with infection control professionals is advised before patient placement. Moreover, when an infected patient shares a room with a noninfected patient, it also is important that patients, personnel, and visitors take precautions to prevent the spread of infection and that roommates are selected carefully.

Guidelines for construction, equipment, air handling, and ventilation for isolation rooms are delineated in other publications. A private room with appropriate air handling and ventilation is particularly important for reducing the risk of transmission of microorganisms from a source patient to susceptible patients and other persons in hospitals when the microorganism is spread by airborne transmission. Some hospitals use an isolation room with an anteroom as an extra measure of precaution to prevent airborne transmission. Adequate data regarding the need for an anteroom, however, is not available. Ventilation recommendations for isolation rooms housing patients with pulmonary tuberculosis have been delineated in other CDC guidelines.

Transport of Infected Patients

Limiting the movement and transport of patients infected with virulent or epidemiologically important microorganisms and ensuring that such patients leave their rooms only for essential purposes reduces opportunities for transmission of microorganisms in hospitals. When patient transport is necessary, it is important that 1) appropriate barriers (e.g., masks, impervious dressings) are worn or used by the patient to reduce the opportunity for transmission of pertinent microorganisms to other patients, personnel, and visitors and to reduce contamination of the environment; 2) personnel in the area to which the patient is to be taken are notified of the impending arrival of the patient and of the precautions to be used to reduce the risk of transmission of infectious microorganisms; and 3) patients are informed of ways by which they can assist in preventing the transmission of their infectious microorganisms to others.

Masks, Respiratory Protection, Eye Protection, Face Shields

Various types of masks, goggles, and face shields are worn alone or in combination to provide barrier protection. A mask that covers both the nose and the mouth, and goggles or a face shield are worn by hospital personnel during procedures and patient-care activities that are likely to generate splashes or sprays of blood, body fluids, secretions, or excretions to provide protection of the mucous membranes of the eyes, nose, and mouth from contact transmission of pathogens. The wearing of masks, eye protection, and face shields in specified circumstances to reduce the risk of exposures to bloodborne pathogens is mandated by the OSHA bloodborne pathogens final rule. A surgical mask generally is worn by hospital personnel to provide protection against spread of infectious large-particle droplets that are transmitted by close contact and generally travel only short distances (up to 3 ft) from infected patients who are coughing or sneezing.

An area of major concern and controversy over the last several years has been the role and selection of respiratory protection equipment and the implications of a respiratory protection program for prevention of transmission of tuberculosis in hospitals. Traditionally, although the efficacy was not proven, a surgical mask was worn for isolation precautions in hospitals when patients were known or suspected to be infected with pathogens spread by the airborne route of transmission. In 1990, however, the CDC tuberculosis
guidelines stated that surgical masks may not be effective in preventing the inhalation of droplet nuclei and recommended the use of disposable particulate respirators, despite the fact that the efficacy of particulate respirators in protecting persons from the inhalation of *M. tuberculosis* had not been demonstrated. By definition, particulate respirators included dust-mist (DM), dust-fume-mist (DFM), or high-efficiency particulate air (HEPA) filter respirators certified by the CDC National Institute for Occupational Safety and Health (NIOSH); because the generic term “particulate respirator” was used in the 1990 guidelines, the implication was that any of these respirators provided sufficient protection.

In 1993, a draft revision of the CDC tuberculosis guidelines outlined performance criteria for respirators and stated that some DM or DFM respirators might not meet these criteria. After review of public comments, the guidelines were finalized in October 1994, with the draft respirator criteria unchanged. At that time, the only class of respirators that were known to consistently meet or exceed the performance criteria outlined in the 1994 tuberculosis guidelines and that were certified by NIOSH (as required by OSHA) were HEPA filter respirators. Subsequently, NIOSH revised the testing and certification requirements for all types of air-purifying respirators, including those used for tuberculosis control. The new rule, effective in July 1995, provides a broader range of certified respirators that meet the performance criteria recommended by CDC in the 1994 tuberculosis guidelines. NIOSH has indicated that the N95 (N category at 95% efficiency) meets the CDC performance criteria for a tuberculosis respirator. The new respirators are likely to be available in late 1995. Additional information on the evolution of respirator recommendations, regulations to protect hospital personnel, and the role of various federal agencies in respiratory protection for hospital personnel has been published.

**Gowns and Protective Apparel**

Various types of gowns and protective apparel are worn to provide barrier protection and to reduce opportunities for transmission of microorganisms in hospitals. Gowns are worn to prevent contamination of clothing and to protect the skin of personnel from blood and body fluid exposures. Gowns especially treated to make them impermeable to liquids, leg coverings, boots, or shoe covers provide greater protection to the skin when splashes or large quantities of infective material are present or anticipated. The wearing of gowns and protective apparel under specified circumstances to reduce the risk of exposures to bloodborne pathogens is mandated by the OSHA bloodborne pathogens final rule.

Gowns are also worn by personnel during the care of patients infected with epidemiologically important microorganisms to reduce the opportunity for transmission of pathogens from patients or items in their environment to other patients or environments; when gowns are worn for this purpose, they are removed before leaving the patient’s environment and hands are washed. Adequate data regarding the efficacy of gowns for this purpose, however, are not available.

**Patient-Care Equipment and Articles**

Many factors determine whether special handling and disposal of used patient-care equipment and articles are prudent or required, including the likelihood of contamination with infective material; the ability to cut, stick, or
otherwise cause injury (needles, scalpels, and other sharp instruments [sharps]); the severity of the associated disease; and the environmental stability of the pathogens involved. Some used articles are enclosed in containers or bags to prevent inadvertent exposures to patients, personnel, and visitors and to prevent contamination of the environment. Used sharps are placed in puncture-resistant containers; other articles are placed in a bag. One bag is adequate if the bag is sturdy and the article can be placed in the bag without contaminating the outside of the bag; otherwise, two bags are used.

The scientific rationale, indications, methods, products, and equipment for reprocessing patient-care equipment are delineated in other publications. Contaminated, reusable critical medical devices or patient-care equipment (i.e., equipment that enters normally sterile tissue or through which blood flows) or semicritical medical devices or patient-care equipment (i.e., equipment that touches mucous membranes) are sterilized or disinfected (reprocessed) after use to reduce the risk of transmission of microorganisms to other patients; the type of reprocessing is determined by the article and its intended use, the manufacturer’s recommendations, hospital policy, and any applicable guidelines and regulations.

Noncritical equipment (i.e., equipment that touches intact skin) contaminated with blood, body fluids, secretions, or excretions is cleaned and disinfected after use, according to hospital policy. Contaminated disposable (single-use) patient-care equipment is handled and transported in a manner that reduces the risk of transmission of microorganisms and decreases environmental contamination in the hospital; the equipment is disposed of according to hospital policy and applicable regulations.

**Linen and Laundry**

Although soiled linen may be contaminated with pathogenic microorganisms, the risk of disease transmission is negligible if it is handled, transported, and laundered in a manner that avoids transfer of microorganisms to patients, personnel, and environments. Rather than rigid rules and regulations, hygienic and common sense storage and processing of clean and soiled linen are recommended. The methods for handling, transporting, and laundering of soiled linen are determined by hospital policy and any applicable regulations.

**Dishes, Glasses, Cups, and Eating Utensils**

No special precautions are needed for dishes, glasses, cups, or eating utensils. Either disposable or reusable dishes and utensils can be used for patients on isolation precautions. The combination of hot water and detergents used in hospital dishwashers is sufficient to decontaminate dishes, glasses, cups, and eating utensils.

**Routine and Terminal Cleaning**

The room, or cubicle, and bedside equipment of patients on Transmission-Based Precautions are cleaned using the same procedures used for patients on Standard Precautions, unless the infecting microorganism(s) and the amount of environmental contamination indicates special cleaning. In addition to thorough cleaning, adequate disinfection of bedside equipment and environmental surfaces (e.g., bedrails, bedside tables, carts, commodes, doorknobs, faucet handles) is indicated for certain pathogens, especially enterococci, which can survive in the inanimate environment for prolonged periods of time. Patients admitted to hospital rooms that previously were occupied by patients infected
or colonized with such pathogens are at increased risk of infection from contaminated environmental surfaces and bedside equipment if they have not been cleaned and disinfected adequately. The methods, thoroughness, and frequency of cleaning and the products used are determined by hospital policy.

HICPAC ISOLATION PRECAUTIONS

There are two tiers of HICPAC isolation precautions. In the first, and most important, tier are those precautions designed for the care of all patients in hospitals, regardless of their diagnosis or presumed infection status. Implementation of these “Standard Precautions” is the primary strategy for successful nosocomial infection control. In the second tier are precautions designed only for the care of specified patients. These additional “Transmission-Based Precautions” are for patients known or suspected to be infected by epidemiologically important pathogens spread by airborne or droplet transmission or by contact with dry skin or contaminated surfaces.

Standard Precautions

Standard Precautions synthesize the major features of UP (Blood and Body Fluid Precautions) (designed to reduce the risk of transmission of bloodborne pathogens) and BSI (designed to reduce the risk of transmission of pathogens from moist body substances) and applies them to all patients receiving care in hospitals, regardless of their diagnosis or presumed infection status. Standard Precautions apply to 1) blood; 2) all body fluids, secretions, and excretions except sweat, regardless of whether or not they contain visible blood; 3) nonintact skin; and 4) mucous membranes. Standard Precautions are designed to reduce the risk of transmission of microorganisms from both recognized and unrecognized sources of infection in hospitals.

Transmission-Based Precautions

Transmission-Based Precautions are designed for patients documented or suspected to be infected with highly transmissible or epidemiologically important pathogens for which additional precautions beyond Standard Precautions are needed to interrupt transmission in hospitals. There are three types of Transmission-Based Precautions: Airborne Precautions, Droplet Precautions, and Contact Precautions. They may be combined for diseases that have multiple routes of transmission. When used either singularly or in combination, they are to be used in addition to Standard Precautions.

Airborne Precautions are designed to reduce the risk of airborne transmission of infectious agents. Airborne transmission occurs by dissemination of either airborne droplet nuclei (small-particle residue [5 µm or smaller in size] of evaporated droplets that may remain suspended in the air for long periods of time) or dust particles containing the infectious agent. Microorganisms carried in this manner can be dispersed widely by air currents and may become inhaled by or deposited on a susceptible host within the same room or over a longer distance from the source patient, depending on environmental factors; therefore, special air handling and ventilation are required to prevent airborne transmission. Airborne Precautions apply to patients known or suspected to be infected with epidemiologically important pathogens that can be transmitted by the airborne route.

Droplet Precautions are designed to reduce the risk of droplet transmission of infectious agents. Droplet transmission involves contact of the conjunctivae or the mucous membranes of the nose or mouth of a susceptible
person with large-particle droplets (larger than 5 µm in size) containing microorganisms generated from a person who has a clinical disease or who is a carrier of the microorganism. Droplets are generated from the source person primarily during coughing, sneezing, or talking and during the performance of certain procedures such as suctioning and bronchoscopy. Transmission via large-particle droplets requires close contact between source and recipient persons, because droplets do not remain suspended in the air and generally travel only short distances, usually 3 ft or less, through the air. Because droplets do not remain suspended in the air, special air handling and ventilation are not required to prevent droplet transmission. Droplet Precautions apply to any patient known or suspected to be infected with epidemiologically important pathogens that can be transmitted by infectious droplets.

Contact Precautions are designed to reduce the risk of transmission of epidemiologically important microorganisms by direct or indirect contact. Direct-contact transmission involves skin-to-skin contact and physical transfer of microorganisms to a susceptible host from an infected or colonized person, such as occurs when personnel turn patients, bathe patients, or perform other patient-care activities that require physical contact. Direct-contact transmission also can occur between two patients (e.g., by hand contact), with one serving as the source of infectious microorganisms and the other as a susceptible host. Indirect-contact transmission involves contact of a susceptible host with a contaminated intermediate object, usually inanimate, in the patient’s environment. Contact Precautions apply to specified patients known or suspected to be infected or colonized (presence of microorganism in or on patient but without clinical signs and symptoms of infection) with epidemiologically important microorganisms that can be transmitted by direct or indirect contact.

EMPIRIC USE OF AIRBORNE, DROPLET, OR CONTACT PRECAUTIONS
In many instances, the risk of nosocomial transmission of infection may be highest before a definitive diagnosis can be made and before precautions based on that diagnosis can be implemented. The routine use of Standard Precautions for all patients should reduce greatly this risk for conditions other than those requiring Airborne, Droplet, or Contact Precautions. While it is not possible to prospectively identify all patients needing these enhanced precautions, certain clinical syndromes and conditions carry a sufficiently high risk to warrant the empiric addition of enhanced precautions while a more definitive diagnosis is pursued.

The organisms listed under the column “Potential Pathogens” are not intended to represent the complete or even most likely diagnoses, but rather possible etiologic agents that require additional precautions beyond Standard Precautions until they can be ruled out. Infection control professionals are encouraged to modify or adapt this table according to local conditions. To ensure that appropriate empiric precautions are implemented always, hospitals must have systems in place to evaluate patients routinely, according to these criteria as part of their preadmission and admission care.

IMMUNOCOMPROMISED PATIENTS
Immunocompromised patients vary in their susceptibility to nosocomial infections, depending on the severity and duration of immunosuppression. They generally are at increased risk for bacterial, fungal, parasitic, and viral infections from both endogenous and exogenous sources. The use of Standard Precautions for all patients and Transmission-Based Precautions for specified
patients, as recommended in this guideline, should reduce the acquisition by these patients of institutionally acquired bacteria from other patients and environments.

It is beyond the scope of this guideline to address the various measures that may be used for immunocompromised patients to delay or prevent acquisition of potential pathogens during temporary periods of neutropenia. Rather, the primary objective of this guideline is to prevent transmission of pathogens from infected or colonized patients in hospitals. Users of this guideline, however, are referred to the “Guideline for Prevention of Nosocomial Pneumonia” (95,96) for the HICPAC recommendations for prevention of nosocomial aspergillosis and Legionnaires’ disease in immunocompromised patients.

RECOMMENDATIONS

The recommendations presented below are categorized as follows:

**Category IA.** Strongly recommended for all hospitals and strongly supported by well-designed experimental or epidemiologic studies.

**Category IB.** Strongly recommended for all hospitals and reviewed as effective by experts in the field and a consensus of HICPAC based on strong rationale and suggestive evidence, even though definitive scientific studies have not been done.

**Category II.** Suggested for implementation in many hospitals. Recommendations may be supported by suggestive clinical or epidemiologic studies, a strong theoretical rationale, or definitive studies applicable to some, but not all, hospitals.

**No recommendation; unresolved issue.** Practices for which insufficient evidence or consensus regarding efficacy exists.

The recommendations are limited to the topic of isolation precautions. Therefore, they must be supplemented by hospital policies and procedures for other aspects of infection and environmental control, occupational health, administrative and legal issues, and other issues beyond the scope of this guideline.

1. **Administrative Controls**
   a. **Education**
      Develop a system to ensure that hospital patients, personnel, and visitors are educated about use of precautions and their responsibility for adherence to them. Category IB
   b. **Adherence to Precautions**
      Periodically evaluate adherence to precautions, and use findings to direct improvements. Category IB

2. **Standard Precautions**
   Use Standard Precautions, or the equivalent, for the care of all patients. Category IB
   a. **Handwashing**
      1. Wash hands after touching blood, body fluids, secretions, excretions, and contaminated items, whether or not gloves are worn. Wash hands immediately after gloves are removed, between patient contacts, and when otherwise indicated to avoid transfer of microorganisms to other patients or environments. It may be necessary to wash hands between tasks and procedures on the same patient to prevent cross-contamination of different body sites. Category IB
(2) Use a plain (nonantimicrobial) soap for routine handwashing. Category IB

(3) Use an antimicrobial agent or a waterless antiseptic agent for specific circumstances (e.g., control of outbreaks or hyperendemic infections), as defined by the infection control program. Category IB (See Contact Precautions for additional recommendations on using antimicrobial and antiseptic agents.)

b. Gloves
Wear gloves (clean, nonsterile gloves are adequate) when touching blood, body fluids, secretions, excretions, and contaminated items. Put on clean gloves just before touching mucous membranes and nonintact skin. Change gloves between tasks and procedures on the same patient after contact with material that may contain a high concentration of microorganisms. Remove gloves promptly after use, before touching noncontaminated items and environmental surfaces, and before going to another patient, and wash hands immediately to avoid transfer of microorganisms to other patients or environments. Category IB

c. Mask, Eye Protection, Face Shield
Wear a mask and eye protection or a face shield to protect mucous membranes of the eyes, nose, and mouth during procedures and patient-care activities that are likely to generate splashes or sprays of blood, body fluids, secretions, and excretions. Category IB

d. Gown
Wear a gown (a clean, nonsterile gown is adequate) to protect skin and to prevent soiling of clothing during procedures and patient-care activities that are likely to generate splashes or sprays of blood, body fluids, secretions, or excretions. Select a gown that is appropriate for the activity and amount of fluid likely to be encountered. Remove a soiled gown as promptly as possible, and wash hands to avoid transfer of microorganisms to other patients or environments. Category IB

e. Patient-Care Equipment
Handle used patient-care equipment soiled with blood, body fluids, secretions, and excretions in a manner that prevents skin and mucous membrane exposures, contamination of clothing, and transfer of microorganisms to other patients and environments. Ensure that reusable equipment is not used for the care of another patient until it has been cleaned and reprocessed appropriately. Ensure that single-use items are discarded properly. Category IB

f. Environmental Control
Ensure that the hospital has adequate procedures for the routine care, cleaning, and disinfection of environmental surfaces, beds, bedrails, bedside equipment, and other frequently touched surfaces, and ensure that these procedures are being followed. Category IB

g. Linen
Handle, transport, and process used linen soiled with blood, body fluids, secretions, and excretions in a manner that prevents skin and mucous membrane exposures and contamination of clothing, and that avoids transfer of microorganisms to other patients and environments. Category IB

h. Occupational Health and Bloodborne Pathogens
(1) Take care to prevent injuries when using needles, scalpels, and other sharp instruments or devices; when handling sharp instruments after
procedures; when cleaning used instruments; and when disposing of used needles. Never recap used needles, or otherwise manipulate them using both hands, or use any other technique that involves directing the point of a needle toward any part of the body; rather, use either a one-handed “scoop” technique or a mechanical device designed for holding the needle sheath. Do not remove used needles from disposable syringes by hand, and do not bend, break, or otherwise manipulate used needles by hand. Place used disposable syringes and needles, scalpel blades, and other sharp items in appropriate puncture-resistant containers, which are located as close as practical to the area in which the items were used, and place reusable syringes and needles in a puncture-resistant container for transport to the reprocessing area. Category IB(2) Use mouthpieces, resuscitation bags, or other ventilation devices as an alternative to mouth-to-mouth resuscitation methods in areas where the need for resuscitation is predictable. Category IB

i. Patient Placement
Place a patient who contaminates the environment or who does not (or cannot be expected to) assist in maintaining appropriate hygiene or environmental control in a private room. If a private room is not available, consult with infection control professionals regarding patient placement or other alternatives. Category IB

3. Airborne Precautions
In addition to Standard Precautions, use Airborne Precautions, or the equivalent, for patients known or suspected to be infected with microorganisms transmitted by airborne droplet nuclei (small-particle residue [5 µm or smaller in size] of evaporated droplets containing microorganisms that remain suspended in the air and that can be dispersed widely by air currents within a room or over a long distance). Category IB

a. Patient Placement
Place the patient in a private room that has 1) monitored negative air pressure in relation to the surrounding areas, 2) 6 to 12 air changes per hour, and 3) appropriate discharge of air outdoors or monitored high-efficiency filtration of room air before the air is circulated to other areas in the hospital. Keep the room door closed and the patient in the room. When a private room is not available, place the patient in a room with a patient who has active infection with the same microorganism, unless otherwise recommended, but with no other infection. When a private room is not available and cohorting is not desirable, consultation with infection control professionals is advised before patient placement. Category IB

b. Respiratory Protection
Wear respiratory protection (N95 respirator) when entering the room of a patient with known or suspected infectious pulmonary tuberculosis. Susceptible persons should not enter the room of patients known or suspected to have measles (rubeola) or varicella (chickenpox) if other immune caregivers are available. If susceptible persons must enter the room of a patient known or suspected to have measles (rubeola) or varicella, they should wear respiratory protection (N95 respirator). Persons immune to measles (rubeola) or varicella need not wear respiratory protection. Category IB
c. Patient Transport
   Limit the movement and transport of the patient from the room to essential purposes only. If transport or movement is necessary, minimize patient dispersal of droplet nuclei by placing a surgical mask on the patient, if possible. Category IB
d. Additional Precautions for Preventing Transmission of Tuberculosis:
   Consult CDC “Guidelines for Preventing the Transmission of Tuberculosis in Health-Care Facilities” for additional prevention strategies.

4. Droplet Precautions
   In addition to Standard Precautions, use Droplet Precautions, or the equivalent, for a patient known or suspected to be infected with microorganisms transmitted by droplets (large-particle droplets [larger than 5 µm in size] that can be generated by the patient during coughing, sneezing, talking, or the performance of procedures). Category IB
   a. Patient Placement
      Place the patient in a private room. When a private room is not available, place the patient in a room with a patient(s) who has active infection with the same microorganism but with no other infection (cohorting). When a private room is not available and cohorting is not achievable, maintain spatial separation of at least 3 ft between the infected patient and other patients and visitors. Special air handling and ventilation are not necessary, and the door may remain open. Category IB
   b. Mask
      In addition to wearing a mask as outlined under Standard Precautions, wear a mask when working within 3 ft of the patient. (Logistically, some hospitals may want to implement the wearing of a mask to enter the room.) Category IB
c. Patient Transport
   Limit the movement and transport of the patient from the room to essential purposes only. If transport or movement is necessary, minimize patient dispersal of droplets by masking the patient, if possible. Category IB

5. Contact Precautions
   In addition to Standard Precautions, use Contact Precautions, or the equivalent, for specified patients known or suspected to be infected or colonized with epidemiologically important microorganisms that can be transmitted by direct contact with the patient (hand or skin-to-skin contact that occurs when performing patient-care activities that require touching the patient’s dry skin) or indirect contact (touching) with environmental surfaces or patient-care items in the patient’s environment. Category IB
   a. Patient Placement
      Place the patient in a private room. When a private room is not available, place the patient in a room with a patient(s) who has active infection with the same microorganism but with no other infection (cohorting). When a private room is not available and cohorting is not achievable, consider the epidemiology of the microorganism and the patient population when determining patient placement. Consultation with infection control professionals is advised before patient placement. Category IB
   b. Gloves and Handwashing
      In addition to wearing gloves as outlined under Standard Precautions, wear gloves (clean, nonsterile gloves are adequate) when entering the room. During the course of providing care for a patient, change
gloves after having contact with infective material that may contain high concentrations of microorganisms (fecal material and wound drainage). Remove gloves before leaving the patient’s room and wash hands immediately with an antimicrobial agent or a waterless antiseptic agent. After glove removal and handwashing, ensure that hands do not touch potentially contaminated environmental surfaces or items in the patient’s room to avoid transfer of microorganisms to other patients or environments. Category IB

c. Gown
In addition to wearing a gown as outlined under Standard Precautions, wear a gown (a clean, nonsterile gown is adequate) when entering the room if you anticipate that your clothing will have substantial contact with the patient, environmental surfaces, or items in the patient’s room, or if the patient is incontinent or has diarrhea, an ileostomy, a colostomy, or wound drainage not contained by a dressing. Remove the gown before leaving the patient’s environment. After gown removal, ensure that clothing does not contact potentially contaminated environmental surfaces to avoid transfer of microorganisms to other patients or environments. Category IB

d. Patient Transport
Limit the movement and transport of the patient from the room to essential purposes only. If the patient is transported out of the room, ensure that precautions are maintained to minimize the risk of transmission of microorganisms to other patients and contamination of environmental surfaces or equipment. Category IB

e. Patient-Care Equipment
When possible, dedicate the use of noncritical patient-care equipment to a single patient (or cohort of patients infected or colonized with the pathogen requiring precautions) to avoid sharing between patients. If use of common equipment or items is unavoidable, then adequately clean and disinfect them before use for another patient. Category IB

f. Additional Precautions for Preventing the Spread of Vancomycin Resistance
Consult the HICPAC report on preventing the spread of vancomycin resistance for additional prevention strategies.

Revision to OSHA’s Bloodborne Pathogens Standard

TECHNICAL BACKGROUND AND SUMMARY
April 2001

Background
The Occupational Safety and Health Administration published the Occupational Exposure to Bloodborne Pathogens standard in 1991 because of a significant health risk associated with exposure to viruses and other microorganisms that cause bloodborne diseases. Of primary concern are the human immunodeficiency virus (HIV) and the hepatitis B and hepatitis C viruses.

The standard sets forth requirements for employers with workers exposed to blood or other potentially infectious materials. In order to reduce or eliminate the hazards of occupational exposure, an employer must implement an exposure control plan for the worksite with details on employee protection measures. The plan must also describe how an employer will use a combination of engineering and work practice controls, ensure the use of personal protective clothing and equipment, provide training, medical surveillance, hepatitis B vaccinations, and signs and labels, among other provisions. Engineering controls are the primary means of eliminating or minimizing employee exposure and include the use of safer medical devices, such as needleless devices, shielded needle devices, and plastic capillary tubes.

Nearly 10 years have passed since the bloodborne pathogens standard was published. Since then, many different medical devices have been developed to reduce the risk of needlesticks and other sharps injuries. These devices replace sharps with non-needle devices or incorporate safety features designed to reduce injury. Despite these advances in technology, needlesticks and other sharps injuries continue to be of concern due to the high frequency of their occurrence and the severity of the health effects.

The Centers for Disease Control and Prevention estimate that healthcare workers sustain nearly 600,000 percutaneous injuries annually involving contaminated sharps. In response to both the continued concern over such exposures and the technological developments which can increase employee protection, Congress passed the Needlestick Safety and Prevention Act directing OSHA to revise the bloodborne pathogens standard to establish in greater detail requirements that employers identify and make use of effective and safer medical devices. That revision was published on Jan. 18, 2001, and became effective April 18, 2001.

SUMMARY
The revision to OSHA’s bloodborne pathogens standard added new requirements for employers, including additions to the exposure control plan and keeping a sharps injury log. It does not impose new requirements for employers to protect workers from sharps injuries; the original standard already required employers to adopt engineering and work practice controls that would eliminate or minimize employee exposure from hazards associated with bloodborne pathogens.

The revision does, however, specify in greater detail the engineering controls, such as safer medical devices, which must be used to reduce or eliminate worker exposure.

EXPOSURE CONTROL PLAN
The revision includes new requirements regarding the employer’s Exposure Control Plan, including an annual review and update to reflect changes in technology that eliminate or reduce exposure to bloodborne pathogens. The employer must:

- take into account innovations in medical procedure and technological developments that reduce the risk of exposure (e.g., newly available medical devices designed to reduce needlesticks); and
- document consideration and use of appropriate, commercially available, and effective safer devices (e.g., describe the devices identified as candidates for use, the method(s) used to evaluate those devices, and justification for the eventual selection).
No one medical device is considered appropriate or effective for all circumstances. Employers must select devices that, based on reasonable judgment:

- will not jeopardize patient or employee safety or be medically inadvisable; and
- will make an exposure incident involving a contaminated sharp less likely to occur.

**EMPLOYEE INPUT**

Employers must solicit input from non-managerial employees responsible for direct patient care regarding the identification, evaluation, and selection of effective engineering controls, including safer medical devices. Employees selected should represent the range of exposure situations encountered in the workplace, such as those in geriatric, pediatric, or nuclear medicine, and others involved in direct care of patients.

OSHA will check for compliance with this provision during inspections by questioning a representative number of employees to determine if and how their input was requested.

**Documentation of Employee Input**

Employers are required to document, in the Exposure Control Plan, how they received input from employees. This obligation can be met by:

- Listing the employees involved and describing the process by which input was requested; or
- Presenting other documentation, including references to the minutes of meetings, copies of documents used to request employee participation, or records of responses received from employees.

**RECORDKEEPING**

Employers who have employees who are occupationally exposed to blood or other potentially infectious materials, and who are required to maintain a log of occupational injuries and illnesses under existing recordkeeping rules, must also maintain a sharps injury log. That log will be maintained in a manner that protects the privacy of employees. At a minimum, the log will contain the following:

- the type and brand of device involved in the incident;
- location of the incident (e.g., department or work area); and
- description of the incident.

The sharps injury log may include additional information as long as an employee's privacy is protected. The format of the log can be determined by the employer.

**MODIFICATION OF DEFINITIONS**

The revision to the bloodborne pathogens standard includes modification of definitions relating to engineering controls. Two terms have been added to the standard, while the description of an existing term has been amended.

**Engineering Controls**

Engineering Controls include all control measures that isolate or remove a hazard from the workplace, such as sharps disposal containers and self-sheathing needles. The original bloodborne pathogens standard was not
specific regarding the applicability of various engineering controls (other than the above examples) in the healthcare setting. The revision now specifies that “safer medical devices, such as sharps with engineered sharps injury protections and needleless systems” constitute an effective engineering control, and must be used where feasible.

**Sharps with Engineered Sharps Injury Protections**

This is a new term which includes non-needle sharps or needle devices containing built-in safety features that are used for collecting fluids or administering medications or other fluids, or other procedures involving the risk of sharps injury. This description covers a broad array of devices, including:

- syringes with a sliding sheath that shields the attached needle after use;
- needles that retract into a syringe after use;
- shielded or retracting catheters; and
- intravenous medication (IV) delivery systems that use a catheter port with a needle housed in a protective covering.

**Needleless Systems**

This is a new term defined as devices which provide an alternative to needles for various procedures to reduce the risk of injury involving contaminated sharps. Examples include:

- IV medication systems which administer medication or fluids through a catheter port using non-needle connections; and
- jet injection systems which deliver liquid medication beneath the skin or through a muscle.

angiogram/arteriogram of, 57–61
computed tomography of, 403–407
FDG-PET scan of, 598–601
gastrointestinal blood loss scan and, 651–654
KUB study of, 770–772
laparoscopy of, 782–785
liver and spleen scan of, 800–803
lymph node sonography of, 1150–1152
Meckel’s diverticulum scan of, 864–867
MRI of, 832–835
pelvic sonography of, 1155–1158
Abdominal abscess, CT of, 404–407
Abdominal aortic disease, MRI of, 844–846
Abdominal malignancy, 936–938
Abdominal mass, 783
KUB study of, 770–772
laparoscopy of, 782–785
liver and spleen scan of, 800–803
MRI of, 832–835
Abdominal obstruction, CT of, 404–407
Abdominal pain
acetaminophen intoxication and, 54–57
gastrointestinal blood loss scan, 651–654
KUB study of, 770–772
laparoscopy of, 985–988
Meckel’s diverticulum scan for, 865–867
urine porphyrins and, 959–962
Abdominal trauma/injury
amylose levels with, 52–53
CT of, 403–407
laparoscopy of, 782–785
liver/spleen scan after, 800–803
peritoneal fluid analysis for, 936–938
ultrasoundography after, 1155–1158
Abdominal wall defect, fetal, AFP and, 613–617
Abetalipoproteinemia
apoliprotein A and, 141–143
HDLc and LDLc levels in, 326–329
triglyceride levels and, 1108–1111
vitamin A and, 1227
vitamin E and, 1223–1224
ABG (arterial blood gas), 221–232
ABO blood group, 233–237
ABO hemolytic reaction, transfusion related, 1269–1272
Abortion
AFP levels in, 615
human chorionic gonadotropin level in, 715
progesterone testing for, 989–990
ABR (auditory brainstem response), 590
Abrasion
slit-lamp biomicroscopy of, 1061
Abruptio placenta
fibrin degradation product and, 1061
ultrasoundography for, 1136–1139
Abscess, 79–82
abdominal angiography of, 58–61
abdominal CT of, 404–407
brain CT of, 417–420
bronchoscopy for, 250–253
cancer antigen levels in, 284–285
cardio angiography of, 67–69
CT angiography of, 409–412
EEG determining, 563–564
gallium scan for, 636–638
kidney CT for, 442–445
liver and spleen scan for, 801–803
liver/biliary tract CT of, 412–416
mamography for, 862–864
MRI for, 837–839, 859–861
pancreatic CT of, 429–433
pelvic CT of, 433–437
pituitary CT of, 438–441
proctosigmoidoscopy for, 985–988
renogram for, 1040–1042
retrograde ureteropyelography for, 1045–1048
spleenic CT of, 450–453
thoracic CT for, 454–456
ultrasoundography for, 1143, 1150, 1159, 1162, 1164
WBC and differential in, 400–403
white blood cell scan for, 1231–1233
Abscess drainage, breast ultrasoundography for, 1143–1147
Absolute value, 397
Absolute white blood cell count, 362
Absorptiometry, radiographic, 242–245
Abuse. See specific types, e.g., Drug abuse
ACA (anticardiolipin antibody), 113–115
Acute cholecystitis, hepatobiliary scan for, 701–704
Acanthocyte, 363, 392
Accessory spleen, 1164–1166
AcCHS (pseudochoolinesterase), 1011–1012, 1030
ACE (angiotensin-converting enzyme), 82–83, 133–134
Acetaminophen, 54
lactic acid levels and, 777–779
Acetone, 768
Acetylcholine receptor (AChR) antibody, 1–3
Acetylcholinesterase (AChE), 1030
amniotic fluid analysis and, 46
Acetylsalicylic acid, 54–57
Achalasia
barium swallow for, 160–162
capsule endoscopy for, 274–276
esophageal manometry for, 583
upper GI series for, 1172–1174
AChE (acetylcholinesterase), 1030
amniotic fluid analysis and, 46
Acid-base balance
blood gases and, 223–232
carbon dioxide and, 276–279
carbonate and, 306–310
potassium and, 227–232
serum osmolality and, 899–902
sodium and, 1064–1067
Acid-base disturbance, 225–232
Acidosis, 224. See also specific types, e.g.,
Ketoacidosis; Metabolic acidosis
calcium values in, 260–263
carbon dioxide levels in, 277–279
catecholamine levels in, 287–290
carbonate levels in, 308–310
diabetic. See Diabetic acidosis;
Diabetic ketoacidosis	onalyzed calcium values in, 265–267
ketone level in, 767–770. See also
Ketoacidosis
lactic. See Lactic acidosis
metabolic. See Metabolic acidosis
potassium levels and, 975–978
renal tubular. See Renal tubular acidosis
respiratory. See Respiratory acidosis
Aciduria, methylmalonic, ketones and, 767–770
Acoustic neuroma
evoked brain potentials in, 591–594
MRI for, 837–839
Acquired angioedema, C4 complement and, 357–358
Acquired aplastic anemia, 689–691
Acquired hemolytic anemia, osmotic fragility and, 902–903
Acquired immune deficiency syndrome (AIDS), 880–883. See also Human immunodeficiency virus (HIV)
alanine aminotransferase levels in, 13–15
gallium scan for, 636–638
mycobacteria culture/smear for, 488
osmotic fragility and, 902–903
platelet antibody and, 948–949
Pneumocystis jiroveci (carinii) and, 530–534
T-cell enumeration for, 292–293
viral culture for, 517–519
WBC and differential in, 400–403
zinc level in, 1235–1236
Acquired methemoglobinemia, 874
Acquired porphyria, 902–903, 960–962
Acquired pyruvate kinase deficiency, 902–903
Acrodermatitis enteropathica, 1234, 1235–1236
Acromegaly
blood creatinine clearance test and, 477–479
calcium values in, 260–263
glucagon level in, 655–657
glucose levels in, 658–662
human growth hormone levels in, 683–684
insulin levels in, 745–747
phosphorous levels in, 939–942
TBG level in, 1098–1099
urinary calcium levels in, 268–271
urine creatinine clearance test and, 481–484
WBC and differential in, 400–403
ACTH. See Adrenocorticotropic hormone (ACTH)
Actinomyces israelii, 515–516
Actinomyces spp., 917
Activated charcoal
anticonvulsant toxicity and, 261–263
antidepressant drug toxicity and, 124–128
antipsychotic toxicity and, 131–134
digoxin toxicity and, 86–92
haloperidol toxicity and, 131–134
lithium toxicity and, 131–134
methemoglobin toxicity and, 874–876
Activated partial thromboplastin time (aPTT), 811, 925–929
Activity intolerance, Holter monitor and, 707–709
Acute cholecystitis, 797–799
Acute gout, 940–942
Acute hemolysis, 399–403
WBC and differential in, 400–403
Acute hemolytic transfusion reaction, 1269–1270
Acute hepatitis. See Hepatitis
Acute immune-mediated transfusion reaction, 1269–1270
Acute infection
transferrin level in, 1106–1108
zinc level in, 1235–1236
Acute intermittent porphyria, 1097–1099
antidiuretic hormone and, 129–130
blood gas analysis in, 226–232
carbon dioxide levels in, 277–279
total cholesterol level in, 330–333
Acute leukemia
amino acid levels in, urine test for, 40
LAP levels in, 795–797
pyruvate kinase levels in, 1020
Acute myeloblastic leukemia, 174–177
Acute myelogenous leukemia, 4
Acute myeloid leukemia, 948–949
Acute myocardial infarction
erthrocyte sedimentation rate and, 577–578
fibrinogen level in, 620–622
haptoglobin level and, 686–687
troponin level in, 1117–1118
Acute myocardial infarction scan, 750–752
Acute nephritis, 269–271
Acute non-immune-mediated transfusion reaction, 1270–1271
Acute pancreatitis
alanine aminotransferase levels in, 13–15
aldolase levels in, 18–19
calcium values in, 261–263
glucagon level in, 655–657
Acute porphyrias, 41–43. See also Acute intermittent porphyria
Acute poststreptococcal glomerulonephritis, 485–486
Acute renal failure
BUN level in, 1178–1180
carbon dioxide levels in, 278–279
Acute respiratory distress syndrome (ARDS), A/a gradient and a/A ratio in, 30
Acute respiratory failure, 517–519
Acute tubular necrosis
MRI for, 833–835
renogram for, 1040–1042
Acute-phase inflammatory response, prealbumin and, 982–984
Acute-phase reaction
C3 and C4 complement and, 356–358
total complement and, 359–360
Addison’s disease
ACTH levels in, 10
aldosterone levels in, 20–22
blood gas analysis in, 227–232
calcium levels in, 260–263
chloride values in, 308–310, 311–314
cortisol levels in, 465–467
DHEAS and, 542–543
eosinophil count in, 573–575
fetal fat and, 606–608
glucose levels in, 659–662
magnesium level and, 822–824
potassium levels and, 975–978, 980–982
renin value in, 1036–1039
sodium levels in, 1066–1067
WBC and differential in, 400–403
Adenoma
aldosterone levels in, 20–22
cortisol levels in, 465–467
pituitary CT of, 438–441
thyroid scan for, 1090–1092
ultrasonography for, 1148–1149
Adenomyosis, 855–857
Adenopathy, 852–854
Adenosine diphosphate (ADP), 902–903
Adenosine triphosphate (ATP), 902–903
Adenovirus, 517–519
ADH. See Antidiuretic hormone (ADH)
ADHD (attention-deficit hyperactivity disorder), 126–128
Adhesion
hysterosalpingography and, 727–730
laparoscopy and, 782–785, 785–788
ADNase-B (antideoxyribonuclease-B), 122–124
Adnexal torsion, 1136–1139, 1156–1158
Adnexal tumor, 1156–1158
Adolescent
age-specific communication and, 1266–1267
amino acid screen in, 39–41
ADP (adenosine diphosphate), 902–903
Adrenal adenoma
ACTH levels in, 10
adrenal angiography of, 63–65
cortisol levels in, 465–467
kidney CT for, 442–445
Adrenal cancer, 10
Adrenal carcinoma
adrenal angiography of, 63–65
glucose levels in, 659–662
Adrenal cortex, 542
Adrenal failure
sodium levels and, 1068–1071
Adrenal gland
angiography of, 62–65
scintiscan of, 4–7
Adrenal gland disorder, 129–130
Adrenal hyperfunction
cortisol levels in, 464–467
Adrenal hyperplasia
abdominal CT of, 404–407
adrenal angiography of, 63–65
adrenal scan for, 5
kidney CT for, 442–445
testosterone and, 1085–1086
Adrenal hypofunction, 465–467
Adrenal insufficiency, 9–10
DHEAS and, 542–543
glucose tolerance test for, 666–669
prolactin level in, 991–993
Adrenal tumor
abdominal CT of, 404–407
DHEAS and, 542–543
estradiol level in, 589–590
Adrenocarcinoma, 916
Adrenocortical hyperfunction
amino acid levels in, blood test for, 37–38
human growth hormone levels in, 683–684
Adrenocortical insufficiency, 822–824
Adrenocortical tumor, 1085–1086
Adrenocorticosteroid, 400–403
Adrenocorticosteroid insufficiency, 900–902
Adrenocorticotropic hormone (ACTH)
challenge tests and, 7–12
DHEAS and, 542
stimulated, rapid test, 464–467
Adrenogenital syndrome, 466–467
Adult
age-specific communication and, 1267–1268
amino acid screen in, 39–41
beta-2-microglobulin levels in, 879
blood gas analysis in, 221–232
calcium values in, 259–260
carbon dioxide measurement in, 276
complement proteins in, 356
DHEAS and, 542–543
fibrinogen level in, 620–622
follicle-stimulating hormone level in, 628
glucose levels in, 657
G6PD levels and, 662
haptooglobin level in, 685
metanephrine levels in, 871
osteoporosis in, 344
radiography of, 1028–1029
reticulocyte count in, 1042
sodium levels in, 1065
total cholesterol level in, 329–333
total CK in, 472
uric acid level in, 1185–1188
vanillylmandelic acid level in, 1203
vitamin B₁₂ level in, 1217
vitamin C level in, 1227
vitamin E deficiency and, 1222–1224
zinc deficiency in, 1234
Adult lymphoblastic (T-cell) leukemia, HTLV-I and, 722–724
Adulterant, 546
Adult Treatment Panel III (ATP III), cholesterol in, HDL, LDL, 326
AEP (auditory evoked potential), 590–594
Aeromona spp., 507–509
Aerosol lung scan, 807
AFL (amniotic fluid index), 1135–1139
A-fibrinogenemia
aPTT in, 926–929
prothrombin time and, 1008–1011
AIDS. See Acquired immune deficiency syndrome (AIDS)
Airborne precautions, 1283–1284, 1287–1288
Airborne transmission of pathogen, 1278
Air-contrast barium enema, 1157–1159
Airway obstruction, 277–279
Airway resistance, plethysmography and, 950–954
Airway-reactive disorder, 1015–1017
Akinesia, 239–241
Alanine, 39–41
Alanine aminotransferase (ALT), 13–15
Albright-type renal disease, 980–982
Albumin (Alb), 15–18, 876. See also
Microalbumin
calcium and, 259
FT₃ and, 1112
FT₄ and, 1099
glycated, 631–633
macroaggregated, in lung perfusion scan, 804
prealbumin and, 983
protein fractions and, 996
protoporphyrin and, 575
T₃, –binding, 1097
total T₃ and, 1114
total T₄ and, 1101
units of, 996
urine, 876–879
zinc level and, 1235–1236
Albumin/globulin ratio (A/G ratio), 15–18
Alcohol abuse, 380–382, 544–547
alanine aminotransferase levels in, 13–15
aldosterone levels in, 20–22
effect on EEG, 563
FDG-PET scan imaging and, 599
GGT levels with, 670–672
glucose levels and, 659–662
insulin levels with, 745–747
lactic acid levels and, 777–779
PET scan and, 964, 967, 971
plethysmography and, 951
testosterone and, 1085–1086
Alcoholic myopathy, 205–208
Alcoholism
amylase levels in, 52–53
antimitochondrial/antismooth muscle antibody in, 101–102
bilirubin levels, 164–166
calcium release and, 257
chloride values in, 311–314
dye, 624. See also Iodinated dye(s)
edosinophil count in, 573–575
immunoglobulin levels with, 27–28
insulin, 748
intravenous pyelography and, 756
latex, 27–28, 789
pulmonary function study for, 1016–1017
shellfish. See Shellfish allergy
transfusion, 1269–1272
WBC and differential in, 400–403
Alloantibody, platelet, 948–949
Alloimmune disorder, platelet antibodies, 948–949
peripheral neuropathy and, 566–567
platelet count in, 380–382
potassium levels and, 975–978
prealbumin and, 983–984
protein level in, 996–998
RBC indices in, 389–391
RBC morphology in, 393–396
reticulocyte count for, 1043–1044
skeletal muscle CK-MM and, 474–475
total cholesterol level in, 330–333
triglyceride levels and, 1109–1111
uric acid level in, 1186–1188
vitamin B₁ and, 1227, 1228
vitamin B₆ and, 1228
vitamin B₁₂ and, 1218–1219
vitamin C and, 1228
WBC and differential in, 399–403
withdrawals from, phosphorous levels and, 940–942
Aldolase (ALD), 18–19
Aldosterone, 19–22. See also
Hyperaldosteronism;
Hypoaldosteronism
potassium levels and, 975–978
Alkali ingestion, 84–86, 227–232
Alkaline phosphatase (ALP)
importance of, 795
isoenzyme and, 23–26
osteocalcin levels and, 903
peritoneal fluid and, 936–938
Alkalosis
anion gap and, 84–86
blood gas analysis in, 225
calcium values in, 261–263
carbon dioxide levels in, 278–279
cloride values in, 308–310
metabolic. See Metabolic alkalosis
potassium levels and, 975–978
respiratory. See Respiratory alkalosis
Allen test, 1259
Allergen profile, 26–28
Allergen-specific immunoglobulin E, 26–28
Allergic alveolitis, extrinsic, 727
Allergic rhinitis, 27–28
Allergy
dye, 624. See also Iodinated dye(s)
eosinophil count in, 573–575
immunoglobulin levels with, 27–28
insulin, 748
intravenous pyelography and, 756
latex, 27–28, 789
pulmonary function study for, 1016–1017
shellfish. See Shellfish allergy
transfusion, 1269–1272
WBC and differential in, 400–403
Alloantibody, platelet, 948–949
Alloimmune disorder, platelet antibodies, 948–949
Alloimmunization, transfusion related, 1272

ALP. See Alkaline phosphatase (ALP)

Alpha-amino-adipic acid, 39–41

Alpha-amino-N-butyric acid, 39–41

Alpha,-antitrypsin, 136–139

Alpha,-antitrypsin phenotyping, 136–139

Alpha-chain substitution, 690

Alpha-fetoprotein (AFP), 613–617

aminof orm fluid analysis and, 47, 48

quad-marker testing and, 613, 715

triple-marker testing and, 613, 614, 715

Alpha,-globulin, 996–998

Alpha,-globulin, 996–998

Alpha-microglobulin-1 protein, placental, 47

ALS (amyotrophic lateral sclerosis)
electromyography for, 566–567

muscle biopsy for, 205–208

ALT (alanine aminotransferase), 13–15

Altitude
FT3 and, 1112–1113

hematocrit in, 369–372

hemoglobin in, 374–378

Alveolar hemorrhage, 103–104

Alveolar/arterial gradient (A/a gradient), 29–32

Alveolitis, extrinsic allergic, 727

Alzheimer’s disease
FDG-PET scan for, 598–601

MRI for, 837–839

PET scan for, 963–966

Alzheimer’s disease markers, 32–34

AMA (antimitochondrial antibody), 100–102

AMA (antimitochondrial muscle antibody), 100–102

Amblyopia

Intraocular muscle function and, 750–752

visual field test for, 1215–1217

Ambulatory monitoring, 707–709

Amebiasis, 603–604

Anal canal mucosa, proctosigmoidoscopy and, 985–988

Anal culture, 492–497

Anal fissure

fecal analysis for, 603–604

proctosigmoidoscopy for, 985–988

Anal fistula, 985–988

Anal papillae, proctosigmoidoscopy and, 985–988

Analoscopy, 985–988

Anaphylaxis, 1270

immunoglobulin levels in, 27–28
WBC and differential in, 400–403
Anastomosis, proctosigmoidoscopy and, 985–988
Ancylostoma duodenale infection, 908–909
Androgen resistance syndrome, 1085–1086
Anemia, 373–378, 383–388, 457–458
aldolase levels in, 18–19
alkaline phosphatase levels in, 25–26
amino acid levels in, urine test for, 40
antithyroglobulin/antithyroid peroxidase antibody in, 112–113
aplastic. See Aplastic anemia
apolipoprotein B and, 141–143
bilirubin levels in, 164–166
blood gas analysis in, 226–232
bone marrow biopsy for, 174–177
calcitonin stimulation test for, 257–259
cholinesterase enzyme in, 1030–1032
complement protein levels in, 357–358, 359–360
copper levels in, 461–463
DAT and, 459–460
drug-induced, 457–458
dyserythropoietic, 683
PNH and, 685
erthrocyte sedimentation rate and, 577–578
erythropoietin level in, 581–582
fetal fat and, 606–608
ferritin level in, 609–610
folate level in, 626–628
free erythrocyte protoporphyrin test for, 576–577
gastric acid stimulation test and, 640–642
gastrin stimulation test for, 645–647
glycated hemoglobin AIC and, 673–674
G6PD levels in, 663
Ham’s test for, 683
hematocrit in, 369–372
hemoglobin C Harlem, 1060–1061
hemoglobin electrophoresis for, 689–691
hemoglobin in, 374–378
hemolytic. See Hemolytic anemia
hemosiderin levels in, 692–693
human chorionic gonadotropin level in, 716–717
hypochromic, 461–463
RBC indices in, 390–391
total iron-binding capacity and, 765–766
intrinsic factor antibody and, 759–760
iron level in, 761. See also Iron-deficiency anemia
lactate dehydrogenase levels in, 775–776
LAP levels in, 795–797
LDLC level in, 327–329
lead intoxication and, 790
macrocytic, 389–391
megaloblastic. See Megaloblastic anemia
microangiopathic, 692–693
microcytic, 461
nonspherocytic
G6PD levels in, 663
pyruvate kinase levels in, 1020
osmotic fragility and, 902–903
pernicious. See Pernicious anemia
platelet count in, 379–382
posthemorrhagic, 379–382
pseudocholesterolase level in, 1011–1012
pulse oximetry and, 1018–1019
pyruvate kinase levels in, 1020
RBC indices in, 389–391
RBC morphology in, 393–396
refractory, 395–396
reticulocyte count for, 1043–1044
sickle cell screen and, 1060. See also Sickle cell anemia
sideroblastic. See Sideroblastic anemia
total cholesterol level in, 331–333
total iron-binding capacity and, 765–766
transferrin level in, 1106–1108
upper GI series for, 1172–1174
uric acid level in, 1189–1191
vitamin B12 and, 1218–1219
vitamin C and, 1228
vitamin E and, 1222–1224
WBC and differential in, 400–403
Anencephaly, AFP and, 446–449
Anesthesia
cholinesterase deficiency and, 1030
pseudocholesterolase deficiency and, 1011–1012
uterine fibroid embolization and, 1199–1202
Aneurysm, 79–82
abdominal angiography of, 58–61
abdominal CT of, 404–407
aortic. See Aortic aneurysm arterial
abdominal angiography of, 58–61
carotid angiography of, 67–69
brain CT of, 417–420
carotid angiography of, 67–69
cerebral, 837–839
coronary angiography of, 70–73
CT angiography of, 408–412
Aneurysm (continued)
  echocardiography for, 551–554
  esophagogastroduodenoscopy and, 587
  fluorescein angiography for, 623–625
  fundus photography for, 634–635
  kidney CT for, 441–445
  left ventricle, 886
  MRI for, 833–835, 836–839, 859–861
  myocardial infarction scan and, 886
  PET scan for, 963–966
  pituitary CT of, 437–441
  pulmonary angiography of, 74–77
  renal artery, 79–82, 442–445
  transesophageal echocardiography of, 555–557
  ultrasonography for, 1129–1131
  ventricular, 551–554

Angiitis, 103–104
Angina pectoris, 1117–1118
Angiodysplasia, 651–654
Angioedema, 357–358
Angiography
  computed tomography, 408–412
  fluorescein, 623–625
  magnetic resonance, 829–831, 836–838
  of pancreas, 851
  of pelvis, 855
  of abdomen, 57–61
  of adrenal gland, 62–65
  of heart, 70–73
  of kidney, 78–82
  of neck/cervical area, 66–69
  of pulmonary vasculature, 74–77
  patient's age as factor in, 59, 63, 67, 71, 75, 79
  sensitivity to iodinated dye and, 59, 63, 67, 71, 74, 79
Angioplasty, 58, 66
Angiotensin, 1035–1036
Angiotensin-converting enzyme (ACE), 82–83, 133–134
Angiotensinogen, 1035–1036
Angle-closure glaucoma, 752–755
Anion, 974
Anion gap, 83–86
Anisocytosis, 363, 392
Ankle, arthrogram of, 143–146
Ankle pressure, plethysmography and, 950–954
Ankylosing rheumatoid spondylitis
  copper levels in, 462–463
  human leukocyte antigen and, 721–722
  MRI in, 848
  radiography in, 1028
  spine CT in, 446
Anomalous atrioventricular excitation, 595–597
Anorchia, 815–816
Anorectal abscess, 985–988
Anorectal infection, 517–519
Anorexia nervosa
  apolipoprotein B and, 141–143
  bilirubin levels in, 164–166
  blood gas analysis in, 226–232
  follicle-stimulating hormone level in, 629–631
  gastric emptying scan for, 643–645
  human growth hormone levels in, 683–684
  LDLC level in, 327–329
  luteinizing hormone secretion and, 815–816
  potassium levels and, 976–978
  prolactin level in, 991–993
  total cholesterol level in, 330–333
  triglyceride levels and, 1109–1111
  WBC and differential in, 400–403
Anovulation
  DHEAS and, 542–543
  testosterone and, 1085–1086
Anoxia, 226–232
ANP (atrial natriuretic peptide), 152–153, 254
ANS (autonomic nervous system), 288–290
Anserine, 39–41
Antacids, 822–824
Anterior chamber
  gonioscopy of, 675–677
  split-lamp biomicroscopy of, 1061
Anterior pituitary hypofunction, 629–631
Anti-A antibody, 233
Antianginal effectiveness, 595–597
Antiarrhythmic drugs, 86–92
Antiarrhythmic effectiveness, 595–597
Anti-B antibody, 233
Antibiotic therapy, 92–96
  throat/nasopharyngeal culture and, 510
  urine culture and, 512
  vitamin K and, 1225–1226
Antibody(ies). See also Immunoglobulin entries
  acetylcholine receptor, 1–3
  anticientromere, 104–108
  anti-cyclic citrullinated peptide, 96–98
  anti-DNA, 104–108
  antinuclear antibody, 104–108
  antithrombin III, 96–98
  antithrombin III deficiency, 96–98
  anti-glomerular basement membrane, 99–100
  antimitochondrial and antismooth muscle, 100–102
  antineutrophilic cytoplasmic, 102–104
antinuclear, 104–108
antiscleroderma, 104–108
antisperm, 108–110
antistreptolysin O, 110–111
antithyroglobulin/antithyroid peroxidase, 112–113
cardiolipin, 113–115
gliadin, 115–117
hepatitis A, 693–695
hepatitis B, 695–698
hepatitis C, 698–700
hepatitis D, 700
Jo-1, 104–108
parvovirus, 517–519
platelet, 948–949
rubella, 1053–1054
rubeola, 1053–1054
Toxoplasma, 1104
varicella, 1205–1207
Antibody screen, 459–460
Anticardiolipin antibody (ACA), 113–115
Anticentromere antibody, 104–108
Anticholinergics
electromyography and, 566
sphincter muscle electromyography and, 568–570
Anticoagulant therapy
aPTT and, 926–929
cholinesterase enzyme and, 1031
goal of, 1007
protein C and, 999–1001
Anticonvulsant drugs, 117–121
effect on EEG, 563
toxicity of, 261–263
Anti-cyclic citrullinated peptide antibody, 96–98
Anti-D antibody, 233
Antideoxyribonuclease-B, streptococcal, 122–124
Antidepressant drugs, 124–128
Antidiuretic hormone (ADH), 128–130
chloride values and, 308–310
magnitude level and, 823–824, 825–828
sodium levels and, 1065–1067
syndrome of inappropriate secretion of, 129–130
osmotic concentration and, 900–902
Anti-DNA antibody, 104–108
Anti-ds DNA, 104–108
Antiestractable nuclear antigen, 104–108
Ant-GBM, 99–100
Antigen/antibody, antieextractable nuclear, 104–108
Antiglobulin testing
direct, 457–458
indirect, 459–460
Anti-glomerular basement membrane antibody, 99–100
Antimanic drugs, 131–134
Antimetabolite therapy, 389–391
Antimicrobial removal device (ARD), 498
Antimicrobial therapy, 500–501
Antimitochondrial and antismooth muscle antibody, 100–102
Antimitochondrial/antismooth muscle antibody, 100–102
Antineoplastic drugs, 400–403
Antineutrophilic cytoplasmic antibody, 102–104
Antinuclear antibody (ANA), 104–108
Antiphospholipid syndrome, 106–108, 113–115
Antiplatelet antibody, 948
Antiplatelet therapy, 539
Antipsychotic drugs, 131–134
Antipyretic drugs, 54–57
Anti-ribonucleoprotein, 104–108
Anti-Scl 70, 106–108
Antiscleoderma antibody, 104–108
Antismooth muscle antibody (ASMA), 100–102
Antisperm antibody, 108–110
Antistreptolysin O antibody, 110–111
Antithrombin antibody, 811
Antithrombin III (AT-III), 134–136
Antithyroglobulin antibody, 112–113
Antithyroid peroxidase antibody, 112–113
Antrum syndrome, retained, 639–642
Anuria, quinidine toxicity and, 86–92
Anus, 985–988
Anxiety
blood gas analysis in, 227–232
carbon dioxide levels in, 278–279
effect on EKG, 560
exercise stress test and, 595–597
FDG-PET scan imaging and, 599
RBC count in, 384–388
Anxiolytic, 563
Aortic aneurysm, 587
abdominal CT of, 404–407
CT angiography of, 408–412
MRI for, 835–835, 843–846
splenic CT of, 450–453
thoracic CT for, 454–456
Aortic atherosclerosis, 70–73
Aortic coarctation, 844–846
Aortic dissection
coronary angiography of, 71–73
MRA for, 829
MRI for, 844–846
transesophageal echocardiography of, 555–557
Aortic lymph node, ultrasonography of, 1150–1152
Aortic valve abnormality, 551–554
Aortitis, 70–73
Aortoduodenal fistula, 651–654
Aplasia, 1020
Aplastic anemia
  bone marrow biopsy for, 174–177
eosinophil count in, 573–575
hemoglobin electrophoresis for, 689–691
iron level in, 761
LAP levels in, 795–797
MRI for, 848–850
platelet count in, 380–382
RBC morphology in, 393–396
reticulocyte count for, 292–293
WBC and differential in, 400–403
Aplastic crisis, parvovirus B19 and, 929–931
Apnea
  ECG and, 557–561
  pulse oximetry and, 1018–1020
Apolipoprotein A and B, 140–143
Appendectomy, laparoscopic, 782–785
Appendicitis
  abdominal CT of, 404–407
  abdominal laparoscopy for, 782–785
  barium enema for, 157–159
  ultrasonography for, 1156–1158
  WBC and differential in, 399–403
Appendix, 1155–1158
Appetite, anticonvulsant toxicity and, 119–121
aPTT (activated partial thromboplastin time), 811, 925–929
Aqueous humor, of eye, 752–755
ARD (antimicrobial removal device), 498
ARDS (acute respiratory distress syndrome), A/a gradient and a/A ratio in, 30
Areflexia, magnesium and, 823
Areola, scaly skin of, 1074
Arginine, 39–41
Argonz-Del Castillo syndrome, 991–993
Arm
  venipuncture of, 1255
  x-ray of, 1027–1029
Arrhythmia(s)
  abdominal laparoscopy and, 783
  aspartate aminotransferase levels in, 150–152
drugs for, 86–92
ECG for, 558
effect on echocardiography, 552, 556
fluorescein angiography for, 623–625
pulmonary angiography of, 74–77
proctosigmoidoscopy and, 986
vertebroplasty and, 1212
ART (automated reagin testing), 1081
Arterial aneurysm
  abdominal angiography of, 58–61
carotid angiography of, 67–69
Arterial atherosclerotic obstruction, 950–954
Arterial blood gases, 221–232, 1015
Arterial blood oxygen saturation (SPO2), 1018–1020
Arterial calcification
  plethysmography for, 950–954
  ultrasonography for, 1129–1131
Arterial embolism, 950–954
Arterial fistula, 67–69
Arterial hypoplasia, 74–77
Arterial infarction, 79–82
Arterial injury, 1040–1042
Arterial occlusion
  cardiolipin antibody in, 114
  D-dimer in, 539
Arterial/alveolar oxygen ratio (a/A ratio), 29–32
Arterial-venous shunt, 30–32
Arteriography. See Angiography
Arteriosclerosis, 1234–1236
Arteriovenous fistula, 58–61
Arteriovenous malformation (AVM), 837–839
brain CT of, 417–420
pulmonary angiography of, 74–77
Arteriovenous shunt, 623–625
Arteritis, temporal, ESR and, 577–578
Artery. See also specific arteries
  Dopper ultrasonography of, 551–554
  plethysmography of, 950–954
Arthritis, 1078–1080. See also Rheumatoid arthritis
  arthrogram for, 143–146
  arthroscopy for, 147–149
  bacterial, 1078–1080
degenerative
  arthroscopy in, 147–149
  synovial fluid analysis in, 1078–1080
  haptoglobin level in, 686–687
hemophilic, 1078–1080
MRI for, 848–850
parvovirus and, 929–931
psoriatic, 721–722
radiography of, 1028–1029
rheumatoid. See Rheumatoid arthritis
synovial fluid analysis and, 1078–1080
tuberculous, 1078–1080
white blood cell scan for, 1231–1233
Arthrocentesis, 1077
Arthrogram, 143–146
Arthroscopy, 146–149
Artificial ventilation, 227–232
Asbestosis, 1016–1017
A-scan ultrasonography, 1131–1133
Ascariasis, 908–909
Ascariasis infection, 908–909
Ascites
abdominal laparoscopy for, 782–785
KUB study for, 771–772
MRI for, 855–857
peritoneal fluid analysis for, 935–938
ultrasonography for, 1155–1158
Ascites fluid analysis, 935
Ascorbic acid, 1226
Aseptic meningitis, 883
ASMA (antismooth muscle antibody), 100–102
Asparagine, 39–41
Aspartate aminotransferase (AST), 149–152
Aspartic acid, 39–41
Aspergilloma, 74–77
Aspiration
cyst, breast ultrasonography for, 1142–1144
suprapubic
for bacteria culture, 513
for urinalysis, 1198
for urine cytology, 536
Aspiration biopsy. See Fine-needle aspiration biopsy
Aspiration pneumonia, 530–534
Aspiration scan, 643–645
Asplenia, 902–903
AST (aspartate aminotransferase), 149–152
Atrophic changes, colposcopy of, 353–355
Atrophy
Audiogram, 156
Audiometry, 153–156
Attention-deficit hyperactivity disorder (ADHD), 126–128
Asthmatic shock, 277–279
Astigmatism, 1032–1035
Asymptomatic gluten-sensitive enteropathy, 116–117
Ataxia-telangiectasia, 734–735, 737–738
Atelectasis, 30–32
blood gas analysis in, 226–232
chest x-ray for, 302–303
lung perfusion scan for, 805–807
lung ventilation scan for, 808–810
plethysmography for, 951–954
Atherectomy, 58, 66. See Arterial stenosis
Atherosclerosis
CRP assay for, 470–472
renogram for, 1039–1042
ultrasonography for, 1126–1128
AT-III (antithrombin III), 134–136
Atopic dermatitis, 27–28
ATP (adenosine triphosphate), 902–903
Atransferrinemia, 86–92, 1106–1108
Atresia
ultrasonography for, 1136–1139
vitamin E and, 1223–1224
Atrial hypertrophy, 559–561
Atrial mural thrombus
echocardiography for, 551–554
transesophageal echocardiography of, 554–557
Atrial natriuretic peptide (ANP, atrial natriuretic factor, atrial natriuretic hormone), 152–153, 254
Atrial septal defect, 805
Atrial tumor
echocardiography for, 551–554
transesophageal echocardiography of, 554–557
Atrophic changes, colposcopy of, 353–355
Atrophy
Audiogram, 156
Audiometry, 153–156
Auditory brainstem response (ABR), 590
Auditory canal, 905–907
Auditory evoked potential (AEP), 590–594
Auditory nerve, MRI of, 836
myocardial perfusion heart scan and, 890
plethysmography for, 951–954
potassium levels and, 975–978
pulmonary function study for, 1016–1017
vitamin B12 and, 1228
WBC and differential in, 400–403
WBC differential count for, 521–523
Auditory nerve lesion, ABR and, 590
Auditory system, 1237
Auer rod, 366
Autoantibody, platelet, 948–949
Autoimmune disorder
  antithryroglobulin/antithyroid peroxidase antibody in, 112–113
  beta2–microglobulin levels in, 880–883
  complement protein levels in, 359–360
Autoimmune hemolysis, 686–687
Autoimmune hemolytic anemia, 357–360, 457–458
Autoimmune hepatitis
  antimitochondrial/antismooth muscle antibody in, 101–102
  cryoglobulin detection in, 485–486
Autoimmune liver disease, 103–104
Autoimmune thyroiditis, 357–358
Automated reagin testing (ART), 1081
Automobile, lead and, 789–791
Autonomic nervous system dysfunction, 288–290
Avascular necrosis, 848–850
AVM. See Arteriovenous malformation (AVM)
Axillary node
  biopsy of, 202–205
  lymphangiogram of, 818–821
Azidothymidine (zidovudine), 881–883
Azoospermia, 1057–1059
Azotemia
  osmotic concentration in, 899–902
  sodium levels and, 1068–1071
  sodium levels in, 1065–1067
  AZT (zidovudine), 881–883
Bacterial infection
  albumin/globulin ratio, 16–18
  complement protein levels in, 357–358
  CRP assay for, 470–472
  culture for, 492–497
  fecal analysis for, 603–604
  platelet count in, 380–382
  stool culture for, 507–509
  synovial fluid analysis and, 1078–1080
Bacterial meningitis, 295–298
Bacterial organism, 677–679
Bacterial overgrowth
  D-xylose tolerance test for, 547–550
  oxalate levels in, 910–912
  vitamin B12 and, 1218–1219
Bacterial pericarditis, 932–934
Bacterial peritonitis, 936–938
Bacterial pneumonia
  bacterial culture for, 500–501
  cause of, 502
Bacterial vaginosis, 915
Bacteriological sputum testing, 1119
Bacteroides, 494–497
BAEP (brainstem auditory evoked potential), 590
BAER (brainstem auditory evoked response), 590
Baker’s cyst, 147–149
Balloon angioplasty, myocardial perfusion scan and, 890
Balloon angioplasty, myocardial perfusion scan and, 890
Barbiturate
  abuse of, 544–547
  effect on ECG, 560
Bard BTA, 218–219
Barium
  abdominal laparoscopy and, 783
  esophagogastroduodenoscopy and, 587
  fecal fat and, 607
  gastric emptying scan and, 643
  gastrointestinal blood loss scan, 651
  gynecologic laparoscopy and, 786
  lymphangiography and, 819
  proctosigmoidoscopy and, 986
  radiography and, 1028
  retrograde ureteropyelography and, 1046
  stool analysis and, 908
  ultrasonography and, 1137, 1140, 1146, 1150, 1164
  uterine fibroid embolization and, 1200
vertebroplasty and, 1212

white blood cell scan and, 1231

Barium enema, 157–159

Barium sulfate, 1171

Barium swallow, 160–162

*Bartonella henselae*, 577–578

Bart’s hemoglobin, 690

Barter’s syndrome

aldoosterone levels in, 20–22
magnesium level and, 825–828
renin value in, 1036–1039

Basal acid output (BAO), 639–642

Basal cell carcinoma, 212–214

Basophil, 733

Basophil cell, 398–399

Basophilic leukemia, 639–642

Basophilic stippling, 392, 394

Battery, lead in, 789–791

BE (barium enema), 157–159

Beckwith-Wiedemann syndrome, 334

Bell’s palsy, 566–567

Bence Jones screening test, 731

Benign meningioma, 837–839

Benign prostatic hypertrophy (BPH)
cystoscopy in, 523–526
PSA levels and, 994–995
ultrasonography for, 1159–1160

Benign tumor

colonoscopy for, 347–350
esophagastroduodenoscopy for, 586–589
liver and spleen scan for, 801–803
thyroid scan for, 1090–1092
ultrasonography for, 1162–1163

Benzene toxicity, 960–962

Benzodiazepine abuse, 544–547

Beriberi, 1227

electromyography for, 566–567

Bernard-Soulier syndrome

bleeding time in, 220
platelet count in, 380–382

Bernstein test, 582–583, 585

Berylliosis, 260–263

Beta cell failure, 745–747

Beta cell transplant, 468–469

Beta-alanine, 39–41

Beta-cell failure, 39–41

Beta-cell substitution, 690

Beta-globulin, 996–998

Beta-HCG, 714–717

Beta-hemolytic streptococcus
bacterial culture for, 494–497
throat/nasopharyngeal culture for, 509–511

Beta-hydroxybutyrate, 768

Beta₂-microglobulin, 878–883

Beta-subunit-HCG, 714–717

Bethesda system, 915–916

Bicarbonate, 223, 224

in acidosis, 225
in alkalosis, 225

Biclonal gammopathy, 731

Bicorne uterine, 728–730

Bilateral adrenal hyperplasia, 63–65

Bile duct obstruction, common
amylase levels in, 52–53
bilirubin levels in, 164–166
percutaneous transhepatic cholangiography for, 315–318

Bile leak, 701–704

Bile salt deficiency, 606–608

Biliary atresia
alkaline phosphatase levels in, 24–26
hepatoportal scan for, 701–704
vitamin E and, 1223–1224

Biliary cirrhosis
antineutrophilic cytoplasmic antibodies in, 103–104
ceruloplasmin levels in, 299–300
copper levels in, 462–463
HDLc level in, 326–329
osteocalcin levels and, 904–905

Biliary duct obstruction, common,
1148–1149

Biliary enteric bypass patency, hepatobiliary scan and, 701–704

Biliary fistula, 701–704

Biliary leak, 701–704

Biliary obstruction
haptoglobin level in, 686–687
prothrombin time and, 1008–1011

Biliary sclerosis, 315–318

Biliary tract, 412–416, 1147–1149

Biliary tract disease, 910–912

Biliary tract obstruction
alanine aminotransferase levels in,
15–15
alkaline phosphatase levels in, 24–26
aspartate aminotransferase levels in, 150–152
bilirubin levels in, 164–166

Bilirubin, 162–166
amniotic fluid analysis for, 47–51
hepatoportal scan and, 702
protoporphyrin and, 575
transcutaneous measurement of, 163
urine, 1194, 1197

Bilirubin fraction, 162–166

Bing test, 1122–1124

Binocularity, 591–594

Biophysical profile (BPP), 1134–1139

Biopsy

aspiration. See Fine-needle aspiration

biopsy

bladder, 166–169

bone, 170–172

bone marrow, 173–177
Biopsy (continued)

biopsy, 177–181
cervical tissue, 182–185
chorionic villus, 185–188
colonoscopy and, 426
corneal, 182–185
curettage, 212–214
excision, 212–214
fine-needle aspiration. See Fine-needle aspiration biopsy
intestinal, 188–190
kidney, 191–194
liver, 194–197
lung, 197–201
lymph node, 202–205
muscle, 205–208
needle. See Fine-needle aspiration biopsy; Needle biopsy
open. See Open biopsy
prostate, 208–211
punch, 182, 212
shaving, 212–214
skin, 212–214
stereotactic, 1074–1077
thyroid, 215–217
vacuum-assisted, 1074
Biopsy specimen, 677–679
Bipolar disease
anticonvulsants for, 119–121
antidepressants for, 126–128
Birth defects
alcohol abuse and, 544–547
chromosome analysis for, 333–336
Birth weight
alpha1–fetoprotein and, 613–617
biophysical profile and, 1134–1139
Bismuth, 1175
Bitter taste, GER and, 643–645
Black feces, analysis of, 602–602
Bladder
cystometry of, 520–523
cystoscopy of, 523–526
intravenous pyelography of, 755–758
ultrasonography of, 1139–1141
voiding cystourethrography of, 526–529
Bladder biopsy, 166–169
Bladder calculi
cystoscopy for, 524–526
pelvic CT of, 433–437
Bladder cancer. See also Bladder tumor markers for, 218–220
skeletal muscle CK-MM and, 474–475
urinary calcium levels in, 268–271
Bladder distention, 771–772
Bladder diverticulum, 1140–1141
Bladder fullness, 521
Bladder function, urodynamic testing of, 520–523
Bladder injury, voiding cystourethrography in, 526–529
Bladder paralysis, 521
Bladder perforation/rupture, 936–938
Bladder stones
cystoscopy for, 524–526
pelvic CT of, 433–437
Bladder trauma
KUB study for, 771–772
voiding cystourethrography for, 527–529
Bladder tumor. See also Bladder cancer
intravenous pyelography for, 756–758
ultrasonography for, 1156–1158
voiding cystourethrography for, 527–529
Bladder tumor antigen (BTA), 218
Blastocystis hominis infection, 908–909
Blastomyces, 198–201
Blastomycosis, 250–253
Bleach, urine drug screen and, 546
Bleb, pulmonary angiography of, 74–77
Bleeding. See Hemorrhage
Bleeding disorders
abdominal laparoscopy and, 783
aPTT in, 926–929
CBC and, 368
cystoscopy and, 524
fibrin degradation product and, 618–619
Hgb and, 374
myocardial perfusion heart scan and, 890
natural products affecting, 1275
proctosigmoidoscopy and, 986
prothrombin time and, 1008–1011
radiofrequency ablation and, 1025
RBC count and, 384
RBC indices and, 389
RBC morphology and, 393
upper GI, 586–589
venogram and, 1208
vertebroplasty and, 1212
vitamin K and, 1225–1226
voiding cystourethrography and, 527
WBC count and, 399
Bleeding time, 220
Blepharitis, 1062–1064
Blepharochalasis, 1215–1217
Blighted ovum, ultrasonography of, 1136
Blind loop syndrome, 626–628
Blinking, Schirmer tear test and, 1055–1056
Blood clot
cystoscopy for, 523–526
MRI for, 855–857
proctosigmoidoscopy and, 986
retrograde ureteropyelography for, 1045–1048
Blood clotting, 825. See also Coagulation entries
Blood flow
decreased, PET scan for, 967–970
echocardiography of heart, 551–554
myocardial perfusion scan for,
888–889
transesophageal echocardiography of, 555–557
Blood gas analysis, 221–232
Blood groups and antibodies, 233–237
Blood loss. See also Bleeding disorders;
Hemorrhage
anemia due to, platelet count in,
379–382
bone marrow biopsy for, 174–177
gastrointestinal, scan for, 651–654
glycated hemoglobin A1C and,
673–674
hematocrit in, 369–372
hemoglobin in, 374
iron level with, 762–764
reticulocyte count for, 1043–1044
Blood pool imaging, 237–241
Blood specimen
collection equipment, 1257
collection procedure for, 1257–1260
order of draw, 1260–1261
patient preparation for, 1251–1253
site selection for, 1253–1257
Blood sugar, 657
Blood supply loss, 474–475
Blood test, 1119–1121
Blood transfusion. See Transfusion
Blood typing, 233–237
Blood vessel(s)
anticardiolipin antibody in, 114
CT of, 408–412
lower extremity ultrasonography of,
1169
MRA of, 828–831
Bone
ALP in, 24
biopsy of, 170–172
MRI of, 847–850
phosphorus in, 939, 942
radiography of, 1027–1029
radionuclide scan of, 245–248
zinc in, 1234
Bone cancer
calcium values in, 260–263
ceruloplasmin levels in, 299–300
urinary calcium levels in, 268–271
Bone conduction testing, 156
Bone degeneration, 1028–1029
Bone disease
ALP in, 24
chest x-ray in, 301
osteocalcin and, 903–905
scan for, 245–248
urine calcium and, 268, 269
vitamin D and, 1220
Bone marrow
erythropoietin and, 580
fungal culture of, 514–516
iron storage in, 764–765
Bone marrow biopsy, 173–177
Bone marrow depression, 400–403
WBC and differential in, 400–403
Bone marrow disease, MRI for, 848–850
Bone marrow failure
eosinophil count and, 573–575
RBC count in, 384–388
WBC and differential in, 400–403
Bone marrow hyperplasia, 369–372
Bone marrow transplant, 380, 1043–1044
Bone metabolism, osteocalcin and,
903–905
Bone metastasis, 939–942
Bone mineral densitometry (BMD),
242–245
Bone necrosis, 245–248
Bone neoplasm, 269–271
Bone radiography, 1027–1029
Bone scan, 245–248
Bone spur, 1028–1029
Bordetella, 509–511
Borrelia burgdorferi, 816
Botulism, 507–509
Bowel. See Colon entries; Intestinal entries;
Small bowel entries
BPH (benign prostatic hypertrophy)
cystoscopy in, 523–526
PSA levels and, 994–995
ultrasonography for, 1159–1160
BPP (biophysical profile), 1134–1139
BPP ultrasonography, 1134–1139
Bradyarrhythmia, Holter monitor and,
707–709
Bradycardia
  electrocardiogram for, 559–561
  exercise stress test for, 595–597
  heroin and, 546
  potassium levels and, 976–978
Brain. See also Cerebral entries
  acetylcholinesterase in, 1030
  computed tomography of, 416–420
  electroencephalography of, 562–564
  evoked potentials and, 590–594
  FDG-PET scan of, 598–601
  MRI of, 836–839
  PET scan of, 962–966
  Brain CK-BB, 473–474
  Brain death, 562–564
  Brain infarct. See Cerebral infarction
  Brain injury, 591–594
  Brain ischemia, 409–412
  Brain natriuretic peptide (BNP), 254–255
  Brain trauma, 599–601
  Brain tumor
    antidiuretic hormone and, 129–130
    carbon dioxide levels in, 277–279
    EEG determining, 563–564
    visual field test for, 1215–1217
  Brainstem auditory evoked potential (BAEP), 590
  Brainstem auditory evoked response (BAER), 590
  Brainstem tumor, 591–594
  Branched-chain ketonuria, 767–770
  BRCA1, 840
  BRCA2, 840
Breast
  FDG-PET scan of, 598–601
  mammography of, 861–864
  MRI of, 839–843
  ultrasonography for, 1142–1144
  Breast abscess, 1142–1144
  mammogram of, 861–864
  MRI of, 839–843
  Breast biopsy, 177–181
  Breast cancer
    alkaline phosphatase levels in, 24–26
    beta_2-microglobulin levels in, 880–883
    biopsy in, 177–181, 1074
    calcitonin stimulation test for, 257–259
    cancer antigen levels in, 284, 285
    DNA ploidy in, 177, 178
    ER assays in, 177, 178
    FDG-PET scan for, 599–601
    ferritin level in, 609–610
    FISH technique for chromosome abnormalities in, 177
    HER-2/neu oncoprotein in, 177, 178
    human chorionic gonadotropin level in, 716–717
    Ki67 in, 177, 178
    markers for, 177, 178
    P53 in, 177, 178
    PCNA in, 177, 178
    PR assays in, 177, 178
    receptor assays in, 177, 178
    SPF in, 177, 178
    stereotactic biopsy for, 1074
    ultrasonography for, 1143–1147
    urinary calcium levels in, 268–271
    Breast cancer gene, 840
    Breast cyst
      mammography of, 861–864
      MRI of, 839–843
      ultrasonography of, 1142–1144
    Breast disease
      CEA and, 283
      mammogram of, 861–864
    Breast hematoma, mammogram of, 861–864
    Breast implant
      mammography and, 863
      MRI and, 840
      rupture of, 840
    Breast pain, mammogram in, 861
    Breast self-examination, 862
    Breastfeeding, 991–993
    Breath test, 1175–1177
    Breech position (of fetus), 1136–1139
    Bronchial diverticulum, 250
    Bronchial provocation, 1015
    Bronchial stenosis, 250–253
    Bronchial washing, 514–516
    Bronchiectasis
      mycobacteria culture/smear for, 488
      pulmonary angiography of, 74–77
      pulmonary function study for, 1016–1017
    Bronchitis
      angiotensin-converting enzyme in, 82–83
      blood gas analysis in, 226–232
      carbon dioxide levels in, 277–279
      chest x-ray for, 302–303
      lung perfusion scan for, 805–807
      lung ventilation scan for, 808–810
      plethysmography for, 951–954
      pulmonary function study for, 1016–1017
    Bronchoconstriction, 226–232
    Bronchogenic carcinoma. See also Lung cancer
      lung ventilation scan for, 808–810
      mediastinoscopy for, 868–871
    Bronchopulmonary aspergillosis, 734–735
    Bronchoscopy, 249–253, 532
    Bronchospasm, 30–32
Bronchus, oat cell tumor of, 724–726
Bruise, vitamin K and, 1225
BTA (bladder tumor antigen), 218
B-type natriuretic peptide (BNP), 254–255
Budd-Chiari syndrome, liver-spleen scan in, 801–803
Bulimia nervosa, 126–128
Bullae, pulmonary angiography of, 74–77
Bullet, lead in, 789–791
Bullous keratopathy, 913–914
BUN (blood urea nitrogen), 1177–1180
BUN/creatinine ratio, 476, 1177–1180
Bundle branch block
electrocardiogram for, 559–561
myocardial perfusion heart scan and, 890
Burkitt’s lymphoma, 260–263
infectious mononucleosis and, 742–744
Burn(s)
alanine aminotransferase levels in, 13–15
albumin/globulin ratio, 16–18
amino acid levels in, blood test for, 37–38
chloride values in, 308–310
complement protein levels in, 359–360
copper levels in, 462–463
glucagon level in, 655–657
hematocrit in, 368–372
hemoglobin in, 374–378
hemosiderin levels in, 692–693
immunoglobulin E level in, 737–738
ionized calcium values in, 265–267
LDLC level in, 327–329
phosphorus levels in, 940–942
platelet count in, 380–382
potassium levels and, 975–978
protein level in, 996–998
sodium levels in, 1065–1067
total cholesterol level in, 331–333
WBC and differential in, 400–403
zinc level in, 1235–1236
Burnett’s syndrome, 261–263
Burr cell, 363, 392
Bypass graft
electrocardiogram for, 559–561
myocardial perfusion scan and, 890
C-14 breath test, 1175–1177
C3 complement, 356–358
C4 complement, 356–358
CA 19–9, 282–284
CA 27.29, 282–284
CA 125, 282–284
Cabot rings, 364, 392
CAD. See Coronary artery disease (CAD)
Cadmium poisoning, 880–883
Caffeine
effect on EEG, 563
FDG-PET scan imaging and, 599
PET scan and, 964, 967, 971
semen analysis and, 1058
CAH. See Congenital adrenal hyperplasia (CAH)
Calcification(s)
KUB study for, 770
mammography of, 862
myocardial infarction scan and, 886
plethysmography and, 950
ultrasonography and, 1129, 1159, 1164
x-ray of, 1028
Calcitonin, 256–259
Calcitonin stimulation test, 256–259
Calcium
blood, 259–263
ionized, 264–267
phosphorus and, 939
urine, 267–271
vitamin D and, 1220
Calcium and pentagastrin stimulation, 256–259
Calcium channel blocker, stress testing and, 595–597
Calcium homeostasis, 920–922
Calcium imbalance, 595–597
Calcium oxalate crystal, 911, 1196
Calcium phosphate crystals, 1078–1080
Calculus
bladder
cystoscopy for, 524–526
pelvic CT of, 433–437
blood creatinine clearance test and, 477–479
CT for, 433–437, 442–445
cystoscopy for, 524–526
gallbladder. See Cholelithiasis
pancreatic, 852–854
renal. See Renal calculi
retrograde ureteropyelography for, 1045–1048
ultrasonography for, 1153–1154
ureteral, 756–758
urethral, 1183–1185
urine creatinine clearance test and, 482–484
Calcus panel, 271–272
Campylobacter, 506–509, 507–509
c-ANCA (cytoplasmic antineutrophil cytoplasmic antibody), 102–104
Cancer. See Malignancy; site- and type-specific entries
Cancer antigens, 282–285
Cancer screening, proctosigmoidoscopy and, 985–988
Cancer staging
laparoscopic, 782–785
lymph node biopsy for, 202–205
lymphangiogram and, 818–821
mediastinoscopy for, 868–871
MRI in, 832, 851, 855
prostatic ultrasonography in,
1158–1160
PSA and, 933–995
Candida albicans, 501, 515–516
Candida spp., 917
Cannabinoid, 544–547
Capillaritis, 103–104
Capillary blood gas, 221–232
Capillary function, bleeding time, 220
Capillary puncture, 1253–1254
Capsule endoscopy, 273–276
Carbamate insecticide, 1030
Carbamazepine, 117–121, 543
Carbohydrate deficiency, ketones and,
767–770
Carbohydrate diet
apolipoprotein A and, 141–143
blood gas analysis in, 227–232
electrocardiogram and, 500
urine urea nitrogen level and,
1181–1182
Carbohydrate metabolism, 776–779
Carbon dioxide, 276–279
partial pressure of, in blood, 222, 223
in acidosis, 225
in alkalosis, 225
Carbon monoxide poisoning
blood gas analysis in, 226–232
methemoglobin and, 874
pulse oximetry and, 1018
Carbon tetrachloride toxicity, 960–962
Carbonic acid, 224
Carboxyhemoglobin, 280–282
Carcinoid syndrome
ACTH levels in, 10
aminic acid levels in, blood test for,
37–38
calcitonin stimulation test for,
257–259
fecal fat and, 606–608
vitamin A and, 1228
vitamin B12 and, 1228
Carcinoid tumor, 724–726
Carcinoma
aldolase levels in, 18–19
alpha,-antitrypsin levels in,
138–139
amylase levels in, 52–53
antithrombin III levels in, 135–136
breast biopsy for, 179–181
cancer antigen levels in, 284–285
colposcopy for, 353–355
cortisol levels in, 465–467
erthyocyte sedimentation rate and,
577–578
hemoglobin in, 374–378
immunoglobulin E level in, 734–735
iron level in, 762–764
kidney CT for, 442–445
mycobacteria culture/smear for, 488
pancreatic CT of, 429–433
platelet count in, 379–382
RBC morphology in, 393–396
thyroglobulin values in, 1087–1088
urinary calcium levels in, 268–271
vitamin B12 and, 1218–1219
WBC and differential in, 400–403
Carcinoma in situ, 182–185
Carcinomatosis
MRI for, 855–857
psuedocholinesterase level in,
1011–1012
Cardiac. See also Heart entries
Cardiac abnormality, 1136–1139
Cardiac allograft rejection, 254–255
Cardiac arrest, magnesium and, 823
Cardiac arrhythmias. See Arrhythmia(s)
Cardiac blood pool scan, 238–241
Cardiac chamber, 844–846
Cardiac chamber disorder
myocardial perfusion heart scan for,
890–893
PET scan for, 967–970
Cardiac CK-MB, 473–474
Cardiac cycle, 559
Cardiac disease. See Heart disease and specific conditions, e.g., Coronary artery disease (CAD)
Cardiac disorder(s)
blood gas analysis in, 226–232
carbon dioxide levels in, 277–279
echocardiography for, 551–554
proctosigmoidoscopy and, 986
Cardiac failure. See also Congestive heart failure
aldosterone levels in, 20–22
lactic acid levels and, 777–779
natriuretic peptides in, 254–255
protein level in, 996–998
Cardiac filling pressure, elevated, ANP in, 153
Cardiac function, 594–597
Cardiac glycosides, 595–597
Cardiac hypertrophy
blood pool imaging for, 239–241
myocardial perfusion heart scan for, 888–893
Cardiac inflammation, 254–255
Cardiac ischemia, 239–241
Cardiac markers, 1116
Cardiac muscle, 558
Cardiac muscle dysfunction, 599–601
Cardiac muscle ischemia, 843–846
Cardiac neoplasm
echocardiography for, 551–554
myocardial infarction scan and, 886
Cardiac output, decreased
exercise stress test for, 595–597
plethysmography and, 951
Cardiac pacemaker
MRA and, 829
MRI and, 833, 837, 841, 844, 848, 852, 855, 859
Cardiac plaque CT, 421
Cardiac rehabilitation, exercise stress test and, 594–597
Cardiac scoring, 421–424
Cardiac septal defect. See Septal defect
Cardiac trauma, 886
Cardiac troponin I (cTnI), 1116–1118
Cardiac troponin T (cTnT), 1116–1118
Cardiac valve. See named valve
Cardiac wall, echocardiography of, 551–554
Cardiolipin antibody, 113–115
Cardiomyopathy
coronary angiography of, 70–73
echocardiography for, 551–554
Holter monitor and, 707–709
microalbumin and, 877–879
transesophageal echocardiography of, 555–557
Cardiopulmonary function, 1018–1020
Cardiothoracic surgery, 618–619
Cardiotonic therapy, 890
Cardiovascular disease
abdominal laparoscopy and, 783
chest x-ray and, 301–303
folate deficiency and, 626
natural products affecting, 1274
Cardiovascular system
diagnostic tests for, 1238
laboratory and tests for, 1237
Carnivorous diet, 481–484
Carnosine, 39–41
Carotene, 1226
Carotid angiogram, 66–69
Carotid angiography, 66–69
Carotid artery stenosis, 551–554
Carotid Doppler ultrasonography, 551–554
Carpal tunnel syndrome
electromyography for, 566–567
electroneurography for, 571–572
vitamin B6 and, 1228
Cartilage, torn, 147–149
Cast(s), 1195, 1196
Castration, 629–631
CAT (computed axial tomography). See Computed tomography (CT)
Cat scratch fever
erthrocyte sedimentation rate and, 577–578
vitamin D and, 1220–1222
Catabolism, increased, 16–18
Cataract
A-scan ultrasonography for, 1132–1133
gonioscopy for, 676–677
nerve fiber analysis and, 896
pinhole test and, 1032
Catecholamine
blood and urine, 286–290
vanillylmandelic acid and, 1203
Catheter. See also Indwelling catheter
central venous, 301–303
Swan-Ganz, 301–303
Catheterization, urinary
for bacteria culture, 513
for urinalysis, 1198
for urine cytology, 536
Cation, 974, 979
Cat’s eye syndrome, 334
Cavernous sinuses, pituitary, CT of, 433–437
CBC. See Complete blood count (CBC)
C-cell hyperplasia, 257–259
CDC (Centers for Disease Control)
standard precautions, 1285–1287
transmission-based precautions, 1277–1279
CD4/CD8 enumeration, 291–293
CEA (carcinoembryonic antigen), 283
Celiac disease, 261–263
alkaline phosphatase levels in, 25–26
capsule endoscopy for, 274–276
copper levels in, 462–463
D-xylose tolerance test for, 547–550
fecal fat and, 606–608
gliadin antibody in, 116–117
glucose tolerance test for, 666–669
5-hydroxyindoleacetic acid level in, 724–726
intestinal biopsy for, 188–190
oxide levels in, 910–912
urinary calcium levels in, 269–271
Celiac disease (continued)
  vitamin D and, 1220–1222
Cellular dysplasia, 353–355
Centers for Disease Control (CDC)
  standard precautions, 1285–1287
  transmission-based precautions,
  1277–1279
Central nervous system (CNS)
  drug abuse and, 545
  vitamin B₁₂ and, 1217
Central nervous system disorder
  antidiuretic hormone and, 129–130
  glucose tolerance test for, 666–669
  sodium levels in, 1065–1067
  vitamin B₁₂ and, 1218–1219
Central nervous system tumor
  aldolase levels in, 18–19
  blood gas analysis in, 227–232
Central venous catheter, chest x-ray and,
  301–303
*Cephalosporium*, 515–516
Cerebral aneurysm, 837–839
Cerebral atrophy, 417–420
Cerebral edema, 417–420
Cerebral infarction
  CK and, 474–475
  CT of, 416–420
  EEG determining, 563–564
  MRI of, 836–839
  TG and, 1108–1111
Cerebral neoplasm. See Brain tumor
Cerebral trauma, 544–547
Cerebrospinal fluid (CSF)
  analysis of, 293–298
  FTA-ABS method for, 1081
  fungal culture of, 514–516
  tau protein in, 32–34
Cerebrovascular accident (CVA)
  aspartate aminotransferase levels in,
  150–152
  glucose levels in, 658–662
  PET scan for, 963–966
  visual field test for, 1215–1217
Cerebrovascular disease, Alzheimer’s dis-
ease markers in, 32–34
Certificate of Waiver (COW), 1273
Ceruloplasmin (Cp), 295–298,
  461–463
Cerumen accumulation, 906–907
Cervical biopsy, 182–185
Cervical block, 182–185
Cervical cancer
  cancer antigen levels in, 284–285
  colposcopy for, 353–355
  viral culture for, 517–519
Cervical cord lesion, 521
Cervical dysplasia, 182–185
Cervical erosion, 353–355
Cervical intraepithelial neoplasia,
  353–355
Cervical LEEP, 917
Cervical lymphadenopathy, infectious
  mononucleosis and, 742–744
Cervical pathology, 591–594
Cervical polyp, 182–185
Cervical smear, 915
Cervical spine angiography, 66–69
Cervical spine lymph node, biopsy of,
  182–185
Cervical spondylosis, 446–449
Cervical vaginal specimen, semen analy-
sis and, 1059
Cervicography, 353
Chain of custody protocol, 544–547
Chain substitution, Hgb electrophoresis,
  689–691
Chalasia
  barium swallow for, 160–162
  esophageal manometry for, 583
Chalasis, 1172–1174
Challenge test
  ACTH and, 7–12
  cortisol and, 463
Chancre
  lymph node biopsy for, 202–205
  syphilis serology testing for,
  1081–1083
Charcoal. See Activated charcoal
CHD (congenital heart disease), 844–846
Chédiak-Higashi syndrome, 380–382
Chemicals, 874–876
Chemotherapy
  abdominal laparoscopy and, 783
  bone marrow biopsy during, 174–177
  erythropoietin level and, 581
  immunofixation electrophoresis and,
  731
  immunoglobulin level with, 738
  proctosigmoidoscopy and, 986
  RBC count in, 384–388
  RBC morphology in, 393–396
  uric acid level in, 1186–1188
Chest
  echocardiography of, 551–554
  lung perfusion scan of, 804–807
  lung ventilation scan of, 807–810
  MRI of, 843–846
  myocardial perfusion heart scan of,
  888
  PET scan of, 966–970
  transesophageal echocardiography of,
  554–557
  chest lesion, CT of, 454–456
  chest mass, 805–807
  chest pain
    abdominal laparoscopy and, 783
echocardiography for, 551–554
exercise stress test for, 595–597
gynecologic laparoscopy and, 786
vertebroplasty and, 1212
Chest radiography, 301–303, 1119
Chest trauma, 1016–1017
Chest tube, chest x-ray and, 301–303
Chest wall trauma
myocardial infarction scan and, 886
prolactin level in, 991–993
Chest x-ray, 301–303, 551–554
Chiari-Frommel syndrome, 991–993
Chickenpox
syphilis serology testing for, 1081–1083
varicella-zoster and, 1205–1207
Child
acute iron poisoning, 761
age-specific communication and, 1266
amino acid screen in, 39–41
blood gas analysis in, 221–232
calcium values in, 259–260
carbon dioxide measurement in, 276
complement proteins in, 356
feminization in, 589–590
follicle-stimulating hormone level in, 628
glucose levels in, 657
growth spurt in, 904–905
haptoglobin level in, 685
hearing loss audiometry in, 156
hypoglycemia in, 745
intravenous pyelography and, 756
lymphangiography and, 819
metanephrine levels in, 871
protein level in, 996
radiography of, 1028–1029
retrograde ureteropyelography and, 1046
sodium levels in, 1065
total cholesterol level in, 329–333
total CK in, 472
uric acid level in, 1185–1188
urine urea nitrogen level in, 1181–1182
vanillylmandelic acid level in, 1203
vitamin C level in, 1227
Child abuse, 1028–1029
Chlamydia, 304, 917. See also Chlamydia trachomatis
Chlamydia group antibody, 304–306
Chlamydia psittaci, 304
Chlamydia trachomatis, 304–306, 494
DNA probe assays for, 304, 492
Chloride
blood, 306–310
sweat, 311–314
Cholangiocarcinoma
cancer antigen levels in, 284–285
percutaneous transhepatic cholangiography for, 315–318
Cholangiography
percutaneous transhepatic, 314–318
postoperative, 318–321
Cholangiopancreatography, endoscopic retrograde, 321–324
Cholangitis
bilirubin levels in, 164–166
ERCP in, 321–324
MRI for, 833–835
percutaneous transhepatic cholangiography in, 315–318
Cholecalciferol, 1220
Cholecystitis, 1148–1149
alkaline phosphatase levels in, 24–26
bilirubin levels in, 164–166
hepatobiliary scan for, 701–704
lipase levels in, 797–799
Choledochal cyst, 701–704
Cholelithiasis, 575, 1148–1149
abdominal CT of, 404–407
hepatobiliary scan for, 701–704
liver/biliary tract CT of, 412–416
percutaneous transhepatic cholangiography for, 315–318
Cholera, 603–604
Cholescintography. See Hepatobiliary scan
Cholestasis
apolipoprotein A and, 141–143
HDLC level in, 326–329
sweat chloride and, 311–314
total cholesterol level in, 330–333
vitamin E and, 1223–1224
Cholestatic drug interaction, 164–166
Cholesterol
apolipoprotein A and B, 141–143
cardiac scoring of, 421–424
HDL and LDL, 325–329
total, 329–333
Cholesterol ester storage disease, 194–197
Cholinergics
electromyography and, 566
sphincter muscle electromyography and, 568–570
Cholinesterase, red blood cell, 1030–1032
Chondromalacia
arthrogram of, 143–146
arthroscopy of, 147–149
Chordoma, 438–441
Chorea, 114
Choriocarcinoma, 715–717
Chorioepithelioma, 989–990
Chorionic gonadotropin, human, 714–717
quad-marker testing and, 613, 715
triple-marker testing and, 613, 614, 715
Chorionic villus biopsy, 185–188
Choristoma, 859–861

C. nevus
fundus photography and, 634–635
visual field test and, 1215–1217
Chromosome abnormality, 48–51
Chromosome analysis, blood, 333–336
Chronic bilateral pyelonephritis, 482–484
Chronic bronchitis
plethysmography for, 951–954
pulmonary function study for, 1016–1017
Chronic disease, 1112–1113
Chronic fatigue syndrome, infectious mononucleosis and, 742–744
Chronic glomerulonephritis, 1189
Chronic granulocytic leukemia, 1218–1219
Chronic hemolytic anemia, 393–396
Chronic hepatitis. See Hepatitis
Chronic infection
cryoglobulin detection in, 485–486
transferrin level in, 1106–1108
vitamin A and, 1228
Chronic inflammation, 795–797
Chronic inflammatory disease, 384–388
Chronic interstitial nephritis, 975–978
Chronic kidney disease (CKD)
creatinine in, 476, 480
vitamin levels and, 1227
Chronic lymphoblastic leukemia, 795–797
Chronic lymphocytic leukemia, 485–486
Chronic myelocytic leukemia, 331–333
Chronic myelogenous leukemia, 796–797
Chronic obstructive pulmonary disease (COPD)
A/a gradient and a/A ratio in, 30
aldosterone levels in, 20–22
alpha1–antitrypsin levels in, 138–139
blood gas analysis in, 226–232
erythropoietin level in, 581–582
hematocrit in, 369–372
hemoglobin in, 374–378
lung perfusion scan for, 805–807
lung ventilation scan for, 808–810
PET scan for, 967–970
plethysmography for, 951–954
pulmonary function study for, 1015–1017
RBC count in, 384–388
total cholesterol level in, 331–333
transesophageal echocardiography of, 555–557
vitamin B12 and, 1218–1219
Chronic pulmonary disease
apolipoprotein B and, 141–143
LDLC level in, 327–329
Chronic renal failure (CRF)
amino acid levels in, urine test for, 40
prealbumin and, 983–984
prolactin level in, 991–993
vitamin B12 and, 1218–1219
Chronic sinopulmonary disease, 737–738
Churg-Strauss syndrome, 103–104
Chylous pleural effusion, 956–958
Cigarette smoking. See Smoking
Ciliary body, gonioscopy of, 675–677
Cimetidine, 606
Cine scanning, 404, 412–413
Circadian rhythm
luteinizing hormone secretion and, 815
magnesium level and, 826
Circulating anticoagulant
aPTT in, 927–929
prothrombin time and, 1008–1011
Circulating C3, 356
Circulating fibrinogen
aPTT in, 927–929
rouleaux and, 577
Circulation. See Blood flow
Circulatory overload, transfusion related, 1271
Cirrhosis, 254–255
abdominal laparoscopy for, 782–785
AFP levels in, 614–617
alanine aminotransferase levels in, 13–15
aldosterone levels in, 20–22
alpha1–antitrypsin levels in, 138–139
amino acid levels in, urine test for, 40
ammonia levels in, 44–45
antimitochondrial/antismooth muscle antibody in, 101–102
antithrombin III levels in, 135–136
aspartate aminotransferase levels in, 150–152
bilirubin levels in, 164–166
calcitonin stimulation test for, 257–259
calcium values in, 261–263
cancer antigen levels in, 284–285
copper levels in, 462–463
cryoglobulin detection in, 485–486
estradiol level in, 589–590
GGT levels in, 670–672
glucagon level in, 655–657
HDLC level in, 326–329
human growth hormone levels in, 683–684
lactate dehydrogenase levels in, 775–776
liver and spleen scan for, 801–803
liver biopsy for, 194–197
osteocalcin levels and, 904–905
oxalate levels in, 910–912
percutaneous transhepatic cholangiography for, 315–318
peritoneal fluid analysis for, 936–938
platelet count in, 379–382
protein level in, 996–998
protoporphyria and, 575
pseudocholinesterase level in, 1011–1012
renin value in, 1036–1039
rheumatoid factor and, 1049–1050
total iron-binding capacity and, 765–766
triglyceride levels and, 1109–1111
ultrasonography for, 1148–1149
vitamin B12 and, 1218–1219
vitamin E and, 1223–1224
WBC and differential in, 400–403
zinc level in, 1235–1236

Citrulline, 39–41
CK (creatine kinase), 472–475
CKD (chronic kidney disease) creatinine in, 476, 480
vitamin levels and, 1227
Claustraphobia
MRA and, 829
MRI and, 837, 841, 844, 848, 852, 856, 859
Clean-catch specimen. See also Urine specimen
for drug screening, 547
for magnesium measurement, 826
for microalbumin testing, 878
for urinalysis, 1198
for urine cytology, 535
hemosiderin stain and, 692–693
ketones, measuring levels in, 769
osmolality and, 901
oxalate levels in, 911
phosphorus levels and, 944
porphyrin levels and, 960–962
potassium levels and, 981
Cleaning, isolation precautions and, 1282
CLIA (Clinical Laboratory Improvement Amendments), 1273
Clinical Laboratory Improvement Amendments (CLIA), 1273
Clomiphene, 542
Clomiphene induction, progesterone and, 988–990
Clonorchis sinensis infection, 908–909
Closing volume, 1014, 1016
Clostridium
bacterial culture for, 494–497
stool culture for, 506–509
Clostridium botulinum, 507–509
Clostridium difficile, 507–509
Clot. See Blood clot
Clot removal, venipuncture and, 1256–1257
Clot retraction test, 336–337
Clotting factor congenital deficiency, 927–929
Clotting specimen, 949
Clue cell, 1195
CMV. See Cytomegalovirus (CMV)
CNS. See Central nervous system (CNS) entries
Coagulation. See Blood clot
Coagulation defect, 587
Coagulation factors, 338–341
deficiency of
aPTT in, 927–929
vitamin B12 and, 1218–1219
Coagulopathy
bleeding time and, 220
disseminated intravascular. See Disseminated intravascular coagulation (DIC)
Coarctation, 829–831
Cobalamin abnormality, 1218–1219
Cocaine abuse, 544–547, 894–895
Cocaine dependence, 126–128
Coccidioides immitis, 515–516
Coccidioidomycosis bronchoscopy for, 250–253
calcium values in, 260–263
mediastinoscopy for, 868–871
Codocyte, 363, 392
COHb (carboxyhemoglobin), 280–282
Cold agglutinin titer, 341–343
Cold hemagglutinin disease, 341–342
hemosiderin in, 692
IgM in, 737
Cold sensitivity, RAIU and, 1021–1023
Cold spot, in thyroid scan, 1089–1092
Colitis
amebic, 603–604
colonoscopy for, 347–350
granulomatous, 157–159
ulcerative. See Ulcerative colitis
WBC and differential in, 400–403
Collagen cross-linked N-telopeptide (NTx), 344–346
Collagen disease/disorder, 577–578
copper levels in, 462–463
WBC and differential in, 399–403
Collateral circulation, 634–635
Colon. See also Colitis
barium enema of, 157–159
proctosigmoidoscopy of, 985–988
Colon cancer. See also Colorectal cancer
alkaline phosphatase levels in, 24–26
barium enema for, 157–159
colonoscopy for, 347–350
human chorionic gonadotropin level
in, 716–717
Colon perforation, 157–159
Colonic polyp
barium enema and, 157–159
colonoscopy and, 347–350, 425–429
fecal analysis and, 605–609
proctosigmoidoscopy and, 986–988
Colonography, 425
Colonoscopy, 346–350, 602
Color blindness, 351–352
Color perception test, 351–352
Colorectal adenoma, 602
Colorectal cancer. See also Colon cancer
barium enema for, 157–159
cancer antigen levels in, 284–285
FDG-PET scan for, 599–601
Coloscopy, 353–355
Coma, 545. See also Hepatic coma
acetaminophen intoxication and, 54–57
anticonvulsant toxicity and, 261–263
antidepressants toxicity, 124–128
antipsychotic toxicity, 131–134
diabetic, 544–547
lidocaine toxicity and, 86–92
Common bile duct dilation
abdominal CT of, 404–407
kidney CT for, 442–445
liver/biliary tract CT of, 412–416
Common bile duct obstruction
amylase levels in, 52–53
hepatobiliary scan for, 701–704
Common vehicle transmission of
pathogen, 1278
Communication, age-specific, 1265–1268
Compatibility test, 233
Complement protein
C3 and C4, 356–358
total, 359–360
Complete blood count (CBC), 360–367
hematocrit, 367–372
hemoglobin, 372–378
platelet count, 378–382
RBC count, 383–388
RBC indices, 363, 388–391
RBC morphology and inclusions, 391–396
white blood count and differential in, 396–403
Compound F, 463
Compression fracture, vertebroplasty
and, 1212
Computed axial tomography (CAT). See
Computed tomography (CT)
Computed tomography (CT)
angiography, 408–412
cardiac scoring, 421–424
colonoscopy, 425–429
of abdomen, 403–407
of biliary tract and liver, 412–416
of brain, 416–420
of kidney, 441–445
of pancreas, 429–433
of pelvis, 433–437
of pituitary gland, 437–441
of spine, 445–449
of spleen, 449–453
doctor, 453–456
spleen ultrasonography and, 1163
Computed tomography angiography
(CTA), 408–412
Computed transaxial tomography (CTT).
See Computed tomography (CT)
Conduction defect, Holter monitor and, 707–709
Conduction velocity, ENG and, 570–572
Conductive hearing loss, 1071–1073
Condylar injury, arthroscopy of, 146–149
Condyloma
colposcopy for, 353–355
Pap smear and, 917
Condylomata, 517–519
Cone biopsy, 182–185
Confusion
acetaminophen intoxication and, 54–57
antidepressant toxicity and, 124–128
antipsychotic toxicity and, 131–134
Congenital adrenal hyperplasia (CAH)
ACTH levels in, 10
progesterone testing for, 989–990
sweat chloride and, 311–314
Congenital anomaly
abdominal angiography of, 58–61
brain CT of, 417–420
carotid angiography of, 67–69
coronary angiography of, 70–73
echocardiography for, 551–554
electrocardiogram for, 558–561
renal angiography of, 79–82
ultrasonography for, 1145–1147
upper GI series for, 1172–1174
Congenital athyrosis, 1087–1088
Congenital biliary atresia, 701–704
Congenital cardiac septal defect, 30–32
Congenital dyserythropoietic anemia, 683
PNH and, 685
Congenital fibrinogen deficiency, 620–622
Congenital heart block, 106–108
Congenital heart defect, 226–232
Congenital heart disease
- ECG in, 558
- echocardiography in, 551
- MRI in, 844
- TEE in, 554, 555
Congenital infection, 380–382
Congenital methemoglobinemia, 874–876
Congenital nephrosis, AFP in, 615
Congenital nonspherocytic anemia
- G6PD levels in, 663
- pyruvate kinase levels in, 1020
Congenital porphyria, 960–962
Congenital renal anomaly, 771–772
- intravenous pyelography for, 756–758
- retrograde ureteropyelography for, 1045–1048
Congenital urinary tract abnormality, 756–758
Congenital venous malformation, venography of, 1207–1211
Congestive heart failure
- albumin/globulin ratio, 16–18
- alkaline phosphatase levels in, 24–26
- aspartate aminotransferase levels in, 150–152
- blood creatinine clearance test and, 477–479
- blood gas analysis in, 226–232
- BNP levels in, 237, 254
- BUN levels in, 1178–1180
- cardiac CK-MB and, 474–475
- chloride values in, 308–310
- echocardiography for, 551–554
- erythrocyte sedimentation rate and, 577–578
- hematocrit in, 369–372
- hemoglobin in, 374–378
- lactate dehydrogenase levels in, 775–776
- osmotic concentration and, 900–902
- potassium levels and, 976–978
- renin value in, 1036–1039
- sodium levels in, 1065–1067
- transesophageal echocardiography of, 555–557
- uric acid level in, 1186–1188
- vitamin B12 and, 1218–1219
Conjugated/direct bilirubin, 162–166
Conjunctiva, slit-lamp biomicroscopy of, 1061
Conjunctivitis
- slit-lamp biomicroscopy for, 1062–1064
- viral culture for, 517–519
Connective peptide insulin, 467
Connective tissue disease
- angiotensin-converting enzyme in, 82–83
- antinuclear antibody and, 106–108
- anti-ribonucleoprotein and, 106–108
- bone marrow biopsy for, 174–177
- immunoglobulin E level in, 737–738
- syphilis serology testing for, 1082–1083
Conn's syndrome, 20–22
Constrictive pericarditis, MRI of, 844–846
Contact lens, 1062–1064
Contact precautions, 1284, 1288–1289
Contact transmission of pathogen, 1277
Contraction stress test (CST), 1135
Contrast medium. See also specific agent
- for abdominal angiography, 57–61
- for adrenal angiography, 62–65
- for adrenal scintigraphy, 4–7
- for barium enema, 157–159
- for barium swallow, 160–162
- for carotid angiography, 70–73
- for coronary angiography, 70–73
- for hysterosalpingography, 727–730
- for IVP, 755–758
- for lymphangiography, 818–821
- for pulmonary angiography, 74–77
- for renal angiography, 78–82
Contusion
electroneurography and, 457–458
renogram for, 1040–1042
Convulsion
- antipsychotic toxicity, 131–134
- lidocaine toxicity and, 86–92
- magnesium toxicity and, 822–824
- salicylate intoxication and, 227–232
Coombs' antiglobulin
- direct, 457–458
- indirect, 459–460
COPD. See Chronic obstructive pulmonary disease (COPD)
Copper, 461–463, 927
Copper intoxication, 299–300
Copper oxidase, 295–298
Copper poisoning, 299–300
Copper uterine device, use, 462–463
Coproporphyrin, 959–962
Cord blood, 657
Cord blood gas, 221–232
Core biopsy, breast, 1074–1077
- ultrasonography for, 1142–1144
Cornea
- pachymetry for, 913–914
- slit-lamp biomicroscopy of, 1061
Corneal abrasion, 1062–1064
Corneal arcus, 327–329
Corneal disorder, 896
Corneal endothelial disorder, 676–677
Corneal erosion, 1062–1064
Corneal infection, 1062–1064
Corneal rejection, 913–914
Corneal thickness, 913–914
Corneal ulcer, 1062–1064
Coronary angiography, 70–73
Coronary artery calcification, 886
Coronary artery disease (CAD) angiography in, 70
apolipoprotein A and, 141–143
apolipoprotein B and, 141–143
exercise stress test for, 594–597
FDG-PET scan for, 598–601
Framingham algorithm and, 1108
HDLC and LDLC levels in, 326–329
homocysteine level and, 710–711
MRI for, 844–846
myocardial perfusion heart scan for, 888–893
tansesophageal echocardiography of, 554–557
zinc level in, 1234–1236
Coronary artery plaque, CT of, 421–424
Coronary blood flow
myocardial infarction scan and, 886
myocardial perfusion heart scan and, 888–893
Coronavirus, viral culture and, 517–519
Corpus luteum, 988–990
Corrective lens, refractive errors and, 1032–1035
Corticosteroids, 825–828
Corticotropin, 543
Corticotropin-releasing hormone (CRH) stimulation, 7–12, 464–467
Cortisol challenge tests and, 463
DHEAS and, 542
eosinophil count suppression, 573–575
Corynebacterium, 494, 509
Corynebacterium diphtheriae, 502, 509
Cosyntropin, 465
Cough bronchoscopy for, 249–253
tuberculin skin test for, 1118–1122
Cough medicine, 546
Coumarin, APTT and, 925–929
Coumarin-induced skin necrosis, protein S and, 1001–1003
COW (Certificate of Waiver), 1273
Cox’s milk, phosphorus in, 939
Coxsackievirus, 517–519
Cp (ceruloplasmin), 295–298, 461–463
C-peptide, 467–469
CPK (creatin phosphate kinase), 472–475
Cranial bone, MRI of, 836–839
Cranial tumor, 963–966
Craniosynostosis
brain CT of, 417–420
MRI for, 837–839, 859–861
pituicytoma CT of, 437–441
C-reactive protein (CRP), 470–472
Creatine kinase (CK), 472–475
Creatine phosphokinase (CPK), 472–475
Creatinine
blood, 476–479
eGFR and, 477
homovanillic acid and, 712
metanephrine and, 872
renogram and, 1040
urine, 480–484
vanillylmandelic acid and, 1203
Creatinine clearance test
blood sample and, 476–479
urine sample and, 480–484
Cretinism, ALP levels in, 23–26
Creutzfeldt-Jakob disease
Alzheimer’s disease markers and, 32–34
PET scan for, 963–966
CRF. See Chronic renal failure (CRF)
CRH (corticotropin-releasing hormone), 7–12, 464–467
Cri du chat syndrome, 334
Crigler-Najjar syndrome, 164–166
Crohn’s disease
albumin/globulin ratio, 16–18
barium enema for, 157–159
beta-2-microglobulin levels in, 880–883
capsule endoscopy for, 274–276
colonoscopy for, 347–350
CRP assay for, 470–472
eythrocyte sedimentation rate and, 577–578
fecal fat and, 606–608
folate level in, 626–628
immunoglobulin E level in, 737–738
magnesium level and, 825–828
potassium levels and, 976–978
proctosigmoidoscopy for, 985–988
protein level in, 996–998
vitamin B12 and, 1218–1219
Croup, 517–519
CRP (C-reactive protein), 470–472
Crush injury
albumin/globulin ratio, 16–18
aldolase levels in, 18–19
WBC and differential in, 400–403
Cryoglobulin, 485–486, 738
Cryoglobulinemia
complement protein levels in, 357–358, 359–360
detection of, 485–486
immunofixation electrophoresis for, 731
Cryptococcosis, 515–516
Cryptorchidism
infertility and, 109–110
testosterone and, 1085–1086
ultrasound for, 1161–1163
Cryptosporidiosis, 908–909
Cryptosporidium parvum infection, 908–909
Crystal(s)
calcium oxalate, 911, 1196
calcium phosphate, 1078–1080
cystine, 1196
hemoglobin C, 364, 392
leucine, 1196
tyrosine, 1196
urine, 1196
Crystallization, amniotic fluid, 46
CSF. See Cerebrospinal fluid (CSF)
CST (contraction stress test), 1135
CT. See Computed tomography (CT)
C-terminal parathyroid hormone, 919–922
cTNI (cardiac troponin I), 1116–1118
cTNT (cardiac troponin T), 1116–1118
Cu. See Copper
Culture
anal/genital, 492–497
blood, 498–501, 514–516
body fluid, 514–516
bone marrow, 514–516
ear, 492–497
eye, 492–497
fungal, 514–516
genital, 492–497
hair, 514–516
mycobacterial, 487–492
nail, 515–516
nasopharyngeal swab, 509–511
skin, 492–497, 514–516
sputum, 501–506, 514–516
stool, 506–509, 514–516
throat, 509–511
urine, 511–514
viral, 517–519
wound, 492–497
white blood cell scan for, 1231–1233
Curettage biopsy, 212–214
Cushing’s disease
ACTH levels in, 9–10
albumin/globulin ratio, 16–18
chloride values in, 307–310
cortisol levels in, 465–467

glucagon level in, 655–657

glucose levels in, 658–662

glucose tolerance test for, 666–669
potassium levels and, 976–978, 980–982
renin value in, 1036–1039
sodium levels in, 1065–1067
WBC and differential in, 399–403
Cushing’s syndrome, 254–255
adrenal scintiscan for, 5–7
apolipoprotein B and, 141–143
cortisol levels in, 9–10
DHEAS and, 542–543
LDLC level in, 327–329
WBC and differential in, 400–403
CVA. See Cerebrovascular accident (CVA)
Cyanocobalamin, 1217–1219
Cyanosis
methemoglobin and, 874
sputum cytology and, 530
Cyclic antidepressants, 126–128
Cyclosporine, 739–742, 825–828
Cyclotron, 970
Cyst(s)
abdominal angiography of, 58–61
abdominal CT of, 404–407
arthrogram of, 143–146
arthroscopy of, 147–149
brain CT of, 417–420
carotid angiography of, 67–69
CT angiography of, 409–412
gynecologic laparoscopy for, 786–788
hepatobiliary scan for, 701–704
intravenous pyelography for, 756–758
kidney CT for, 442–445
lipase levels in, 797–799
liver and spleen scan for, 801–803
liver/biliary tract CT of, 412–416
mammography for, 862–864
MRI for, 855–857, 858–861
pelvic CT of, 433–437
percutaneous transhepatic cholangiography for, 315–318
pituitary CT of, 437–441
progesterone testing for, 989–990
renogram for, 1040–1042
skin biopsy for, 212–214
slit-lamp biomicroscopy for, 1062–1064
splenic CT of, 450–453
thoracic CT for, 454–456
thyroid biopsy for, 215–217
thyroid scan for, 1090–1092
ultrasoundography for, 1140, 1145, 1156, 1161, 1164
Cyst aspiration, breast ultrasonography for, 1142–1144
Cystathionine, 39–41
Cystic breast disease, 1143–1147
Cystic fibrosis
  blood gas analysis in, 226–232
  copper levels in, 462–463
  fecal analysis for, 603–604
  fecal fat and, 606–608
  glucagon level in, 655–657
  5–hydroxyindoleacetic acid level in, 724–726
  sodium levels in, 1065–1067
  sweat chloride values in, 1223–1224
  vitamin A and, 1228
  vitamin K and, 1225–1226
Cystic focal disease, 800–803
Cystine, 39–41
Cystine crystals, 1196
Cystinosis
  amino acid levels in, urine test for, 40
  blood gas analysis in, 227–232
  calcium values in, 261–263
Cystitis
  cystoscopy and, 524
  ultrasonography for, 1140–1141
  viral culture for, 518–519
Cystography, 526–529, 1045
Cystometry, 520–523
Cystoscopy, 523–526
Cystourethrography, voiding, 526–529
Cytogenic markers, 219
Cytology
  of sputum, 527
  of urine, 534–536
Cytomegalovirus (CMV)
  beta2–microglobulin levels in, 881–883
  bronchoscopy for, 250–253
  IgG and IgM, 537–538
  Pap smear and, 917
  urine cytology for, 534–536
  viral culture for, 518–519
Cytoplasmic antineutrophil cytoplasmic antibody (c-ANCA), 102–104
Cytotoxic agents
  abdominal laparoscopy and, 783
  bone marrow biopsy after, 175–177
  proctosigmoidoscopy and, 986
Cytospin ThinPrep PapTest, 917

D
D antigen, 233–237
Dacryocyte, 363, 392
D-aminolevulinic acid, 41–43
Danazol, 543
DAT (direct antiglobulin testing), 457–458
D-dimer, 539–541
Depression
  anion gap for, 84–86
  blood creatinine clearance test and, 477–479
  calcium values in, 260–263
  carbon dioxide levels in, 278–279
  chloride values in, 307–310
  hematocrit in, 369–372
  hemoglobin in, 374–378
  hemoglobin levels and, 690
  hysterosalpingography and, 728
  intravenous pyelography and, 756
  lymphangiography and, 819
  magnesium level and, 822–824
  osmotic concentration and, 900–902
  potassium levels and, 975–978
  protein level in, 996–998
  renogram and, 1040
  retrograde ureteropyelography and, 1046
  sodium levels in, 1065–1067
  transesophageal echocardiography and, 555
  ultrasonography and, 1137, 1140, 1151, 1156–1158, 1164
  uterine fibroid embolization and, 1200
  venogram and, 1208
  voiding cystourethrography and, 527
Dehydroepiandrosterone sulfate (DHEAS), 541–543
Delayed immune-mediated transfusion reaction, 1271
Delirium tremens
  aspartate aminotransferase levels in, 150–152
  skeletal muscle CK-MM and, 474–475
Delta bilirubin, 162–166
Delta hepatitis, 700
Delta globulin, 996–998
Dementia
- Alzheimer’s disease and, 32–34
- markers for, 32–34
- evoked brain potentials in, 591–594
- FDG-PET scan for, 598–601
- PET scan for, 963–966

Deoxygenated hemoglobin, 874

Deoxyribonucleic acid. See DNA entries

Depolarization, 558

Depression, 126–128
- ACTH levels in, 10
- antipsychotic/antimanic drugs for, 131–134
- 5-hydroxyindoleacetic acid level in, 725–726

Depression of respiratory center, 226–232

Dermatitis
- atopic, 27–28
- eosinophil count in, 573–575
- exfoliative, 626–628
- immunoglobulin E level in, 734–735
- skin biopsy for, 212–214

Dermatitis herpetiformis, 116–117

Dermatofibroma, 212–214

Dermatomyositis
- aldolase levels in, 18–19
- aspartate aminotransferase levels in, 150–152
- complement protein levels in, 357–358
- electromyography for, 566–567
- Jo-1 antibody and, 106–108
- rheumatoid factor and, 1049–1050
- skeletal muscle CK-MM and, 474–475

DES (diethylstilbestrol), 353

Desipramine, 124–128

DEXA (dual-energy x-ray absorptiometry), 242–245

Dexamethasone, 543

Dexamethasone suppression test (DST), 7–12, 464–467

DHEAS (dehydroepiandrosterone sulfate), 541–543

DIA (dimeric inhibin-A), 614

Diabetes
- antidiuretic hormone and, 129–130
- chloride values in, 307–310, 311–314
- osmolality and, 899–902

Diabetes mellitus. See also Diabetic entries
- ACTH levels in, 10
- aldosterone levels in, 20–22
- alkaline phosphatase levels in, 24–26
- amino acid levels in, blood test for, 37–38
- apolipoprotein A and, 141–143
- apolipoprotein B and, 141–143
- cardiac scoring for, 421–424

cause and effects of, 658
- complement protein levels in, 357–358
- C-peptide levels in, 468–469
- fecal fat and, 606–608
- fluorescein angiography in, 623
- fructosamine level in, 632–633
- fundus photography in, 633
- gastric emptying scan for, 643–645
- GGT levels in, 670–672
- glucagon level in, 655–657
- glucose tolerance test for, 665–669
- glycated hemoglobin AIC and, 672–674
- HDLC and LDLC levels in, 326–329
- hexosaminidase level in, 705–706
- human growth hormone levels in, 683–684
- hyperlipoproteinemia and, 799–800
- insulin antibody and, 748–749
- insulin levels in, 745–747
- insulin-dependent (type 1)
  - C-peptide levels in, 468
  - insulin levels in, 745
  - intrinsic factor antibody and, 759
- insulin-resistant, 745
- intrinsic factor antibody and, 759–760
- ketone level in, 767–770
- lactic acid levels and, 777–779
- lecithin/sphingomyelin ratio in, 792–795
- microalbumin and, 877–879
- non-insulin-dependent (type 2)
  - C-peptide levels in, 468
  - insulin levels in, 745
- oxalate levels in, 910–912
- pseudocholinesterase level in, 1011–1012
- sodium levels and, 1068–1071
- sodium levels in, 1065–1067
- total cholesterol level in, 330–333
- type 1 (insulin-dependent)
  - C-peptide levels in, 468
  - insulin levels in, 745
  - intrinsic factor antibody and, 759
- type 2 (non-insulin-dependent)
  - C-peptide levels in, 468
  - insulin levels in, 745
- uric acid level in, 1186–1188
- urinary calcium levels in, 268–271
- urine urea nitrogen level in, 1180–1182
- visual field test for, 1215–1217
- vitamin B₆ and, 1228
- vitamin B₁₂ and, 1218–1219
- zinc level in, 1235–1236
Diabetic acidosis. See also Diabetic ketoacidosis
catecholamine levels in, 287–290
magnesium level and, 822–824
Diabetic coma, 544–547
Diabetic diet, 661
Diabetic glomerulosclerosis, 1189
Diabetic ketoacidosis
blood gas analysis in, 227–232
carbon dioxide levels in, 278–279
chloride values in, 308–310
osmotic concentration and, 900–902
phosphorus levels in, 939–942
potassium levels and, 980–982
WBC and differential in, 400–403
Diabetic ketosis
amino acid levels in, urine test for, 40
amylase levels in, 52–53
Diabetic nephropathy
microalbumin and, 877–879
protein levels in, 1004–1006
Diabetic neuropathy
anticonvulsants for, 119–121
electromyography in, 566–567
electroneurography for, 571–572
Diabetic retinopathy
fluorescein angiography for, 623
fundus photography for, 634–635
Diagnostic tests
for auditory system, 1237
for cardiovascular system, 1238
for endocrine system, 1239
for gastrointestinal system, 1240
for genitourinary system, 1241
for hematopoietic system, 1242
for hepatobiliary system, 1243–1244
for immune system, 1245
for musculoskeletal system, 1246
for ocular system, 1247
for reproductive system, 1248
for respiratory system, 1249
nursing diagnoses associated with, 1264
patient preparation for, 1251, 1263
Dialysis
potassium levels and, 975–978
vitamin B₆ and, 1228
Diaphoresis, acetaminophen intoxication and, 54–57
Diaphragm, flattened, 302–303
Diaphragmatic hernia, chest x-ray and, 301–303
Diaphragmatic inflammation, 801–803
Diarrhea
blood gas analysis in, 227–232
carbon dioxide levels in, 278–279
chloride loss in, 308
colonoscopy in, 347–350
illness with, ketones and, 767–770
magnesium level and, 823–824
phosphorus levels in, 940–942
potassium levels and, 976–978
radioactive iodine uptake and, 1022
sodium levels in, 1065–1067
thyroid scan and, 1090
vitamin K and, 1225–1226
Dibucaine number, 1011–1012
DIC. See Disseminated intravascular coagulation (DIC)
Diet
fecal analysis and, 603
gastric acid stimulation test and, 640–642
hepatobiliary scan and, 702
5–hydroxyindoleacetic acid level and, 725
parathyroid scan and, 923
potassium levels and, 975–978
radioactive iodine uptake and, 1022
renin value and, 1037
thyroid scan and, 1090
urinalysis and, 1196
urine urea nitrogen level and, 1181–1182
vitamin B₁₂ and, 1218–1219
vitamin levels and, 1229
Dietary protein, urea nitrogen and, 1180–1182
Dietary purine, 1186–1188, 1189–1191
Diethylstilbestrol (DES), 353
Differentiated thyroid cancer, 1087–1088
Diffusing capacity, 1012–1017
Diffusing capacity of lungs (DCOL), 1015–1017
DiGeorge syndrome, 921–922
Digestive enzyme deficiency, 606–608
Digibind (digoxin immune Fab), 89
Digital rectal examination, 993
Digitalis, 560
Digoxin, 86–92
Digoxin immune Fab (Digibind), 89
1,25–Dihydroxy vitamin D. See Vitamin D
Dimeric inhibin-A (DIA), 614
Diphertheria, 501
Diptheroid, 501
Diphyllobothrium infection, 908–909
Dipstick urinalysis, 1192–1199
Dipyridamole, blood pool imaging, 237–241
Direct antiglobulin testing (DAT), 457–458
Direct contact transmission of pathogen, 1277
Direct platelet-bound IgG/IgM, 948–949
Direct strep screen, 680–681
Discoid lupus erythematosus, 212–214
Disease transmission, isolation precautions, 1277–1284
Disk herniation, 446–449, 571–572
electromyography for, 565–567
MRI for, 848–850
Dislocation(s), 147
arthroscopy in, 147
bone scan for, 246
x-ray of, 1028
Disopyramide, 86–92
Displaced lens, 676–677
Disseminated carcinoma, 1087–1088
Disseminated intravascular coagulation (DIC)
aPTT in, 927–929
D-dimer in, 539
factors in, 339–341
plasminogen levels in, 946–947
platelet count in, 380–382
protein C levels in, 1001–1003
prothrombin time and, 1008–1011
Disseminated lupus erythematosus, 191–194, 400–403
Disseminated tuberculosis, 1228
Distended bladder, 1232
Diuretic(s)
yellow casts and, 1196
lithium and, 133–134
magnesium level and, 825–828
urine potassium and, 980
Diuretic abuse
aldosterone levels in, 20–22
phosphorus levels and, 943–945
sodium levels and, 1065–1067
Diuretic therapy
potassium levels and, 980–982
sodium levels and, 1068–1071
Diurnal variation
phosphorus levels and, 940–941
prolactin and, 992
sodium levels and, 1069
transferrin level and, 1106–1108
Divertica
barium swallow for, 160–162
bronchoscopic for, 250
capsule endoscopy for, 274–276
colonoscopy for, 347–350
cystoscopy for, 524
EGD and, 587
Meckel’s, scan for, 865–867
proctosigmoidoscopy for, 985–988
retrograde urethrogramy for, 1183–1185
ultrasoundography for, 1140–1141
upper GI series for, 1172–1174
voiding cystourethrography for, 527–529
Diverticular disease
barium enema for, 157–159
capsule endoscopy for, 274–276
esophagastroduodenoscopy for, 586–589
fetal analysis for, 603–604
Diverticulosis, 651–654
Dizziness
Holter monitoring in, 707–709
magnesium toxicity and, 882–824
methemoglobin and, 874
salicylate intoxication and, 227–232
DLE (discoid lupus erythematosus), 212–214
DNA ploidy, in breast cancer, 177, 178
DNA synthesis, 1217
DNase (deoxyribonucleic acid) antibody, 122–124
Dohle body, 366
Dopamine, 286–290, 712
Doppler echo, 551–554
Doppler flow study, 950, 1168–1169
Doppler ultrasonography
arterial
barium studies with, 1126–1128
effect on EEG, 563
cardiac, 551–557
venous, extremity studies with, 1168–1171
Double contrast barium enema, 602
Double-stranded DNA herpesvirus, 1206
Down’s syndrome, 334
AFP levels in, 613–617
LAP levels in, 795–797
testosterone and, 1085–1086
uric acid level in, 1186–1188
Doxepin, 124–128
Drepanocyte, 364, 392
Dressler’s syndrome, 932–934
Droplet precautions, 1283–1284, 1288
Droplet transmission of pathogen, 1278
Drowning, near
blood gas analysis in, 226–232
potential levels and, 975–978
Drug(s)
acquired methemoglobinemia and, 874–875
aPTT and, 927
beta– microglobulin and, 881
BUN level and, 1178–1179
cholinesterase enzyme and, 1031
D-xylose level and, 547–550
effect on EEG, 563
eosinophil count and, 573–575
erthrocyte protoporphyrin levels and, 576–577
Drug(s) (continued)

erthrocyte sedimentation rate and, 577–578
erthropoietin level and, 581
exercise stress test and, 595–597
FDG-PET scan imaging and, 599
fecal analysis and, 603
fibrin degradation product and, 618–619
fibrinogen level and, 621
folate levels and, 627
follicle-stimulating hormone levels and, 630
free thyroxine level and, 1100–1101
free triiodothyronine levels and, 1112–1113
fructosamine level and, 632
gallium scan and, 637
gastric acid stimulation test and, 640–642
gastric emptying scan and, 643
gastrin levels in, 645–647
GGT levels and, 670
glucose levels and, 660
glucose tolerance test and, 666–669
glycated hemoglobin A1C and, 673
haptoglobin level and, 686–687
homocysteine level and, 710–711
homovanillic acid and, 712–713
human chorionic gonadotropin and, 716
human growth hormone and, 683
5-hydroxyindoleacetic acid level and, 725
immunoglobulin E level and, 734
immunoglobin level with, 738
immunoglobulin levels and, 731
insulin levels and, 745–747
iron level and, 762
ketone levels and, 768
lactic acid levels and, 777
LAP levels and, 796
lipase levels and, 798
lupus anticoagulant antibody and, 811
luteinizing hormone secretion and, 815
magnesium level and, 823, 826
metanephrine and, 872
methemoglobinemia and, 874–876
muscle abnormality and, 566–567
myocardial perfusion heart scan and, 890
osmotic concentration and, 900
oxalate levels and, 911
parathyroid hormone and, 921–922
PET scan and, 964, 967, 971
phosphorus levels and, 940–941, 943
plasminogen levels and, 946
platelet antibody and, 948–949
porphyrin levels and, 960–962
potassium levels and, 976–977, 980
progesterone and, 989–990
prolactin and, 991–992
protein C levels and, 999, 1002
protein level and, 997, 1004–1005
prothrombin time and, 1009
PSA levels and, 994
pulmonary function study and, 1016
radioactive iodine uptake and, 1022
renin value and, 1036–1037
renogram and, 1040
reticulocyte count and, 1043–1044
semen analysis and, 1058
sickle cell screen and, 1060
stool analysis and, 908
TBG level and, 1098
testosterone and, 1085–1086
thyroglobulin values and, 1087–1088
thyroid scan and, 1090
total iron-binding capacity and, 765
total thyroxine level and, 1103
total triiodothyronine levels and, 1115–1116
transferrin level and, 1106–1108
triglyceride levels and, 1110–1111
uric acid level and, 1187–1188
urinary nitrogen level and, 1181–1182
vanillylmandelic acid level and, 1203
vitamin B12 and, 1218
vitamin D and, 1221
vitamin E and, 1223
vitamin K and, 1225–1226
vitamin levels and, 1228–1229
zinc level and, 1235–1236

Drug abuse
intravenous, syphilis serology testing for, 1082–1083
types of, 544–547

Drug dependence, 126–128
Drug overdose, 544–547
Drug reaction
cardiolipin antibody in, 114
eosinophil count in, 573–575
Drug regimen, pulse oximetry and, 1018–1020
Drug therapy
monitoring and toxicology, laboratory tests for, 1249–1250
urinalysis for, 1193

Drug toxicity
platelet count in, 380–382
WBC and differential in, 400–403
Drug-induced anemia, 457–458
Drug-induced lupus erythematosus, 106–108
Drusen, macular, 1215–1217
Dry eye syndrome
  Schirmer tear test for, 1055–1056
  slit-lamp biomicroscopy for, 1062–1064
DST (dexamethasone suppression test), 7–12, 464–467
Dual-energy x-ray absorptiometry (DEXA, DXA), 242–245
Dubin-Johnson syndrome, 164–166
Duchenne's muscular dystrophy
  aldolase levels in, 18–19
  muscle biopsy for, 205–208
  pyruvate kinase levels in, 1020
Ductal carcinoma, 1143–1147
Dumping syndrome, 642–645
Duodenal cancer
  capsule endoscopy for, 274–276
  upper GI series for, 1172–1174
Duodenal diverticula, UGI series and, 1172–1174
Duodenal obstruction, 52–53
Duodenal papilla tumor, 321–324
Duodenal ulcer
  capsule endoscopy for, 274–276
  esophagogastro-duodenoscopy for, 586–589
  gastric acid stimulation test and, 639–642
  gastric emptying scan for, 642–645
  gastrin stimulation test for, 645–647
Duodenitis
  capsule endoscopy for, 274–276
  esophagogastro-duodenoscopy for, 586–589
Duodenum
  capsule endoscopy of, 274–276
  esophagogastro-duodenoscopy of, 586–589
Duplicated kidney, ultrasonography of, 1144–1147
DVT. See Deep venous thrombosis (DVT)
Dwarfism, 682–684
DXA (dual-energy x-ray absorptiometry), 242–245
D-xylene tolerance test, 547–550
Dye(s)
  allergic reaction to, 624
  iohinated
    angiography and, 59, 63, 67, 71, 74, 79
    hysterosalpingography and, 728
    intravenous pyelography and, 756
    voiding cystouretrography and, 527
Dyostosis, 1028–1029
Dysautonomia, catecholamines and, 287–290
Dyscrasia
  RBC count and, 384
  RBC indices and, 389
  RBC morphology and inclusions, 393
  WBC count and, 399
Dyserythropoietic anemia, 683
PNH and, 685
Dysfibrinogenemia
  fibrinogen level in, 620–622
  prothrombin time and, 1008–1011
Dysgammaglobulinemia, 799–800
Dysglobulinemia
  apolipoprotein B and, 141–143
  LDLc level in, 327–329
Dyskinesia, 239–241
Dyspepsia, 586–589
Dysphagia
  esophageal manometry for, 583
  esophagogastro-duodenoscopy for, 586–589
Dysplasia, 79–82
  abdominal angiography of, 58–61
  carotid angiography of, 67–69
  radiography for, 1028–1029
Dyspnea, 1015–1017
Dysproteinemia, 462–463
Dysrhythmia
  abdominal laparoscopy and, 783
  exercise stress test for, 595–597
  transesophageal echocardiography and, 555
Dysuria, bladder ultrasonography and, 1139–1141

E
E2 (estradiol), 589–590
Ear
  audiometry and, 153–156
  bacterial culture of, 492–497
  otoscopy of, 905–907
  tuning fork test of, 1122–1125
Ear canal, obstruction of, 906–907
Ear culture, 492–497
Ear injury, otoscopy for, 905–907
Ear pain, 905–907
Earlobe, pulse oximetry of, 1018–1020
Eating disorders, 126–128. See also Anorexia nervosa
Eaton-Lambert syndrome, 566–567
Ebola virus, 518–519
EBP (evoked brain potential), 590–594
EBV. See Epstein-Barr virus
EBV-specific serology, in infectious mononucleosis, 742–744. See also Infectious mononucleosis
Ecchymosis, bleeding time, 220
ECG (electrocardiography), 557–561
Echinococcus infection, 27–28
Echocardiography
  of heart, 551–554
  transesophageal, 554–557
Echovirus, 517–519
Eclampsia
eosinophil count in, 573–575
fibrinogen level in, 620–622
ketone level in, 767–770
uric acid level in, 1186–1188
WBC and differential in, 400–403
Ectopic ACTH-producing tumor, 9–10, 465, 542–543
Ectopic ADH-producing tumor, 129
Ectopic gastric mucosa scan, 864–867
Ectopic HCG-producing tumor, 716
Ectopic kidney, 1145–1147
Ectopic pregnancy
  amylase levels in, 52–53
  gynecologic laparoscopy for, 786–788
pelvic CT of, 433–437
ultrasonography for, 1136–1139, 1156–1158
Ectopic prolactin-secreting tumor, 991–993
Ectopic secretion, calcitonin stimulation test for, 257–259
Ectopic spleen, 1164–1166
Ectopic TSH-producing tumor, 1093–1095
Ectropion, 1062–1064
Eczema
eosinophil count in, 573–575
immunoglobulin E level in, 734–735
immunoglobulin levels in, 27–28
Edema
  brain CT of, 417–420
  pulmonary. See Pulmonary edema
  retinal, 623–625
  skeletal muscle CK-MM and, 474–475
  sweat chloride values in, 312–314
  venogram and, 1208
Edwards’ syndrome, 334
AFP levels in, 615–617
EEG (electroencephalography), 562–564
Effusion
  joint, radiography for, 1028–1029
  pericardial
    chest x-ray for, 302–303
    echocardiography for, 551–557
    MRI for, 844–846
  peritoneal, 936–938
  pleural, 956–958
  blood gas analysis in, 226–232
  chest x-ray for, 302–303
  MRI for, 843–846
  pleural fluid analysis and, 956–958
  thoracic CT for, 454–456
  pulmonary, perfusion and ventilation scans in, 804, 808
  skeletal x-ray of, 1028
  synovial, 1078
EGD (esophagogastroduodenoscopy), 190, 586–589
eGFR (estimated glomerular filtration rate), 477
Ejaculatory obstruction, 1058–1059
EKG (electrocardiography), 557–561
Elbow, MRI of, 847
Elderly adult, 542–543
  age-specific communication with, 1265–1268
  angiography in, 59, 63, 67, 71, 75, 79
  Electrocardiography (ECG), 557–561
  Electrodiagnostic study, 568–570
  Electroencephalography, 562–564
  Electrolyte balance, 1068
  Electrolyte disturbance/imbalance
    blood gas analysis in, 226–232
    carbon dioxide levels in, 277–279
    electrocardiogram and, 560
    electrocardiogram for, 559–561
    magnesium and, 825
  Electromyography (EMG), 565–567
  cystometry and, 520
  pelvic floor sphincter, 568–570
  Electroneurography (ENG), 565, 570–572
  Electrophoresis, 1003
  EM (esophageal manometry), 582–585
  EMA (endomysial antibody), 115–117
Embolism (embolus)
  angiography of, 58, 62, 78
  arterial, 950–954
  CT angiography of, 408–412
  D-dimer and, 539
  erythrocyte sedimentation rate and, 577–578
  fibrin degradation product and, 618–619
  lactic acid levels and, 777–779
  lung perfusion scan for, 805–807
  occlusion from, ultrasonography in, 1129–1131
  plethysmography of, 950
  pulmonary. See Pulmonary embolism
  renal artery, 1039–1042
  skeletal muscle CK-MM and, 474–475
  thoracic CT for, 454–456
  transfusion reaction and, 1271
  venography of, 1208
Embolization, uterine fibroid, 1199–1202
Embryonal gonadal teratoblastoma, 614–617
Emesis. See Vomiting
EMG (electromyography), 565–567
cystometry and, 520
pelvic floor sphincter, 568–570
Emphysema
blood gas analysis in, 226–232
carbon dioxide levels in, 277–279
lung perfusion scan for, 805–807
lung ventilation scan for, 808–810
plethysmography for, 951–954
pulmonary angiography of, 74
pulmonary function study for, 1016–1017
Empty sella, 859–861
pituitary CT of, 438
Empyema, 956–958
pleural fluid analysis and, 956
subdural, 837–839
ENA (antie extractable nuclear antigen), 104–108
Encephalitis
cerebrospinal fluid analysis for, 295–298
EEG determining, 563–564
mumps and, 883
Encephalopathy, lead, 790
Endarterectomy, 562
Endocarditis
antistreptolysin O antibody in, 110–111
bacterial culture for, 500–501
cryoglobulin detection in, 485–486
echocardiography for, 551–554
erythrocyte sedimentation rate and, 577–578
mitral valve, cardiolipin antibodies and, 114
RBC count in, 385–388
VDRL testing and, 1081
Endocardium, 558
Endocervical carcinoma in situ, 916
Endocrine disorder
natural products affecting, 1274–1275
sodium levels and, 1068–1071
Endocrine system
diagnostic tests for, 1239
laboratory tests for, 1238–1239
Endoluminal wall, abnormal, 426–429
Endometrial carcinoma, 284–285
Endometrioma, 1156–1158
Endometriosis
cancer antigen levels in, 284–285
gynecologic laparoscopy for, 786–788
Pap smear and, 917
Endomysial antibody, 115–117
Endomysial antibody (EMA), 115–117
Endoscope, 586
Endoscopic retrograde cholangiopancreaticography (ERCP), 321–324, 798
Endoscopy
capsule, 273–276
esophagogastroduodenoscopy, 190, 586–589
for gastrointestinal bleeding, 651–654
lower, 346–350
Endotracheal tube, chest x-ray and, 301–303
End-stage liver disease, 1110–1111
End-stage renal disease, ultrasonography of, 1145–1147
Enema, barium, 157–159
ENG (electroneurography), 565, 570–572
Entamoeba histolytica infection, 908–909
Enteritis
capsule endoscopy in, 273
fecal fat and, 606–608
folate level in, 627–628
prothrombin time and, 1009–1011
Enterobiasis, 908–909
Enterobius vermicularis infection, 908–909
Enterocolitis, fecal analysis for, 602–604
Enterogastric reflux, hepatobiliary scan for, 701–704
Enteropathy(ies)
A/G ratios in, 16
gluten-induced, 547–550
protein-losing, 997
Enterovirus, 517–519
Entropion, 1062–1064
Enuresis, 126–128
Environmental temperature, plethysmography and, 952
Enzyme(s). See specific enzyme
Enzyme abnormality
amniotic fluid analysis for, 48–51
bilirubin levels in, 164–166
Enzyme deficiency
apolipoprotein A and B, 141–143
glucose levels in, 659–662
protoporphyria and, 575
Enzyme precursor, 338
Enzyme/cofactor deficiency, 326–329
Eosinophil count, 572–575
Eosinophil cell, 398
Eosinophilic gastroenteritis, 547–550
Epicardium, 558
Epidermophyton, 515–516
 Epididymal cyst, 1162–1163
 Epididymitis, 1161–1163
 Epidural block, 182–185
 Epidural hematoma, 417–420
 Epigastric pain
esophagogastroduodenoscopy for, 586–589
pancreatic CT in, 430
Epigastric pain (continued)
upper GI series for, 1172–1174

Epilepsy
- amino acid levels in, urine test for, 40
- anticonvulsants for, 119–121
- cardiolipin antibody in, 114
- FDG-PET scan for, 599–601

Epinephrine, 286–290
- homovanillic acid and, 712
- vanillylmandelic acid and, 1203

Epistaxis, 926–929

Epithelial cell abnormality, 915

EPO (erythropoietin), 580–582

Epstein-Barr virus (EBV)
- and infectious mononucleosis, 742–744. See also Infectious mononucleosis
- culture for, 517–519
- Lyme antibody and, 816

Equilibrium phase, 808

ER (estrogen receptor) assays, in breast cancer, 177, 178

ERCP (endoscopic retrograde cholangiopancreatography), 321–324, 798

Ergocalciferol, 1220

Erythema infectiosum (fifth disease), 929–931

Erythema migrans, Lyme disease and, 816

Erythroblastosis fetalis
- bilirubin levels in, 163–166
- human chorionic gonadotropin level in, 716–717

Erythrocyte(s). See Red blood cell entries

Erythrocyte protoporphyrin test, free, 575–577

Erythrocyte sedimentation rate (ESR), 577–580

Erythrocytosis
- hematocrit in, 369–372
- hemoglobin in, 374–378

Erythroleukemia, 690

Erythropoiesis
- iron role in, 761, 764
- regulation of, 580

Erythropoietic protoporphyrin, 576–577

Erythropoietin (EPO), 580–582

ESBL (extended spectrum beta lactamase), 512–514

Escherichia coli
- bacterial culture for, 494–497
- stool culture for, 506–509
- urine culture for, 512–514

Esophageal diverticulum
- EGD and, 587
- UGI series and, 1172

Esophageal function test, 582

Esophageal manometry (EM), 582–585

Esophageal motility study, 582

Esophageal motor disorders
- gastric emptying scan and, 643
- GER scan and, 649

Esophageal mucosa, 586–589

Esophageal perforation/rupture, 587, 956–958
- barium swallow and, 160
- capsule endoscopy in, 274
- pleural fluid analysis and, 956
- upper GI series and, 1172

Esophageal scleroderma, 583

Esophageal stenosis
- capsule endoscopy for, 274–276
- esophagogastroduodenoscopy for, 586

Esophageal stricture
- EGD for, 586
- UGI series and, 1172

Esophageal ulcer, 160–162

Esophageal varices
- capsule endoscopy for, 274–276
- esophagogastroduodenoscopy for, 586–589
- fecal analysis for, 603–604

Esophageal x-ray, 160–162

Esophagitis
- barium swallow for, 160–162
- capsule endoscopy for, 274–276
- esophagogastroduodenoscopy for, 583
- esophagogastroduodenoscopy for, 586–589
- fecal analysis for, 603–604

Esophagogastroduodenoscopy (EGD), 190, 586–589

Esophagus
- barium swallow study of, 160–162
- capsule endoscopy of, 273–276
- esophagogastroduodenoscopy of, 586–589
- gastric emptying scan of, 642–645
- manometry of, 582–585
- thoracic CT for, 454–456
- upper GI series of, 1171

ESR (erythrocyte sedimentation rate), 577–580

Essential hypertension
- renin and, 1036

Essential thrombocythemia, 379–382

Estimated glomerular filtration rate (eGFR), 477

Estriol (E2), 589–590

Estriol, in triple-marker testing, 715
INDEX
Factor VIII, 1008
Factor VIII:C, 338, 1008
Factor IX, 338, 1008
Factor X, 338
Factor XI, 338
Factor XII, 338, 1008
Factor XIII, 338
Fallopian tubes
  gynecologic laparoscopy of, 785–788
  hysterosalpingography of, 727
False passages, retrograde urethrography, 1045–1048
Familial cholestasis, sweat chloride and, 311–314
Familial enzyme and lipoprotein deficiency, 140–143
Familial hyperlipoproteinemia, 141–143
Familial hyperphosphatemia, 24–26
Familial immunodeficiency disorder, 734–735
Familial periodic paralysis, 976–978
Fanconi's syndrome
  amino acid levels in, urine test for, 40
  blood gas analysis in, 227–232
  platelet count in, 380–382
  protein levels in, 1004–1006
  uric acid level in, 1187–1188, 1189–1191
  urinary calcium levels in, 268–271
Farsightedness, 1032–1035
Fasciola hepatica infection, 908–909
Fasciolopsis buski infection, 908–909
Fasting
  hepatobiliary scan and, 702
  ketone level in, 767–770
Fasting blood sugar (FBS), 657
Fat
  cortisol and, 464
  ketone bodies and, 767
Fat accumulation, 855–857
Fat malabsorption
  aPTT in, 926–929
  prothrombin time and, 1008–1011
  vitamin K and, 1225–1226
Fatigue
  methemoglobin and, 874–876
  tuberculin skin test for, 1118–1122
Fatty acid
  fecal fat and, 605–608
  oxidation of, 1222–1224
  triglycerides and, 1108–1111
Fatty diet
  apolipoprotein A and, 141–143
  fecal fat and, 607
  HDLC and LDLC levels in, 327–329
  ketone level in, 767–770
  rheumatoid factor and, 1049–1050
  total cholesterol level in, 330–333
Fatty infiltration, pancreatic, MRI of, 851–854
Fatty liver
  alanine aminotransferase levels in, 13–15
  aspartate aminotransferase levels in, 150–152
  CT of, 413
  FBP (fibrin breakdown product), 617–619
  FBS (fasting blood sugar), 657. See also Glucose
  FDG (fluorodeoxyglucose), 598
  FDG-PET scan, 598–601
  FDP (fibrin degradation product), 617–619
  Fe. See Iron (Fe)
  Febrile nonhemolytic transfusion reaction, 1270
Feces, 602–604
  abdominal laparoscopy and, 783
  analysis of, 602–604
  appearance of, 603
  blood in, 603
  barium enema and, 157
  colonoscopy for, 347
  CT colonoscopy for, 426
  proctosigmoidoscopy for, 985
  collection of, 1263
  color of, 603
  culture of, 506–509, 514–516
  fat in, 605–608
  gynecologic laparoscopy and, 786
  hysterosalpingography and, 728
  intravenous pyelography and, 756
  lymphangiography and, 819
  ova and parasites in, 603–604, 908–909
  retrograde ureteropyelography and, 1046
  ultrasonography and, 1150, 1153, 1156, 1159, 1164
  uterine fibroid embolization and, 1200
  vertebroplasty and, 1212
  vitamin D and, 1220–1221
Felty’s syndrome
  antineutrophilic cytoplasmic antibodies in, 103–104
  beta-2-microglobulin levels in, 880–883
  WBC and differential in, 400–403
Female. See Woman
Feminization, 589–590
Femoral head, MRI of, 847–850
FEP (free erythrocyte protoporphyrin), 575–577
Fern test, 46
Fever. See also specific types, e.g., Rheumatic fever
acetylsalicylic acid for, 54
acetaminophen/acetysalicylic acid for, 54
albumin/globulin ratio, 16–18
amino acid levels in, blood test for, 37–38
blood culture for, 498, 500
blood gas analysis in, 226–232
carbon dioxide levels in, 278–279
cytoplasmic casts in, 1196
cardiac disease and, 742–744
Lyme disease and, 816
nonhemolytic transfusion reaction and, 1270
of unknown origin
gallium scan for, 636–638
white blood cell scan for, 1231–1233
sodium levels and, 1065–1067
urine porphyrins and, 960
viral culture for, 517
white blood cell scan for, 1231–1233
fFN (fetal fibronectin), 611–612
FHR (fetal heart rate), 1134–1139
Fiberoptic bronchoscopy, 252
Fibrin
APTT and, 925–929
plasminogen and, 945–947
Fibrin breakdown product (FBP), 617–619
Fibrin clot, 1007–1011
Fibrin degradation product, 617–619
Fibrin split product (FSP), 617–619
Fibrinogen, 620–622
circulating, 577
clot retraction and, 336
degradation of, 927
Fibrinogen disorder, 220
Fibrinolyis
D-dimer and, 539
fibrinogen level in, 620–622
Fibrinolytic therapy, 946–947
Fibroadenolipoma, 1143–1147
Fibroadenoma, 1143–1147
Fibroid
hydrosalpinges, 728–730
gynecologic laparoscopy for, 786–788
hysterosalpingography for, 728–730
MRI for, 855–857
pelvic CT of, 433–437
ultrasonography for, 1156–1158
Fibroid embolization, 1199–1202
Fibroma, skin biopsy for, 212–214
Fibroinectin, fetal, 611–612
Fibrosarcoma
urine porphyrins and, 960
Fibrosis
breast, ultrasonography for, 1143–1147
cystic. See Cystic fibrosis
pancreatic, ERCP in, 321
plethysmography for, 951–954
pulmonary. See Pulmonary fibrosis
thyroid scan for, 1090–1092
Fifth disease (erythema infectiosum), 929–931
Filter paper test, 1095
Fine-needle aspiration biopsy
bone marrow biopsy for, 174–177
breast ultrasonography for, 1142–1147
pancreatic ultrasonography for, 1152–1154
parathyroid ultrasonography for, 1166–1168
prostatic ultrasonography for, 1158–1160
scrotal ultrasonography for, 1161–1163
Finger, venipuncture of, 1253–1254
Fingertip, pulse oximetry, 1018–1020
First morning urine. See Urine specimen
FISH (fluorescence in situ hybridization)
in bladder cancer, 218
in breast cancer, 177, 178
Flaxseed
Flavivirus, 517–519
Flexicin, 86–92
Flexible bronchoscopy, 249–253
Flexible fiberoptic endoscope, for proctosigmoidoscopy, 985–988
Flexible fiberoptic sigmoidoscopy, 985–988
Flexible proctosigmoidoscopy, 985–988
Flexible sigmoidoscopy, 602
Flow-volume loop, 1012–1017
Fluid balance/imbalance
calcium and, 260–263
chloride and, 307–310
Hgb, 690
urinalysis and, 1193
Fluid retention
hematocrit in, 369–372
hemoglobin in, 374–378
MRI for, 855–857
Fluid specimen, 1263
Fluorescence in situ hybridization (FISH) in bladder cancer, 218
in breast cancer, 177, 178
Fluorescent treponemal antibody testing (FTA-ABS), 1081
Fluoride, 1051
Fluorine-18, 598
Fluorodeoxyglucose (FDG), 598
Fluorodeoxyglucose (FDG)-PET scan, 598–601
Fluoroscopy technique, 1172
Fluorosis, 920–922
Flushing, antidepressant toxicity and, 124–128
FMH (fetal-maternal hemorrhage), 773
Focal fibrosis, 1143–1147
Focal radionuclide uptake, 971–973
Focal seizure
EEG determining, 563–564
PET scan for, 963–966
Focal uptake, 971–973
Folate/folic acid, 626–628
Folate/folic acid deficiency
alkaline phosphatase levels in, 25–26
amino acid levels in, urine test for, 40
bone marrow biopsy for, 174–177
haptoglobin level in, 686–687
homocysteine level and, 710–711
platelet count in, 380–382
RBC morphology in, 393–396
uric acid level in, 1189–1191
WBC and differential in, 399–403
Folex, 739–742
Follicle-stimulating hormone (FSH), 628–631
Follitropin, 628
Food. See Diet
Foot
MRI of, 847
venipuncture of, 1253–1254
x-ray of, 1027–1029
Forced expiratory flow, 1013
Forced expiratory volume, 1013
Forced inspiratory flow, 1013–1014
Forced vital capacity (in 1 second), 1013
Foregut carcinoid tumor, 724–726

Foreign body  
   bronchoscopy for, 250–253  
   chest x-ray for, 302–303  
   colonoscopy for, 347–350  
   otoscopy for, 906–907  
   radiography for, 1028–1029  
   upper GI series for, 1172–1174

Forward grouping, 233

Fracture  
   alkaline phosphatase levels in, 24–26  
   arthroscopy of, 147–149  
   bone mineral densitometry for risk of, 242–245  
   bone scan for, 245–248  
   chest x-ray for, 302–303  
   MRI for, 848–850  
   radiography of, 1028–1029  
   spinal CT for, 446–449  
   vertebroplasty for, 1212  
   x-ray of, 1027–1029

Framingham algorithm, 1108

FRC (functional residual capacity), 1013

Free erythrocyte protoporphyrin test, 575–577

Free thyroxine (FT\textsubscript{4}), 1099–1101

Free triiodothyronine (FT\textsubscript{3}), 1112–1113

Fructosamine, 631–633

Fructose, semen analysis and, 1057–1059

Fructose intolerance  
   aldolase levels in, 18–19  
   blood test for amino acid levels in, 37–38  
   urine test for amino acid levels in, 40

FSH (follicle-stimulating hormone), 628–631

FSP (fibrin split product), 617–619

FT\textsubscript{4} (free thyroxine), 1099–1101

Fructose, semen analysis and, 1057–1059

Fructose intolerance  
   aldolase levels in, 18–19  
   blood test for amino acid levels in, 37–38  
   urine test for amino acid levels in, 40

Gamma-glutamyl transpeptidase (GGT), 669–672

Gammapathy. See also Monoclonal gammapathy  
   IFE and, 731–733  
   IgA and IgG in, 735–736  
   total protein and, 995–998

Ganglioblastoma  
   catecholamine levels in, 287–290  
   homovanillic acid level in, 712–714

Ganglion, 147–149

Ganglion cyst, arthroscopy of, 146–149

Ganglion nerve cell, 896–898

Ganglioneuroma  
   catecholamine levels in, 287–290  
   metanephrine levels and, 872–873  
   vanillylmandelic acid level in, 1203–1205

Gangrene, ALD levels in, 18–19

Gas  
   abdominal laparoscopy and, 783  
   excessive, KUB study for, 771–772  
   gynecologic laparoscopy and, 786  
   hysterosalpingography and, 728

angiography in, 59, 63, 67, 71, 75, 79
Germ cell tumor, 715–717
German measles serology, 1051
Germinal follicle, 629–631
Gestational age sonogram, 1134–1139
Gestational diabetes
ketone level in, 767–770
vitamin B<sub>6</sub> and, 1228
Gestational screen test, standard, 665–668
GFR (glomerular filtration rate) estimated, 477
renogram and, 1039–1042
GGT (gamma-glutamyltransferase), 669–672
GH. See Growth hormone (GH)
Giardia, 547–550
Giardia lamblia infection, 908–909
Giardiasis, 908–909
Gigantism
blood creatinine clearance test and, 477–479
human growth hormone levels in, 683–684
urine creatinine clearance test and, 482–484
Gilbert syndrome, 164–166
Gingival bleeding
aPTT in, 926–929
prothrombin time and, 1008–1011
Gland tissue destruction, 5–7
Glandular enlargement, 1167–1168
Glanzmann's thrombasthenia
bleeding time in, 220
clot retraction testing for, 336–337
Glaucoma
fluorescein angiography and, 624
fundus photography and, 634
gonioscopy for, 676–677
intraocular pressure and, 752–755
nerve fiber analysis for, 896–898
pachymetry and, 913–914
slit-lamp biomicroscopy and, 1062–1063
visual field test for, 1215–1217
Gleason grading, 208
Gliadin antibody, 115–117
Glioblastoma, 563–564
Glomerular filtration rate (GFR) estimated, 477
renogram and, 1039–1042
Glomerulonephritis
amino acid levels in, blood test for, 37–38
anti-glomerular basement membrane antibody and, 99–100
antineutrophilic cytoplasmic antibodies in, 103–104
antistreptolysin O antibody in, 110–111
Glomerulonephritis (continued)

- BUN level in, 1178–1180
- complement protein levels in, 357–358
- intravenous pyelography for, 756–758
- magnesium level and, 823–824
- MRI for, 833–835
- protein level in, 996–998
- renogram for, 1040–1042
- total cholesterol level in, 330–333
- ultrasonography for, 1145–1147
- urine creatinine clearance test and, 482–484

Glomerulosclerosis, diabetic, 1189

Gloves, isolation precautions and, 1279

Glucagon, 654–657

Ghucagonoma
- glucagon level in, 655–657
- glucose levels in, 658–662
- syndromes of, 654

Glucocorticoid excess, 268–271

Glucose. See also Hyperglycemia; Hypoglycemia
- copper and, 461
- decreased, PET scan for, 967–970
- hemoglobin and, 672
- in urine specimen, 1194, 1197
- insulin response to, 744–747
- levels by age, 657
- symptoms of excess, 660

Glucose intolerance, TG and, 1109–1111

Glucose metabolism, potassium and, 974–978

Glucose tolerance test (GTT), 665–669

Glucose-6–phosphate dehydrogenase (G6PD), 662

Glucose-6–phosphate dehydrogenase deficiency (G6PDD)
- erythrocyte sedimentation rate and, 577–578
- sweat chloride values in, 312–314
- uric acid level in, 1186–1188

Glutamic acid, 39–41

Glutamine, 39–41

Gamma-glutamyltransferase, 669–672

Gluten sensitivity
- albumin/globulin ratio, 16–18
- gliadin antibody in, 116–117
- Gluten-induced enteropathy, 547–550
- Glycated albumin, 631–633
- Glycated hemoglobin A1C, 672–674
- Glycine, 39–41

Glycogen storage disease
- glucose levels in, 659–662
- ketone level in, 767–770
- total cholesterol level in, 330–333
- triglyceride levels and, 1109–1111

Glycogenolysis, vitamin B6, 1226–1230

Glycolysis, PK and, 1020

Glycoside, cardiac, 595–597

Goiter
- antithyroglobulin/antithyroid peroxidase antibody in, 112–113
- iodine-deficiency, 1021–1023, 1114–1116
- nontoxic nodular, 215–217
- radioactive iodine uptake and, 1021–1023
- thyroid scan for, 1090–1092
- ultrasonography for, 1167–1168

Gonadal failure
- follicle-stimulating hormone level in, 629–631
- luteinizing hormone secretion and, 815–816

Gonadotropin, human chorionic, 714–717

Gonadotropin-releasing hormone (GRH), 629–631

Gonadotropin-secreting pituitary tumor, 629–631

Gout, 940–942
- arthroscopy of, 147–149
- synovial fluid analysis and, 1078–1080
- total cholesterol level in, 330–333
- triglyceride levels and, 1109–1111
- uric acid level in, 1186–1188, 1189–1191
- WBC and differential in, 400–403

Gowns, 1281

G6PD. See Glucose-6–phosphate dehydrogenase entries

Graafian follicle, 629–631

Graded exercise tolerance test, 594–597

Graft. See Bypass graft

Graft diameter reduction, 1129–1131

Graft occlusion, 70–73

Graft versus host reaction, transfusion related, 1272

Gram stain, 501, 677–679

Gram-negative bacteria, 678

Gram-negative bacterial septicemia, 940–942

Gram-positive bacteria, 678

Gran mal seizure, 563–564

Granular cast, 1195

Granulocytic leukemia, 1218–1219
Granuloma
- lung biopsy for, 198–201
- MRI for, 837–839, 859–861
Granulomatous colitis, 157–159
Granulomatous disease, mediastinoscopy of, 868–871
Granulomatous infection
- mediastinoscopy for, 868–871
- platelet count in, 380–382
Granulomatous skin lesion, 488
Granulomatous thyroiditis, 215–217
Graves’ disease
- antithyroglobulin/antithyroid peroxidase antibody in, 112–113
- radioactive iodine uptake and, 1021–1023
- thyroglobulin values in, 1087–1088
- thyroid scan for, 1090–1092
- thyroid-binding inhibitory immunoglobulin and, 1089
- thyroid-stimulating hormone and, 1093–1095
- thyroid-stimulating immunoglobulin and, 1096–1097
- total thyroxine level and, 1102–1104
- ultrasonography for, 1167–1168
Grayish white feces, analysis of, 602–604
Green feces, analysis of, 602–604
GRH (gonadotropin-releasing hormone), 629–631
Gross hemolysis, 762
Group A streptococcal screen, 680–681
Group B streptococcus (GBS), culture for, 492, 493, 494
Growth hormone (GH)
- osteocalcin levels and, 904–905
- phosphorus levels in, 940–942
- stimulation and suppression tests for, 682–684
Growth pattern, x-ray for, 1027–1029
Growth plate, x-ray for, 1028–1029
Growth retardation, intrauterine, 792–795
Growth spurt, 904–905
GTT (glucose tolerance test), 665–669
Guillain-Barre syndrome
- antidiuretic hormone in, 129–130
- electromyography in, 565–567
- electroneurography in, 571–572
Gynecologic laparoscopy, 785–788
Gynecological carcinoma, 284–285
Gynecological ultrasonography, 1155–1158
Gynecomastia, 589–590

H
Haemophilus, 509–511
Haemophilus aegyptius, 494–497

Haemophilus influenzae
- bacterial culture for, 494–497
- bacterial pneumonia and, 502
Hair, fungal culture of, 514–516
Hair preparation, 563
Hairy cell leukemia, 795–797
Hallucination
- antidepressant toxicity and, 124–128
- quinidine toxicity and, 86–92
Haloperidol, 131–134
Hantavirus, 517–519
Haptoglobin, 685–687
Hartnup disease
- amino acid levels in, blood test for, 37–38
- amino acid levels in, urine test for, 40
- 5-hydroxyindoleacetic acid level in, 725–726
- vitamin B6 and, 1228
Hashimoto’s thyroiditis
- antithyroglobulin/antithyroid peroxidase antibody in, 112–113
- radioactive iodine uptake and, 1021–1023
- thyroid-stimulating hormone and, 1093–1095
HAV (hepatitis A virus), 693–695
Hay fever
- eosinophil count in, 573–575
- immunoglobulin E level in, 734–735
- immunoglobulin levels in, 27–28
HBV (hepatitis B virus), 1289–1290
HCG (human chorionic gonadotropin), 714–717
- quad-marker testing and, 613, 715
- triple-marker testing and, 613, 614, 715
Hct. See Hematocrit
hCT (calcitonin), 256–259
HCV. See Hepatitis C
HDLC (high-density lipoprotein cholesterol), 325–329
HDV (hepatitis D virus), 700
Head
- CT of, 416–420
- fetal, ultrasonography of, 1134–1139
Head and neck cancer
  CA 19–9 in, 282–284
  CEA and, 283
  mediastinoscopy and, 868–871
Head injury
  blood gas analysis in, 226–232
  brain CK-BB and, 474–475
  chloride values in, 307–310
  EEG determining, 563–564
  PET scan for, 963–966
Headache
  MRI for, 858–861
  visual field test for, 1215–1217
Healing, fracture
  bone scan for, 245–248
  x-ray for, 1027–1029
Hearing aid, 1122–1125
Hearing loss/deafness
  audiometry in, 153–156
  otoscopy for, 905–907
  spondee speech recognition threshold for, 1071–1073
  tuning fork test for, 1122–1125
Heart
  blood pool imaging and, 237–241
  cardiac scoring of, 421–424
  chest x-ray for enlargement of, 302–303
  cholinesterase in, 1030
  Doppler ultrasound of, 551–554
  electrocardiogram of, 557–561
  exercise stress test for, 594–597
  FDG-PET scan of, 598–601
  MRI of, 844–846
  myocardial perfusion scan of, 888
Heart disease
  alcohol abuse and, 544–547
  electrocardiogram for, 558–561
  folate deficiency and, 626
  platelet count in, 379–382
  total cholesterol level in, 330–333
  triglyceride levels and, 1109–1111
Heart failure. See Cardiac failure and Congestive heart failure
Heart rate
  ECG and, 557–561
  target, 594–597
Heart rhythm, 558
Heart scan, myocardial perfusion, 888–893
Heart transplant rejection, cyclosporine and, 740–742
Heart valve function, 558–561
Heart vessel calcium, CT for, 421
Heartburn. See also Gastroesophageal reflux (GER)
  barium swallow and, 160–162
  EM and, 582–585
Heat sensitivity, RAIU and, 1081
Heavy metal poisoning. See Metal toxicity
Heel, venipuncture of, 1253–1254
Heinz bodies, 364, 392, 1044
Helical/spiral CT, 412, 416–420, 421
  Helicobacter pylori antibody, 687–688
  Helicobacter pylori colonization, 688
  Helicobacter pylori infection, 688,
    1175–1177
Helmet cell, 364, 392
Helminth, 733
Hemangioma
  liver and spleen scan for, 801–803
  MRI for, 848–850
  ultrasonography for, 1129–1131
Hematemesis, 1172–1174
Hematocoele, 1161–1163
Hematocrit
  aPTT and, 927
  complete blood count and, 361,
    365–367, 367–372
Hematologic disorders
  CBC and, 368
  Hgb and, 374
  RBC count and, 384
  RBC indices and, 389
  RBC morphology and, 393
  WBC count and, 399
Hematoma
  abdominal CT of, 404–407
  aPTT in, 926–929
  bilirubin levels in, 163–166
  brain CT of, 417–420
  intravenous pyelography for, 756–758
  kidney CT for, 441–445, 442–445
  liver and spleen scan for, 801–803
  liver/biliary tract CT of, 412–416
  mammography for, 862–864
  MRI for, 840–843
  prothrombin time and, 1008–1011
  splenic CT of, 450–453
  thyroid scan for, 1090–1092
  ultrasonography for, 1129, 1143,
    1148, 1162
  voiding cystourethrography for, 527–529
Hematopoiesis, 1217
Hematopoietic system
  diagnostic tests for, 1242
  laboratory tests for, 1241–1242
Hematuria
  aPTT in, 926–929
  prothrombin time and, 1008–1011
Heme synthesis, 959–960
Hemochromatosis, 691–693
  ferritin level in, 609–610
  follicle-stimulating hormone level in, 630–631
glucose levels in, 658–662
  glucose tolerance test for, 666–669
  iron level in, 762–764
  liver biopsy for, 194–197
  total iron-binding capacity and, 765–766
Hemoconcentration
  hematocrit in, 369–372
  hemoglobin in, 374–378
Hemodialysis
  aPTT in, 927–929
  ferritin level in, 609–610
  lipase levels and, 798
  magnesium level and, 823–824
  vitamin C and, 1228
Hemoglobin
  complete blood count and, 361, 365–367, 372–378
  glucose and, 672
  glycated, 672–674
  in urine specimen, 1194
  iron and, 764–765
Hemoglobin A₂, 689
Hemoglobin Bart's hydrops fetalis syndrome, 690
Hemoglobin C crystals, 364, 392
Hemoglobin C disease
  erythrocyte sedimentation rate and, 577–578
  hemoglobin electrophoresis for, 689–691
  RBC morphology in, 393–396
Hemoglobin C Harlem anemia, 1060–1061
Hemoglobin content, 392
Hemoglobin D, electrophoresis and, 689–691
Hemoglobin E, 689–690
Hemoglobin F, 689, 772
Hemoglobin H disease, 690
Hemoglobin M, 874
Hemoglobin S, 689–690, 1060
Hemoglobinopathy, 1060–1061
  haptoglobin level in, 686–687
  hemoglobin in, 374–378
  osmotic fragility and, 902–903
  RBC count in, 384–388
Hemoglobinuria. See also Paroxysmal nocturnal hemoglobinuria (PNH)
  Ham’s test for, 1143–1147
  platelet antibody and, 948–949
Hemolysis
  as transfusion reaction, 1272
  haptoglobin level in, 686–687
  iron level and, 762
  magnesium level and, 822–824
  potassium levels and, 975–978
  protein level and, 997
  vitamin B₁₂ and, 1218
Hemolytic anemia, 457–458
  acquired, osmotic fragility and, 902–903
  aldolase levels in, 18–19
  aspartate aminotransferase levels in, 150–152
  autoimmune, 357–360, 457–458
  bilirubin levels in, 164–166
  bone marrow biopsy for, 174–177
  cholinesterase enzyme in, 1030–1032
  chronic, 393–396
  ferritin level in, 609–610
  folate level in, 627–628
  free erythrocyte protoporphyrin test for, 576–577
  glycated hemoglobin A₁C and, 673–674
  hemoglobin levels in, 692–693
  human chorionic gonadotropin level in, 716–717
  iron level in, 762–764
  lactate dehydrogenase levels in, 775–776
  microangiopathic, 692–693
  platelet count in, 379–382
  RBC count in, 384–388
  RBC morphology in, 393–396
  total iron-binding capacity and, 765–766
  vitamin E and, 1222–1224
Hemolytic disease, 457–458
Hemolytic disease of newborn, 902–903
  carbon dioxide levels in, 280–282
  DAT and, 459–460
  hematocrit in, 369–372
  hemoglobin in, 374–378
  osmotic fragility and, 902–903
  platelet count and, 380–382
Hemolytic jaundice, 163–166
Hemolytic transfusion reaction, 692–693
Hemolyzed specimen, 949
Hemoperitoneum
  abdominal CT of, 404–407
  splenic CT of, 450–453
Hemophilia, 926–929
Hemophilic arthritis, 1078–1080
Hemoptysis, 74–77
Hemorrhage. See also Bleeding disorders; Blood loss
  abdominal laparoscopy and, 783
  albumin/globulin ratio, 16–18
  bone marrow biopsy for, 174–177
  brain CT of, 417–420
  BUN level in, 1178–1180
  CT angiography of, 409–412
  EEG determining, 563–564
Hemorrhage (continued)
  fetal-maternal, 773
  hematocrit in, 369–372
  hemoglobin in, 374–378
  lactic acid levels and, 777–779
  Meckel’s diverticulum scan for, 865–867
  pituitary CT of, 438–441
  platelet count in, 380–382
  proctosigmoidoscopy for, 986–988
  RBC count in, 384–388
  splenic CT of, 450–453
  stereotactic biopsy and, 1075
  ultrasonography for, 1155–1158
  visual field test for, 1215–1217
Hemorrhagic cystitis, 518–519
Hemorrhagic fever, 518–519
Hemorrhagic pericarditis, 932–934
Hemorrhoid
  colonoscopy for, 347–350
  fecal analysis for, 603–604
  proctosigmoidoscopy for, 986–988
Hemosiderin, 691–693, 765
Hemosiderin stain, 691–693
Hemosiderosis, 609–610
Hemostasis, 1008–1011
Hemostatic platelet plug, 617
Hemothorax, 956–958
Hepadnaviridae family, 695
Heparin cofactor assay, 134–136
Heparinization, 1256–1257
Hepatectomy, 135–136
Hepatic. See also Liver entries
  AcP levels in, 4
  alanine aminotransferase levels in, 13–15
  albumin/globulin ratio, 16–18
  alcohol abuse and, 544–547
  alkaline phosphatase levels in, 24–26
  antimitochondrial/antismooth muscle antibody in, 101–102
  antineutrophilic cytoplasmic antibodies in, 103–104
  apolipoprotein B and, 141–143
  aPTT in, 926–929
  bleeding time in, 220
  blood creatinine clearance test and, 478–479
  bone marrow biopsy for, 174–177
  BUN level in, 1178–1180
  coagulation factors in, 339–341
  complement protein levels in, 357–358, 359–360
  fibrin degradation product and, 618–619
  fibrinogen level in, 620–622
  folate level in, 627–628
  GGT levels in, 670–672
  glucose levels in, 658–662
  glucose tolerance test for, 666–669
  haptoglobin level in, 686–687
  hemoglobin in, 761
  immunoglobulin E level in, 737–738
  insulin levels in, 745–747
  iron level in, 761
  LDLC level in, 327–329
  osmotic fragility and, 902–903
  plasminogen levels in, 946–947
  prealbumin and, 983–984
  protein C levels and, 999–1001, 1002–1003
  protein level in, 996–998
  prothrombin time and, 1008–1011
  TBG level in, 1098–1099
  total cholesterol level in, 331–333
  liver/biliary tract CT of, 412–416
Hepatic damage
  amino acid levels in, blood test for, 37–38
  bilirubin levels in, 164–166
  bone marrow biopsy for, 174–177
  lactic acid levels and, 777–779
  prealbumin and, 983–984
  transferrin level in, 1106–1108
  vitamin B12 and, 1218–1219
Hepatic disease. See also Cirrhosis
  AcP levels in, 4
  alanine aminotransferase levels in, 13–15
  albumin/globulin ratio, 16–18
  alcohol abuse and, 544–547
  alkaline phosphatase levels in, 24–26
  antimitochondrial/antismooth muscle antibody in, 101–102
  antineutrophilic cytoplasmic antibodies in, 103–104
  apolipoprotein B and, 141–143
  aPTT in, 926–929
  bleeding time in, 220
  blood creatinine clearance test and, 478–479
  bone marrow biopsy for, 174–177
  BUN level in, 1178–1180
  coagulation factors in, 339–341
  complement protein levels in, 357–358, 359–360
  fibrin degradation product and, 618–619
  fibrinogen level in, 620–622
  folate level in, 627–628
  GGT levels in, 670–672
  glucose levels in, 658–662
  glucose tolerance test for, 666–669
  haptoglobin level in, 686–687
  hemoglobin in, 761
  immunoglobulin E level in, 737–738
  insulin levels in, 745–747
  iron level in, 761
  LDLC level in, 327–329
  osmotic fragility and, 902–903
  plasminogen levels in, 946–947
  prealbumin and, 983–984
  protein C levels and, 999–1001, 1002–1003
  protein level in, 996–998
  prothrombin time and, 1008–1011
  TBG level in, 1098–1099
  total cholesterol level in, 331–333
  liver/biliary tract CT of, 412–416
total iron-binding capacity and, 765–766
total thyroxine level and, 1102–1104
triglyceride levels and, 1110–1111
uric acid level in, 1187–1188
urine urea nitrogen level in, 1180–1182
vitamin E and, 1223–1224
vitamin K and, 1225–1226
ZZ deficiency in, 137
Hepatic failure, 1065–1067
ammonia levels in, 44–45
antithrombin III levels in, 135–136
prolactin level in, 991–993
Hepatic hemangioma, ultrasonography of, 1129–1131
Hepatic hematoma, ultrasonography of, 1129–1131
Hepatic injury. See also Hepatic damage
CT of, 412–416
liver and spleen scan of, 800–803
Hepatic insufficiency, 1085–1086
Hepatic jaundice, 164–166
Hepatic metastasis, 1024–1027
Hepatic necrosis, 40
Hepatic obstruction
apolipoprotein B and, 141–143
LDLC level in, 327–329
ultrasonography for, 1148–1149
Hepatic polyp, ultrasonography of, 1148–1149
Hepatic porphyria, 960–962
Hepatic transplantation, 135–136
Hepatic tumor. See also Hepatic carcinoma
aspartate aminotransferase levels in, 150–152
bilirubin levels in, 164–166
ultrasonography for, 1148–1149
Hepatitis
AFP levels in, 614–617
alanine aminotransferase levels in, 13–15
aldolase levels in, 18–19
alkaline phosphatase levels in, 24–26
amino acid levels in, urine test for, 40
antimitochondrial/antismooth muscle antibody in, 101–102
antithrombin III levels in, 135–136
aspartate aminotransferase levels in, 150–152
beta₂-microglobulin levels in, 880–883
bilirubin levels in, 164–166
complement protein levels in, 357–358
cryoglobulin detection in, 485–486
GGT levels in, 670–672
G6PD levels in, 663
HDLC level in, 326–329
lactate dehydrogenase levels in, 775–776
liver and spleen scan for, 801–803
liver biopsy for, 194–197
percutaneous transhepatic cholangiography for, 315–318
pseudocholinesterase level in, 1012
renin value in, 1036–1039
rheumatoid factor and, 1049–1050
TBG level in, 1098–1099
total thyroxine level and, 1102–1104
ultrasonography for, 1148–1149
vitamin B_{12} and, 1218–1219
WBC and differential in, 400–403
Hepatitis A antibody, 693–695
Hepatitis B, 1289–1290
Hepatitis B antigen/antibody, 695–698
Hepatitis C, isolation precautions for, 1289–1290
Hepatitis C antibody, 698–700
Hepatitis D antibody, 700
Hepatobiliary scan, 701–704
Hepatobiliary system
diagnostic tests for, 1243–1244
laboratory tests for, 1243
Hepatobiliary system disorders
GGT levels in, 670–672
natural products affecting, 1275–1276
Hepatobiliary ultrasonography, 1147–1149
Hepatoblastoma, 614–617
Hepatocellular carcinoma, 670–672
Hepatocellular disorder
apolipoprotein A and, 141–143
aspartate aminotransferase levels in, 150–152
bilirubin levels in, 164–166
ferritin level in, 609–610
HDLC and LDLC levels in, 326–329
immunoglobulin E level in, 737–738
pseudocholinesterase level in, 1012
ultrasonography for, 1148–1149
Hepatolenticular degeneration, 268–271
Hepatoma
beta₂-microglobulin levels in, 880–883
erththropoietin level in, 581–582
Hepatomegaly, 1148–1149
Hepatotoxic drugs, BUN and, 1177–1180
HER-2 (human epidermal growth factor receptor 2)/neu oncoprotein, in breast cancer, 177, 178
Herbals, 606
Hereditary angioedema, 357–358
Hereditary atransferrinemia, 357–358
Hereditary fructose intolerance. See Fructose intolerance
Hereditary hematologic disorders. See Hematologic disorders
Hereditary hyperoxaluria, 910
Hereditary hypophosphatemia, 796–797
Hereditary methemoglobinemia, 874
Hereditary predispositions, PFTs and, 1012–1017
Hereditary pyruvate kinase deficiency, 902–903
Hereditary spherocytosis
bone marrow biopsy for, 174–177
osmotic fragility and, 902–903
RBC morphology in, 393–396
Hereditary telangiectasia, 220
Hereditary tyrosinemia. See Tyrosinemia
Hernia
abdominal laparoscopy and, 783
barium swallow for, 160–162
capsule endoscopy for, 274–276
diaphragmatic, 301–303
esophageal manometry for, 583
esophagogastrodoudenoscopy for, 586–589
ultrasanography for, 1161–1163
upper GI series for, 1172–1174
Hernia repair, inguinal, 109–110
Herniated disk, 446–449, 571–572
electromyography for, 565–567
MRI for, 848–850
Heroin abuse, 546
Herpangina, 518–519
Herpes
Pap smear and, 917
skin biopsy for, 212–214
Tzanck smear in, 212
Herpes simplex virus (HSV), 517–519
Heterophil antibody, infectious mononucleosis and, 742–744
Heterophoria, 750–752
Heterotropia, 750–752
Heterozygous biochemical enzyme defect, 709
Hexacarboxylporphyrin (porphyrin), 959–962. See also Porphyria
Hexosaminidase A and B, 704–706
Hgb. See Hemoglobin
5–HIAA (5–Hydroxyindoleacetic acid), 724–726
Hiatal hernia
barium swallow for, 160–162
capsule endoscopy for, 274–276
esophageal manometry for, 583
esophagogastrodoudenoscopy for, 586–589
upper GI series for, 1172–1174
HICPAC isolation precautions, 1283–1284
HIDA scan. See Hepatobiliary scan
High altitude
free triiodothyronine levels in, 1112–1113
hematocrit in, 369–372
hemoglobin in, 374–378
hemoglobin levels and, 690
High-altitude hypoxia, 581–582
High-density lipoprotein cholesterol, 325–329
High-fat diet, 767–770. See also Fatty diet
ketones and, 767–770
High-frequency hearing loss, 1071–1073
High-protein diet, 767–770
High-risk medications, 1216–1217
High-stress lifestyle, cardiac scoring and, 421–424
Hip
arthrogram of, 143–146
MRI of, 847
Hirschsprung’s disease, 157–159
Hirsutism
DHEAS and, 542–543
testosterone and, 1085–1086
Histidine, 39–41
Histoplasma, 198–201
Histoplasma capsulatum, 515–516
Histoplasmosis
angiotensin-converting enzyme in, 82–83
bronchscopy for, 250–253
calcium values in, 260–263
medistinoscopy for, 868–871
platelet count in, 380–382
HIV. See Human immunodeficiency virus (HIV)
Hodgkin’s disease
calcium values in, 260–263
ceruloplasmin levels in, 299–300
copper levels in, 462–463
eosinophil count in, 573–575
ferritin level in, 609–610
fibrinogen level in, 620–622
hemoglobin in, 374–378
LAP levels in, 795–797
liver and spleen scan for, 801–803
lymphangiography for, 819–821
mediastinoscopy for, 868–871
platelet count in, 379–382
RBC count in, 384–388
T-cell enumeration for, 292–293
thoracic CT for, 454–456
WBC and differential in, 400–403
Holter monitor, 707–709
Homocysteine, 709–711
Homocystine, 39–41
Homocystinuria, 710–711
Homovanillic acid (HVA), 712–714
Hookworm infection, 908–909
  D-xylose tolerance test for, 547–550
  immunoglobulin levels in, 27–28
Hordeolum, 1062–1064
Hormonal disturbance, 1028–1029
Hormonal therapy, 179–181
Hormone, 815
Horseshoe kidney
  kidney CT of, 442–445
  ultrasonography for, 1145–1147
Hospital, isolation precautions for, 1277–1283
Howell-Jolly bodies, 364, 392, 1044
HP (haptoglobin), 685–687
HPV (human papillomavirus), 517–519, 915–916
HSV (herpes simplex virus), 517–519
HTLV-I/HTLV-II (human T-lymphotropic virus, type I and II), 722–724
Human chorionic gonadotropin (HCG), 714–717
  quad-marker testing and, 613, 715
  triple-marker testing and, 613, 614, 715
Human epidermal growth factor receptor 2 (HER-2)/neu oncoprotein, in
  breast cancer, 177, 178
Human growth hormone, 682–684
Human immunodeficiency virus (HIV). See also
  Acquired immune deficiency syndrome (AIDS)
  alkaline phosphatase levels in, 25–26
  isolation precautions for, 1289–1290
  syphilis serology testing for, 1081–1083
  tuberculosis and, 487
  type 1 and type 2 antibodies of, 715–717
  viral culture for, 517–519
  WBC and differential in, 400–403
Human leukocyte antigen (HLA), 879
Human leukocyte antigen B27, 720–722
Human papillomavirus (HPV), 517–519, 915–916
Human T-lymphotropic virus type I and II, 722–724
Humoral immunity status, immunoglobulins and, 929–931
Huntington’s chorea
  amino acid levels in, blood test for, 37–38
  evoked brain potentials in, 591–594
  FDG-PET scan in, 598–601
  PET scan in, 963–966
HVA (homovanillic acid), 712–714
Hyaline casts, 1195, 1196
Hyaline membrane disease, 946–947
Hydatidiform mole
  AFP levels in, 615–617
  human chorionic gonadotropin level in, 715–717
  progesterone testing for, 989–990
Hydration, rapid, 16–18
Hydrazine exposure, 1228
Hydrocele, 1161–1163
Hydrocephalus
  MRI for, 837–839
  ultrasonography for, 1136–1139
Hydrocephaly, 417–420
Hydrocortisone, 463
Hydronephrosis
  intravenous pyelography for, 756–758
  KUB study for, 771–772
  MRI for, 833–835
  retrograde ureteropyelography for, 1045–1048
  ultrasonography for, 1145–1147
Hydrops fetalis, 930–931
Hydroxalpinx, 433–437
5–Hydroxyindoleacetic acid, 724–726
Hydroxylystine, 40–41
Hydroxyproline, 40–41
Hymenolepsis
  infection, 908–909
Hyperactivity, 131–134
Hyperaldosteronism, 254–255
  adrenal scan in, 5
  aldosterone levels in, 20–22
  magnesium level and, 823–824
  potassium levels and, 976–978, 980–982
  renin value in, 1036–1039
  sodium levels in, 1065–1067
Hyperalimentation, 823–824
Hyperalimentation therapy
  BUN level in, 1178–1180
  phosphorus levels in, 940–942
  vitamin levels and, 1229
Hyperbaric oxygenation, 227–232
Hypercalcemia
  calcitonin stimulation test for, 257–259
  calcium values in, 260–263
  osmotic concentration and, 900–902
  parathyroid scan for, 923–925
  phosphorus levels in, 940–942
  urinary calcium levels in, 268–271
  vitamin A and, 1227
Hypercalcemia, infantile, 141–143
Hypercalciumia, 911–912
Hypercapnia, 226–232
Hypercapnic state
  abdominal laparoscopy and, 783
  gynecologic laparoscopy and, 787
Hyperchromic cell, 394
Hypereosinophilic syndrome, 573–575
Hyperfusion, 15–18
Hypergammaglobulinemia, 84–86
Hypergastrinemia, 257–259
Hyperglycemia, 932–934
cause and effects of, 658
cortisol levels in, 465–467
erthyrocyte sedimentation rate and, 577–578
glucose tolerance test for, 665–669
ketone level in, 767–770
peritoneal fluid analysis and, 936–938
pleural fluid analysis and, 956
synovial fluid analysis and, 1078
Hyperhomocysteinemia, 626
Hyperhomocystinuria, 709
Hyperinsulinemic hypoglycemia, 745–747
Hyperinsulinism, 940–942
Hyperkalemia
electrocardiogram for, 559–561
potassium levels and, 976
renin value and, 1037
Hyperlipidemia
DHEAS and, 542–543
glucose tolerance test for, 666–669
type III, uric acid level in, 1186–1188
Hyperlipoproteinemia, 799–800
apolipoprotein B and, 141–143
glucagon level in, 655–657
LDLC level in, 327–329
total cholesterol level in, 330–333
triglyceride levels and, 1109–1111
Hypernatremia
osmotic concentration and, 900–902
sodium levels in, 1066–1067
Hyperopia, 1032–1035
Hyperoxaluria, 910
Hyperparathyroidism
alkaline phosphatase levels in, 24
amino acid levels in, urine test for, 40
calcium values in, 260
chloride values in, 307
gastrin stimulation test for, 645
ionized calcium values in, 265
NT x, for, 345–346
parathyroid hormone levels in, 920–922
phosphorus levels in, 940–942, 943–945
uric acid level in, 1186–1188
urinary calcium levels in, 268–271
Hyperphosphatemia, 261–263, 939
Hyperpituitarism, 683–684
Hyperprolactinemia
DHEAS and, 542–543
follicle-stimulating hormone level in, 630–631
Hyperpyrexia, 1058–1059
Hypersensitivity pneumonitis serology, 727
Hypersensitivity reaction, 174–177
Hypersplenism
haptoglobin level in, 686–687
WBC and differential in, 400–403
Hypertension, 254–255
Hypertension
aldosterone levels in, 20–22
cocaine intoxication, 545
exercise stress test for, 595–597
GGT levels in, 670–672
lecithin/sphingomyelin ratio in, 792–795
liver and spleen scan for, 801–803
lung perfusion scan for, 805–807
microalbumin and, 877–879
potassium levels and, 976–978
renin value in, 1036–1039
triglyceride levels and, 1109–1111
uric acid level in, 1186–1188
vanillylmandelic acid level in, 1203–1205
Hypertensive retinopathy, 623–625
Hyperthermia
blood gas analysis in, 227–232
myoglobin levels in, 894–895
phosphorus levels in, 940–942
skeletal muscle CK-MM and, 474–475
Hyperthyroidism
angiotensin-converting enzyme in, 83
beta2–microglobulin levels in, 880–883
blood creatinine clearance test and, 478–479
catecholamine level and, 1203
copper levels in, 462–463
estriadiol level in, 589–590
ferritin level in, 609–610
free thyroxine level and, 1100–1101
free triiodothyronine levels in, 1112–1113
GGT levels in, 670–672
glucose tolerance test for, 666–669
G6PD levels in, 663
intrinsic factor antibody and, 759–760
LDLC level in, 327–329
metanephrine levels and, 872–873
osteocalcin levels and, 904–905
parathyroid hormone levels in, 921–922
protein level in, 996–998
pseudochoolinesterase level in, 1011–1012
radioactive iodine uptake and, 1021–1023
TBG level in, 1098–1099
testosterone and, 1085–1086
thyroid-binding inhibitory immunoglobulin and, 1089
thyroid-stimulating hormone and, 1093–1095
total cholesterol level in, 331–333
total thyroxine level and, 1102–1104
total triiodothyronine levels and, 1114–1116
triglyceride levels and, 1109–1111, 1110–1111
urinary calcium levels in, 268–271
urine urea nitrogen level in, 1180–1182
vitamin C and, 1228
Hypertriglyceridemia
apolipoprotein A and, 141–143
HDL C level in, 326–329
Hypertrophic anal papillae, 985–988
Hypertrophic cardiomyopathy, 555–557
Hyperventilation
blood gas analysis in, 227–232
chloride values in, 308–310
effect on ECG, 560
potassium levels and, 975–978
Hypervolemia, 16–18
Hypoalbuminemia, 261–263
radioactive iodine uptake and, 1022–1023
Hypoaldosteronism
aldosterone levels in, 20–22
potassium levels and, 975–978
sweat chloride values in, 312–314
Hypocalcemia
EEG determining, 563–564
electrocardiogram for, 559–561
electromyography for, 566–567
phosphorus levels in, 940–942
urinary calcium levels in, 269–271
Hypocalciuric hypercalcemia, 269–271
Hypochloremic state, 227–232
Hypochlorhydria, 1218–1219
Hypochromia, 364, 392
Hypochromic anemia, 461–463
RBC indices in, 390–391
total iron-binding capacity and, 765–766
Hypochromic cell, 394
Hypofibrinogenemia
erythrocyte sedimentation rate and, 577–578
prothrombin time and, 1008–1011
Hypoglycemia, 932–934
catecholamine level and, 1203
C-peptide levels in, 468–469
EEG determining, 563–564
effect on EEG, 563
glucagon level in, 655–657
peritoneal fluid analysis and, 936–938
pleural fluid analysis and, 956
prolactin level in, 991–993
synoval fluid analysis and, 1078
Hypogonadism
estriol level in, 589–590
follicle-stimulating hormone level in, 629–631
progesterone testing for, 989–990
testosterone and, 1085–1086
Hypokalemia
blood gas analysis and, 227–232
electrocardiogram for, 559–561
gastric emptying scan for, 643–645
myocardial perfusion heart scan and, 890
phosphorus levels in, 940–942
potassium levels and, 976
renin value in, 1036–1039
Hypokinesia, 239–241
Hypolipoproteinemia
LDLC level in, 327–329
triglyceride levels and, 1110–1111
Hypomagnesemia, 261–263
gastric emptying scan for, 643–645
parathyroid hormone levels in, 921–922
potassium levels and, 976–978
Hyponatremia, 84–86
osmotic concentration and, 900–902
renin value in, 1036–1039
sodium levels in, 1066–1067
Hypoparathyroidism
alkaline phosphatase levels in, 24
ionized calcium values in, 265–267
parathyroid hormone levels in, 921–922
phosphorus levels and, 943–945
phosphorus levels in, 940–942
sweat chloride values in, 311–314
uric acid level in, 1186–1188
urinary calcium levels in, 269–271
Hypophosphatemia, 796–797
Hypopituitarism
ACTH levels in, 10
cortisol levels in, 466–467
human growth hormone levels in, 683–684
testosterone and, 1085–1086
Hypoprothrombinemia, 1225–1226
Hypotension
catecholamine levels in, 288–290
heroin and, 546
Hypothalamic disorder
   follicle-stimulating hormone level in, 630–631
   prolactin level in, 991–993
Hypothalamic dysfunction, 815–816
Hypothermia
   as transfusion reaction, 1271
   effect on EEG, 563
   heroin and, 546
   skeletal muscle CK-MM and, 474–475
Hypothyroidism, 1093–1095
   apolipoprotein B and, 141–143
   bilirubin levels in, 164–166
   blood gas analysis in, 226–232
   carbon dioxide levels in, 277–279
   catecholamine levels in, 287–290
   copper levels in, 462–463
   free thyroxine level and, 1100–1101
   free triiodothyronine levels in, 1112–1113
   gastrin stimulation test for, 645–647
   GGT levels in, 670–672
   glucose tolerance test for, 666–669
   hyperlipoproteinemia and, 799–800
   iron level in, 762–764
   LDLC level in, 327–329
   magnesium level and, 822–824
   prolactin level in, 991–993
   radioactive iodine uptake and, 1021–1023
   RBC morphology in, 393–396
   skeletal muscle CK-MM and, 474–475
   sweat chloride values in, 312–314
   total cholesterol level in, 330–333
   total thyroxine level and, 1102–1104
   total triiodothyronine levels and, 1115–1116
   urinary calcium levels in, 269–271
   vitamin A and, 1228
Hypoventilation
   blood gas analysis in, 227–232
   carbon dioxide levels in, 277–279
   lung ventilation scan for, 808–810
Hypovolemia, 1178–1180
Hypoxemia
   blood gas analysis in, 227–232
   pulse oximetry for, 1018–1020
Hypoxia, 595–597
   erythropoietin level in, 581–582
   Holter monitor and, 707–709
   lactate dehydrogenase levels in, 775–776
   platelet count in, 380–382
   RBC count in, 384–388
   sputum cytology and, 530
Hypoxic shock, 474–475
Hypoxic state
   abdominal laparoscopy and, 783
   gynecologic laparoscopy and, 786
Hysteria, 227–232
Hystero gram, 727
Hysterosalpinography, 727–730
ICSH (interstitial cell-stimulating hormone), 813–816
Icteric specimen, 811
Idiopathic hypercalcemia
   calcium values in, 260–263
   urinary calcium levels in, 268–271
Idiopathic inflammatory myopathy, 106–108
Idiopathic myxedema, 112–113
Idiopathic pulmonary hemosiderosis, 99–100
Idiopathic sexual precocity, 1085–1086
Idiopathic thrombocytopenic purpura (ITP)
   G6PD levels in, 663
   LAP and, 796
   platelet antibody and, 948–949
Ig. See Immunoglobulin entries
Ileal resection, 910–912
Ileitis, 1009–1011
Imipramine, 124–128
Immobilization
   albumin/globulin ratio, 16–18
   protein level in, 996–998
   urinary calcium levels in, 268–271
Immune complex disease
   complement protein levels in, 357–358
   platelet antibody and, 948–949
Immune disorder, 1276
Immune system
   diagnostic tests for, 1245
   laboratory tests for, 1244–1245
Immuno compromised patient
   cytomegalovirus and, 537
   isolation precautions and, 1284–1285
Immuno deficiency acquired. See Acquired immune deficiency syndrome (AIDS)
   familial, 734–735
   immunofixation electrophoresis for, 731
   immunoglobulin E level in, 737
   lymph node biopsy for, 202–205
   Immunofixation electrophoresis, 731–733
   Immunoglobulin A (IgA), 735–738
   anti-insulin properties of, 748
   deficiency of, 737, 997
   gliadin antibodies as, 115–117
   Immunoglobulin D (IgD), 735–738
   anti-insulin properties of, 748
   genetic deficiency of, 737
   Immunoglobulin E (IgE), 733–735
   allergen-specific, 26–28
anti-insulin properties of, 748
deficiency of, 734
Immunoglobulin E (IgE) myeloma, 734–735
Immunoglobulin G (IgG), 113–115, 735–738, 929–931
anti-insulin properties of, 748
cellular damage and, 457
CSF analysis and, 294, 295
cytomegalovirus and, 537–538
genetic deficiency of, 737
gliadin antibodies as, 115–117
levels by age, 735–736
lupus anticoagulant, 811
Lyme disease and, 816
mumps and, 883
parvovirus B19, 929–931
platelet-bound, 948–949
rubella, 1051
rubella, 1053
varicella, 1206
Immunoglobulin M (IgM), 113–115, 735–738
anti-insulin properties of, 748
cytomegalovirus and, 537–538
EBV infection and, 742
infection and, 883
levels by age, 735–736
Lyme disease and, 816
mumps and, 883
parvovirus B19, 929–931
platelet-bound, 948–949
rubella, 1051
rubella, 1053
secondary deficiency of, 737
varicella, 1206
Immunoglobulin-mediated cytotoxic chemical, 733
Immunoproliferative disorder, 731
Immunosuppressant, 739–742
Immunosuppressive therapy, 738
Impaired glucose tolerance, 1109–1111
Impaired glucose tolerance test, 665
Impedance plethysmography, 950–954
Impotency, 1085–1086
Inborn enzyme deficiency, 44–45
Incontinence
cystometry for, 520–523
sphincter muscle electromyography and, 568–570
voiding cystourethrography for, 527–529
Increased latency, 591
Indirect antiglobulin testing (IAT), 459–460
Indirect contact transmission of pathogen, 1277
Indirect platelet-bound IgG/IgM, 948–949
Indwelling catheter
for bacteria culture, 513
for magnesium measurement, 826
for microalbumin testing, 878
for urinalysis, 1198
for urine cytology, 535–536
hemosiderin stain and, 692–693
osmolality and, 901
oxalate levels and, 912
porphyrin levels and, 960–962
potassium levels and, 981
Infant. See also Child
age-specific communication and, 1265
amino acid screen in, 39–41
aminoacidopathy testing in, 35–38
anniotic fluid analysis and, 47–51
bilirubin levels in, 164–166
binocularity in, 591–594
blood gas analysis in, 221–232
calcium values in, 259–260
carbon dioxide measurement in, 276
Chlamydia antibody testing in, 304–306
complement proteins in, 356
DAT and, 459–460
direct antitglobulin testing (DAT) of, 457–458
fibrinogen level in, 620–622
gastroesophageal reflux scan in, 648–650
glucose levels in, 657
haptoglobin level in, 685
hearing loss audiometry in, 156
hyperphosphatemia in, 939
hypoglycemia in, 745
idiopathic hypercalcemia, 260
metanephrine levels in, 871
methemoglobinemia in, 875
protein level in, 996
radiography of, 1028–1029
RBC morphology in, 393–396
respiratory distress syndrome in, 791
reticulocyte count in, 1042
sodium levels in, 1065
total CK in, 472
vitamin B12 level in, 1217
vitamin E deficiency and, 1222–1224
vitamin K and, 1225–1226
zinc deficiency in, 1234
Infantile hypercalcemia, 141–143
Infarct/infarction. See site-specific entries, e.g., Cerebral infarction; Myocardial infarction
Infarct scan, 750–752
Infection. See also specific pathogens
abdominal laparoscopy and, 783
adrenal scintiscan for, 5–7
amniotic fluid analysis for, 48–51
bacterial. See Bacterial infection
Infection (continued)

- beta2–microglobulin levels in, 881–883
- bone marrow biopsy for, 174–177
- brain CT of, 417–420
- bronchoscopy for, 250–253
- ceruloplasmin levels in, 299–300
- Chlamydia antibody testing for, 304–306
- colonoscopy for, 347–350
- colposcopy for, 353–355
- complement protein levels in, 357–358, 359–360
- copper levels in, 462–463
- CRP assay for, 470–472
- cystoscropy for, 524–526
- echocardiography for, 551–554
- eosinophil count in, 573–575
- erythrocyte sedimentation rate and, 577–578
- FDG-PET scan for, 599–601
- ferritin level in, 609–610
- fungal. See Fungal infection
gallium scan for, 636–638
- genital, 916–919
- glucagon level in, 655–657
- glucose tolerance test for, 666–669
- haptoglobin level in, 686–687
- hearing loss audiometry for, 154–156
- immunoglobulin E level in, 737–738
- infertility and, 109–110
- iron level in, 762–764
- isolation precautions for, 1277–1284
- liver and spleen scan for, 801–803
- lung biopsy for, 198–201
- lymph node biopsy for, 202–205
- MRI for, 833–835, 848–850, 855–857
- parasitic. See Parasitic infection
- peritoneal fluid analysis for, 935–938
- platelet count in, 380–382
- pseudocholinesterase level in, 1011–1012
- radiography for, 1028–1029
- slit-lamp biomicroscopy for, 1062–1064
- stereotactic biopsy and, 1075
- sweat chloride values in, 311–314
- total iron-binding capacity and, 765–766
- transferrin level in, 1106–1108
- ultrasonography for, 1150–1152, 1156–1158, 1164–1166
- viral. See Viral infection
- vitamin A and, 1228
- WBC and differential in, 399–403
- white blood cell scan for, 1231–1233
- zinc level in, 1235–1236

Infectious diarrhea, 603–604

Infectious disease. See also specific diseases, e.g., Tuberculosis
cardiolipin antibody in, 114
gallium scan for, 636–638
renogram for, 1040–1042
sputum cytology for, 530–534
WBC and differential in, 400–403
white blood cell scan for, 1231–1233

Infectious enteritis, 274–276

Infectious hepatitis. See also Hepatitis
cold agglutinin titer levels in, 342–343
cryoglobulin detection in, 485–486
EBV-specific serology in, 742–744
GGT levels in, 670–672
lymph node biopsy for, 202–205
rheumatoid factor and, 1049–1050
screening for, 742–744
syphilis serology testing for, 1081–1083
viral culture for, 518–519
WBC and differential in, 400–403

Infectious process, 174–177

Infectious pulmonary disease, 951–954

Infertility. See also Fertility study
antisperm antibodies and, 108–110
Chlamydia antibody testing for, 304–306
semen analysis for, 1057–1059
uterine fibroid embolization and, 1199

Infiltrating lobular carcinoma, 1143–1147

Inflammation
abdominal angiography of, 58–61
bronchoscopy for, 250–253
colonoscopy for, 347–350
colposcopy for, 353–355
copper levels in, 462–463
cortisol and, 464
CRP assay for, 470–472
cystoscopy for, 524–526
electrocardiographic stress test for, 595–597
fibrinogen level in, 620–622
fluorescein angiography for, 623–625
gallium scan for, 636–638
LAP levels in, 795–797
lipase levels in, 797–799
liver and spleen scan for, 801–803
MRI for, 833–835, 855–857
mumps and, 883
percutaneous transhepatic cholangiography for, 315–318
prealbumin and, 983–984
RBC morphology in, 393–396
renal angiography in, 79–82
ultrasonography for, 1148–1149
upper GI series for, 1172–1174
white blood cell scan for, 1231–1233
Inflammatory bowel disease. See also
  Crohn’s disease; Ulcerative colitis
antineutrophilic cytoplasmic antibodies in, 103–104
cancer antigen levels in, 284–285
CRP assay for, 470–472
fecal analysis for, 603–604
gastrointestinal blood loss scan, 651–654
immunoglobulin E level in, 737–738
vitamin B₁₂ and, 1218–1219
vitamin D and, 1220–1222
white blood cell scan for, 1231–1233
Inflammatory disease, 712–714
alpha₁–antitrypsin levels in, 138–139
CRP assay for, 470–472
erythrocyte sedimentation rate and, 577–578
ferritin level in, 609–610
gallium scan for, 636–638
haptoglobin level in, 686–687
pulmonary angiography of, 74–77
RBC count in, 384–388
renogram for, 1040–1042
sputum cytology for, 530–534
urine cytology for, 534–536
WBC and differential in, 399–403
Influenza, WBC and differential in, 400–403
Inguinal hernia repair, 109–110
inhibin-A, dimeric, 614
Injury, 1028–1029
Inner ear malformation, 154–156
INR (International normalized ratio), 1007–1011
Intestinal disease, 712–714
alpha₁–antitrypsin levels in, 138–139
CRP assay for, 470–472
erthrocyte sedimentation rate and, 577–578
ferritin level in, 609–610
gallium scan for, 636–638
haptoglobin level in, 686–687
pulmonary angiography of, 74–77
RBC count in, 384–388
renogram for, 1040–1042
sputum cytology for, 530–534
urine cytology for, 534–536
WBC and differential in, 399–403
Intestinal infection
colonoscopy in, 347
proctosigmoidoscopy in, 985–988
Intestinal inflammation. See Crohn’s disease; Colitis; Enteritis; Inflammatory bowel disease; Ulcerative colitis
Intestinal lymphangiectasia, triglyceride levels in, 1110–1111
Intestinal malabsorption, vitamin B₁₂ in, 1218–1219
Intestinal obstruction
  abdominal laparoscopy and, 783
  KUB study for, 771–772
  upper GI series and, 1173
Intestinal perforation. See Perforated bowel
Intestinal resection
  D-xylose tolerance test and, 547–550
  vitamin D and, 1220–1222
Intoxication, alcohol, 544–547
Intra-abdominal bleeding, 782–785
  abdominal laparoscopy and, 783
  Intra-aortic balloon pump, chest x-ray and, 301–303
Insulin-dependent diabetes (type 1). See also Diabetes mellitus
  C-peptide levels in, 468
  insulin levels in, 745
  intrinsic factor antibody and, 759
  Insulin-induced hypoglycemia, 991–993
  Insulinoma, 659–662
  Insulin-resistant diabetes, 745
  Intact parathyroid hormone, 919–922
  Intermittent porphyria, acute. See Acute intermittent porphyria
Internal bleeding, 833–835
Internal scarring, 728–730
International normalized ratio (INR), 1007–1011
International Sensitivity Index (ISI), 1007
Interstitial cell-stimulating hormone (ICSH), 813–816
Interstitial pulmonary disease, 250–253
Intervertebral disk, herniated, 446–449, 571–572
electromyography for, 565–567
MRI for, 848–850
Intestinal atresia, ultrasonography for, 1136–1139
Intestinal biopsy, 188–190
Intestinal disease
  glucose tolerance test in, 666–669
  oxalate levels in, 910–912
  proctosigmoidoscopy in, 985–988
  Intestinal distention, colonoscopy in, 347–350
  Intestinal fistula, potassium levels and, 976–978
  Intestinal in
  colonscopy in, 347
  proctosigmoidoscopy in, 985–988
  Intestinal inflammation. See Crohn’s disease; Colitis; Enteritis; Inflammatory bowel disease; Ulcerative colitis
  Intestinal lymphangiectasia, triglyceride levels in, 1110–1111
  Intestinal malabsorption, vitamin B₁₂ in, 1218–1219
  Intestinal obstruction
    abdominal laparoscopy and, 783
    KUB study for, 771–772
    upper GI series and, 1173
  Intestinal perforation. See Perforated bowel
  Intestinal resection
    D-xylose tolerance test and, 547–550
    vitamin D and, 1220–1222
  Intoxication, alcohol, 544–547
  Intra-abdominal bleeding, 782–785
  abdominal laparoscopy and, 783
  Intra-aortic balloon pump, chest x-ray and, 301–303
Insulin C-peptide, 467
Intracellular parasite, 364, 392
Intracerebral hematoma, 417–420
Intracranial pressure
  brain CT of, 417–420
  EEG determining, 562–564, 563–564
Intraepithelial lesion/malignancy, 915
Intrahepatic abscess, 1148–1149
Intrahepatic biliary hypoplasia, 24–26
Intramural hematoma, 844–846
Intraocular muscle function, 750–752
Intraocular pressure (IOP), 752–755
Intraparenchymal hematoma, 837–839
Intrarenal hematoma, 79–82
Intrauterine device
  immunoglobulin E level in, 737–738
  MRI and, 833, 837, 841, 844, 848, 852, 856, 859
  placement of, ultrasonography for, 1156–1158
Intrauterine fetal death
  AFP levels in, 614
  fibrin degradation product and, 618–619
  human chorionic gonadotropin level in, 716–717
Intrauterine growth retardation, 792–795
Intravascular coagulation. See Disseminated intravascular coagulation (DIC)
Intravenous device, chest x-ray and, 301–303
Intravenous glucose infusion, 1066–1067
Intravenous overload, 374–378
Intravenous pyelography, 755–758
Intravenous therapy
  potassium levels and, 976–978
  sodium levels and, 1065–1067
Intrinsic factor antibody, 759–760
Intrinsic factor deficiency, 1218–1219
Intussusception, 157–159
Invasive carcinoma, 353–355
In-vivo antibody sensitization, 457–458
Iodinated dye(s)
  angiography and, 59, 63, 67, 71, 74, 79
  hysterosalpingography and, 728
  intravenous pyelography and, 756
  voiding cystourethrography and, 527
Iodine, excessive intake of, 1102–1104
Iodine uptake, 1021–1023
Iodine-deficiency goiter
  radioactive iodine uptake and, 1021–1023
  total triiodothyronine levels and, 1114–1116
Iodine-rich food product, 1022
IOM function, 750–752
Ion, 974
Ionized calcium, 264–267
Ionizing radiation, 874
Iridocorneal endothelial syndrome, 676–677
Iritis, 1062–1064
Iron (Fe), 609–610, 760–764
  ferritin and, 608
  hemosiderin and, 691
  transferrin and, 1106
Iron overload, transfusion related, 1272
Iron saturation, 764–766
Iron stain, 691
Iron storage granule, 691
Iron-binding capacity, total, 764–766
Iron-deficiency anemia
  copper levels in, 462–463
  ferritin level in, 609–610
  free erythrocyte protoporphyrin test for, 576–577
  iron level with, 762–764
  osmotic fragility and, 902–903
  platelet count in, 379–382
  RBC indices in, 390–391
  RBC morphology in, 393–396
  total iron-binding capacity and, 765–766
  transferrin level in, 1106–1108
Irrigation, venipuncture and, 1256–1257
Ischemia
  electrocardiogram for, 558–561
  exercise stress test for, 595–597
  Holter monitor and, 707–709
  MRI for, 843–846
  PET scan for, 967–970
  plethysmography for, 950–954
  transesophageal echocardiography of, 555–557
  ultrasonography for, 1129–1131
Ischemic heart disease
  myocardial perfusion heart scan for, 888–893
  total cholesterol level in, 330–333
  triglyceride levels and, 1109–1111
ISI (International Sensitivity Index), 1007
Islet cell tumor
  C-peptide levels in, 468–469
  glucose tolerance test for, 666–669
  MRI for, 852–854
Isoenzyme
  alkaline phosphatase and, 23–26
  creatine kinase and, 472–475
  lactate dehydrogenase and, 775–776
Isoflow volume, 1014
Isolation precautions
  for hospitals, 1277–1283
  of HICPAC, 1283–1284
Isopropyl alcohol, 767–770
Isospora belli infection, 908–909
Isotope Dilution Mass Spectrometry (IDMS), 481
IV. See Intravenous entries

J
Jaundice
  bilirubin levels in, 163–166
  CT in, 413, 430
  ERCP in, 322
  GGT levels in, 670
  hemolytic, 163–166
  hepatic, 164–166
  hepatitis A virus and, 693
  lactate dehydrogenase levels in, 775–776
  laparoscopic evaluation of, 782
  liver-spleen scan in, 801
  obstructive, 670, 775, 1225
  percutaneous transhepatic cholangiography for, 315–318
  prehepatic, 163–166
  ultrasonography for, 1148
  vitamin K and, 1225–1226
Jejunal shunt, 910–912
Jo-1 antibody, 104–108
Joint(s). See also Arthritis; Rheumatoid arthritis
  degenerative disease of, 147–149, 1078–1080
  derangement/dislocation of arthrogram in, 144–146
  radiography in, 1028–1029
  effusion in, radiography for, 1028–1029
  MRI of, 847–850
  pain in
    arthroscopy for, 146
    bone scan for, 246
    Lyme disease and, 816
  tumor of
    arthroscopy for, 147–149
    synovial fluid analysis in, 1078–1080
  Joint fluid analysis, 1077–1080
  Juvenile dermatomyositis, 357–358
  Juvenile rheumatoid arthritis, 721–722

K
Kallmann's syndrome, 815–816
Karyotype
  amniotic fluid analysis and, 48
  chorionic villus biopsy for, 185
  Kawasaki disease, 254–255

L
Laboratory test(s)
  for auditory system, 1237
  for cardiovascular system, 1237
  for drug therapy monitor and toxicology, 1249–1250
  for endocrine system, 1238–1239
Laboratory test(s) (continued)

- for gastrointestinal system, 1239–1240
- for genitourinary system, 1240–1241
- for hematopoietic system, 1241–1242
- for hepatobiliary system, 1243
- for immune system, 1244–1245
- for musculoskeletal system, 1246
- for nutritional consideration, 1247
- for oculomotor system, 1247
- for reproductive system, 1248
- for respiratory system, 1249
- natural products affecting, 1274–1276
- nursing diagnoses associated with, 1264
- patient preparation for, 1251
- Laceration, splenic, CT of, 404, 450
- Lactase, 779
- Lactate dehydrogenase, 775–776
- Lactation
  - magnesium level and, 823–824
  - vitamin B₆ and, 1228
- Lactic acid, 776–779
- Lactic acidosis, 84–86
  - lactic acid levels and, 777–779
  - phosphorus levels in, 940–942
  - sodium levels in, 1065–1067
  - uric acid level in, 1186–1188
- Lactogenic hormone, 990
- Lactose, 779
- Lactose intolerance, 780
  - amino acid levels in, urine test for, 40
  - intestinal biopsy for, 188–190
- Lactose tolerance test, 779–781
- LAP (leukocyte alkaline phosphatase), 795–797
- Laparoscopy
  - abdominal, 782–785
  - gynecologic, 785–788
- Laron dwarfism, 683–684
- Laryngospasm, 555
- Laser ablation, 917
- LASIK surgery, 913
- Lassa virus, 518–519
- Latex allergy, 27–28, 789
- Laxative abuse
  - aldosterone levels in, 20–22
  - magnesium level and, 823–824
  - potassium levels and, 976–978
- LDLC (low-density lipoprotein cholesterol), 325–329
- Lead, 789–791
- Lead encephalopathy, 790
- Lead mobilization test, 790–791
- Lead poisoning
  - D-aminovaleric acid levels in, 41–43
  - free erythrocyte protoporphyrin test for, 576–577
  - uric acid level in, 1186–1188,
    1189–1191
  - Lecithin/sphingomyelin ratio, 791–795
- LEEP procedure, 182–185
- Left atrial hypertension, 805–807
- Left bundle branch block, 595–597
- Left ventricle aneurysm, 886
- Left ventricle enlargement/hypertrophy
  - myocardial perfusion heart scan for, 890
  - natriuretic peptide in, 254
  - PET scan for, 967–970
- Legg-Calvé-Perthes disease
  - bone scan for, 245–248
  - MRI for, 848–850
- Legionella spp.
  - culture for, 502, 512–514
  - lung biopsy for, 198–201
- Leiomyoma, 1156–1158
- Leishmaniasis, 1049–1050
- Lens disorders, 676–677
- Leprosy, 261–263
  - angiotensin-converting enzyme in, 82–83
  - Mycobacterium fortuitum, 488
  - protein level in, 996–998
  - rheumatoid factor and, 1049–1050
  - syphilis serology testing for, 1081–1083
- Leptospirosis, 1081–1083
- Lesch-Nyhan syndrome, 1186–1188
- Leucine, 40–41
- Leucine crystal, 1196
- Leukemia
  - aldolase levels in, 18–19
  - amino acid levels in, urine test for, 40
  - beta₂-microglobulin levels in, 880–883
  - bone marrow biopsy for, 174–177
  - calcium values in, 260–263
  - cerebrospinal fluid (CSF) levels in, 299–300
  - chronic granulocytic, 1218–1219
  - copper levels in, 462–463
  - cryoglobulin detection in, 485–486
  - ferritin level in, 609–610
  - hemoglobin electrophoresis and, 689–691
  - hemoglobin in, 374–378
  - human T-lymphotropic virus antibodies and, 722–724
  - immunoglobulin E level in, 737–738
  - lactate dehydrogenase levels in, 775–776
  - LAP levels in, 795–797
  - lymph node biopsy for, 202–205
  - platelet antibody and, 948–949
  - platelet count in, 379–382
  - pyruvate kinase levels in, 1020

Davis’s Comprehensive Laboratory and Diagnostic Handbook—With Nursing Implications
INDEX

RBC count in, 384–388
RBC morphology in, 393–396
Schirmer tear test for, 1055–1056
uric acid level in, 1189–1191
urinary calcium levels in, 268–271
urine creatinine clearance test and, 482–484
vitamin B₁₂ and, 1218–1219
WBC and differential in, 399–403
Leukocyte, 1195
Leukocyte alkaline phosphatase (LAP), 795–797
Leukocytoclastic skin vasculitis, 103–104
Leukocytosis, 397, 398
potassium levels and, 975–978
vitamin B₁₂ and, 1218–1219
Leukopenia, 397, 400–403
Leukoplakia, 353–355
Leydig cell, 1084
LH (luteinizing hormone), 814–816
Licorice, excessive ingestion of, 976–978
Lidocaine, 86–92
Lifestyle
 cardiac scoring for, 421–424
creatine kinase and, 474–475
Ligament
 arthrogram of, 143–146
arthroscopy of, 147–149
Light, as source of interference with
pulse oximetry, 1019
Limb girdle muscular dystrophy, 18–19
Linen and laundry, 1282
Lipase, 797–799
Lipemic specimen, 811
Lipid emulsion therapy, 1019
Lipid metabolism, 140–143
Lipoid ovarian tumor, 989–990
Lipoid pneumonia, 530–534
Lipoma, 837–839
Lipoprotein deficiency, 141–143
Lipoprotein electrophoresis, 799–800
Listeria, 494–497
Lithium, 131–134
thyroid antibody levels in, 112–113
thyroid-stimulating immunoglobulin and, 1096–1097
Liver
acetylcholinesterase in, 1030
computed tomography of, 412–416
C-reactive protein and, 470–472
iron storage in, 764–765
lactic acid in, 776–779
MRI of, 832–835
prealbumin and, 983–984
protein C and, 999
protein synthesizing/catabolizing in, 1004
radiofrequency ablation of,
1024–1027
transferrin formation in, 1106–1108
trauma to, KUB study for, 771–772
ultrasonography of, 1147–1149
Liver and spleen scan, 800–803
Liver biopsy, 194–197
Loffler's syndrome, 573–575
Long-acting thyroid stimulator, 1095
Loop electrosurgical excision procedure (LEEP), 917
Loose body, 147–149
Lordosis, 1016–1017
Low birth weight, 615–617
Low-density lipoprotein cholesterol (LDLC), 325–329
Lower abdominal ultrasound, 1155–1158
Lower endoscopy, 346–350
Lower gastrointestinal cancer, 737–738
Lower limb venography, 1207
Lower motor neuron, 565–567
Lower panendoscopy, 346–350
Lowe's syndrome, 40
Lumbar spondylosis, 446–449
Lumpectomy, 840
Lung. See also Pulmonary entries
acetylcholinesterase in, 1030
chest x-ray of, 301–303
displacement of, 805–807
hyperinflation of, 555–557
injury to, transfusion-related,
1270–1271
Lung biopsy, 197–201
Lung cancer
alkaline phosphatase levels in, 24–26
beta₂-microglobulin levels in, 880–883
bronchoscopy for, 250
calcitonin stimulation test for,
257–259
calcium values in, 261–263
ceruloplasmin levels in, 299–300
cortisol levels in, 465–467
FDG-PET scan for, 599–601
human chorionic gonadotropin level in, 716–717
pulmonary function study in,
1012–1017
sputum cytology for, 530–534
Lung CK-BB, 473–474
Lung perfusion scan, 804–807
Lung perfusion scintigraphy, 804–807
Lung scintiscan, 804–807
Lung ventilation scan, 807–810
Lung volume, 1012–1017
Lupus anticoagulant antibody (LA), 811–813
Lupoid hepatitis, 106–108
Lupus erythematosus
discoid, 212–214
disseminated, 191–194, 400–403
systemic. See Systemic lupus erythematosus (SLE)
Luteinizing hormone (LH), 813–816
Luteotropic hormone, 990
Luteotropin, 813
Lycine, 40–41
Lyme antibody, 816–818
Lyme disease, 816, 1082–1083
Lymph node
biopsy of, 202–205
chest x-ray for enlargement of, 302–303
infectious mononucleosis and, 742–744
thoracic CT for, 454–456
ultrasonography of, 1150–1152, 1164–1166
Lymphadenoma, 175–177
Lymphangiography, 818–821
Lymphangiitis, 202–205
Lymphatic disease, 1164–1166
Lymphatic fistula, 16–18
Lymphatic leukemia, 174–177
Lymphatic system, 818–821
Lymphatic vessel, abnormal, 819–821
Lymphoblastic leukemia
human T-lymphotropic virus antibodies and, 722–724
LAP levels in, 795–797
Lymphocytes, 291–293, 398
Lymphocytic choriomeningitis virus, 518–519
Lymphocytic leukemia
beta-2-microglobulin and, 879
cryoglobulin detection in, 485–486
WBC and differential in, 400–403
Lymphocytopenia, 400–403
Lymphogranuloma venereum
lymph node biopsy for, 202–205
Pap smear and, 917
syphilis serology testing for, 1081–1083
Lymphoma. See also specific types, e.g., Hodgkin’s disease
beta-2-microglobulin levels in, 880–883
bone marrow biopsy for, 174–177
calcium values in, 260–263
cryoglobulin detection in, 485–486
D-xylene tolerance test for, 547–550
erythrocyte sedimentation rate and, 577–578
FDG-PET scan for, 599–601
gallium scan for, 636–638
immunoglobulin E level in, 737–738
lymph node biopsy for, 202–205
lymphangiography for, 819–821
platelet count in, 379–382, 380–382
RBC morphology in, 393–396
Schirmer tear test for, 1055–1056
ultrasonography for, 1150–1152
urinary calcium levels in, 268–271
vitamin D and, 1220–1222
WBC and differential in, 400–403
Lymphosarcoma
bone marrow biopsy for, 174–177
erthrocyte sedimentation rate and, 577–578
uric acid level in, 1189–1191
M
MAA (macroaggregated albumin), 804–807
Macroadenoma, 858–861
Macroaggregated albumin (MAA), 804–807
Macroamylasemia, 52–53
Macro-CK, 473–474
Macrocyte, 363, 392
Macrocytic anemia, 389–391
Macroglobulin, 738
Macroglobulinemia, 174–177. See also Waldenstrom’s macroglobulinemia
Macrophage, 734
Macular degeneration
fluorescein angiography for, 623–625
fundus photography for, 634–635
visual field test for, 1215–1217
Macular drusen, 1215–1217
Magnesium
in blood specimen, 822–824
in urine specimen, 825–828
Magnesium deficiency, 823–824
alkaline phosphatase levels in, 25–26
ionized calcium values in, 265–267
Magnetic resonance angiography (MRA), 829–831, 836–839
of pancreas, 851
of pelvis, 855
Magnetic resonance imaging (MRI)
of abdomen, 832–835
of brain, 836–839
of breast, 839–843
of chest, 843–846
of musculoskeletal system, 847–850
of pancreas, 851–854
of pelvis, 854–857
of pituitary area, 858–861
Major depression, 126–128
Major histocompatibility complex, 720
Malabsorption
albumin/globulin ratio, 16–18
amino acid levels in, blood test for, 37–38
aPTT in, 926–929
copper levels in, 462–463
D-xylose tolerance test for, 547–550
folate level in, 627–628
magnesium level and, 823–824
potassium levels and, 976–978
protein level in, 996–998
radioactive iodine uptake and, 1022–1023
total cholesterol level in, 331–333
urinary calcium levels in, 269–271
vitamin B₆ and, 1227, 1228
vitamin C and, 1228
zinc level in, 1235–1236
Malabsorption syndrome
BUN level in, 1178–1180
fecal analysis for, 603–604
fecal fat and, 605
gastric emptying scan for, 642–645
glucose levels in, 659–662
phosphorus levels in, 940–942
sodium levels and, 1068–1071
triglyceride levels and, 1110–1111
vitamin B₁₂ and, 1218–1219
vitamin C and, 1227
vitamin D and, 1220–1222
vitamin E and, 1222–1224
Malaria
bacterial culture for, 498–501
cold agglutinin titer levels in, 342–343
osmotic fragility and, 902–903
platelet count in, 380–382
rheumatoid factor and, 1049–1050
syphilis serology testing for, 1082–1083
WBC and differential in, 399–403
Malignant hypertension, 1036–1039
Malignant hyperthermia
myoglobin levels in, 894–895
skeletal muscle CK-MM and, 474–475
Malignant melanoma, 212–214
Malignant ocular neoplasm in angle, 676–677
Mallory-Weiss syndrome
capsule endoscopy for, 274–276
esophagogastroduodenoscopy for, 586–589
fecal analysis for, 603–604
Malnutrition, 261–263. See also Starvation
albumin/globulin ratio, 16–18
alpha₁-antitrypsin levels in, 138–139
amino acid levels in, blood test for, 37–38
apolipoprotein B and, 141–143
calcitonin stimulation test for, 257–259
ceruloplasmin levels in, 299–300
copper levels in, 462–463
cystoscopy for, 523–526
eosinophil count in, 573–575
fibrinogen level in, 620–622
haptoglobin level in, 686–687
immunoglobulin E level in, 737–738
intestinal biopsy for, 188–190
kidney biopsy for, 191
liver biopsy for, 190–197
lung biopsy for, 198–201
lymph node biopsy for, 202–205
MRI for, 855–857
pericardial fluid analysis for, 932–934
peritoneal fluid analysis for, 935–938
pleural fluid analysis and, 956–958
protein levels in, 1004–1006
syphilis serology testing for, 1082–1083
thyroid scan for, 1090–1092
transferrin level in, 1106–1108
ultrasonography for, 1140–1141, 1143–1147, 1162–1163
urine cytology for, 218–219
vitamin C and, 1228
WBC and differential in, 399–403
Malnutrition (continued)
protein level in, 996–998
pseudocholinesterase level in, 1012
radiography for, 1028–1029
RBC count in, 384–388
RBC indices in, 389–391
TBG level in, 1098–1099
testosterone and, 1085–1086
total cholesterol level in, 330–333, 331–333
transferrin level in, 1106–1108
triglyceride levels and, 400–403
vitamin B₁₂ and, 1218–1219
WBC and differential in, 399–403
zinc level in, 1234–1236

Mammography, 861–864
MRI and, 840
stereotactic biopsy and, 1074
ultrasonography and, 1142

Man
follicle-stimulating hormone level in, 628
prolactin level in, 990

Manic depression, 131–134, 287–290

Manometry
esophageal, 582–585
Mantoux test, 301–303, 1119, 1121
Maple syrup urine disease
amino acid levels in, urine test for, 40
glucose levels in, 659–662
Marburg virus, 518–519
Masculinization, 542
Masks, 1280–1281

Mass
MRI for, 833–835, 855–857
PET scan for, 963–966
renogram for, 1040–1042
ultrasonography for, 1156–1158, 1161–1163, 1164–1166

Mast cell, 733
Mastectomy, 840
Mastitis, 862–864
Mastocytosis, 725–726
Maternal diabetes, 792–795
Maximal inspiratory-expiratory pressure, 1014
Maximal midexpiration flow, 1013
Maximal voluntary ventilation, 1013–1017
May-Hegglin anomaly, platelet count and, 380–382
MB (myoglobin), 764–765, 893–895
MCH (mean corpuscular hemoglobin), 388–391
MCHC (mean corpuscular hemoglobin concentration), 388–391
MCV (mean corpuscular volume), 388–391
Mean corpuscular hemoglobin (MCH), 388–391
Mean corpuscular hemoglobin concentration (MCHC), 388–391
Mean corpuscular volume (MCV), 388–391
Mean platelet volume (MPV), 379
Measles virus
rubeola antibody and, 1053
syphilis serology testing for, 1081–1083
viral culture for, 517–519
Meckel's diverticulum scan, 864–867
Mediastinal tumor, 302–303
Mediastinoscopy, 868–871
Mediastinum, 868–871
Medications. See Drug(s)
Medullary carcinoma, 1143–1147
Medullary thyroid cancer, 257–259
Megakaryocytic hypoproliferation, 380
Megakaryocytic myelosis, 174–177
Megaloblastic anemia, 1031–1032
folic acid level in, 627–628
hemoglobin electrophoresis for, 689–691
hemosiderin levels in, 692–693
intrinsic factor antibody and, 759–760
lactate dehydrogenase levels in, 775–776
platelet count in, 380–382
RBC morphology in, 394
vitamin B₁₂ and, 1218–1219
WBC and differential in, 399–403
Melanin pigment, 461
Melanoma
FDG-PET scan for, 599–601
skin biopsy for, 212–214
Membrane rupture, premature
amniotic fluid analysis in, 46
fetal fibronectin in, 611
L/S ratio in, 791
ultrasound biophysical profile in, 1136
Membranous glomerulonephritis, 357–358
complement protein levels in, 359–360
MEN 2A syndrome, 261–263
MEN type II, 257–259
Meningioma
MRI for, 837–839, 859–861
pituitary CT of, 437–441
Meningitis
bacterial culture for, 500–501
cerebrospinal fluid analysis for, 295–298
complement protein levels in, 357–358
EEG determining, 563–564
viral culture for, 518–519
Meningocele, spine CT in, 446
Meniscal disease, arthroscopy in, 147–149
Meniscal tear/laceration
  arthrogram of, 144–146
  MRI for, 848–850
Menkes disease
ceruloplasmin levels in, 299–300
copper levels in, 462–463
Menopause
  follicle-stimulating hormone level in, 629–631
  luteinizing hormone secretion and, 815–816
  osteoporosis and, 344
  prolactin level during, 990
Menorrhagia
  aPTT in, 926–929
  prothrombin time and, 1008–1011
Menstruation. See also Amenorrhea
  ACTH levels in, 10
  cancer antigen levels in, 284–285
  erythrocyte sedimentation rate and, 577–578
  follicle-stimulating hormone levels during, 630
  hysterosalpingography and, 728
Mental retardation, 48–51
Mercury poisoning, 880–883
Mesenteric lymphadenopathy, 426–429
Metabolic acidosis
  anion gap for, 83–86
  blood gas analysis in, 225, 227
  carbon dioxide levels in, 277–279
  chloride values in, 308–310
Metabolic alkalosis
  blood gas analysis in, 225, 227
  carbon dioxide and, 277
  chloride values in, 308–310
Metabolic complication, transfusion related, 1271
Metabolic disorder
  vitamin C and, 1227
  WBC and differential in, 400–403
Metabolic disturbance, 1028–1029
Metabolic syndrome
  CRP assay for, 471–472
  glucose levels in, 659–662
  HDLc and LDLc levels in, 326–329
  total cholesterol level in, 331–333
  triglyceride levels and, 1109–1111
Metabolism, 768
Metachronous lesion, 426–429
Metal, x-ray-absorbing, 1027–1029. See also Metallic objects
Metal toxicity
  ESR and, 577–580
  lead and, 790
  porphyrin levels in, 960–962
  protein levels in, 1004–1006
Metallic objects
  abdominal laparoscopy and, 783
  FDG-PET scan imaging and, 599
  gastric emptying scan and, 645
  gastroesophageal reflux scan and, 649
  gastrointestinal blood loss scan, 652
  gynecologic laparoscopy and, 786
  hepatobiliary scan and, 702
  hysterosalpingography and, 728
  intravenous pyelography and, 756
  KUB study and, 771
  liver and spleen scan, 802
  lung perfusion scan and, 805
  lung ventilation scan and, 808
  lymphangiography and, 819
  mammography and, 863

  MRI and, 833, 837, 840–841, 844, 848, 852, 855, 859
  myocardial infarction scan and, 886
  myocardial perfusion heart scan and, 890–891
  parathyroid scan and, 923
  PET scan and, 964, 967, 971
  radioactive iodine uptake and, 1022
  radiofrequency ablation and, 1025
  radiography and, 1028
  renogram and, 1040
  retrograde ureteropyelography and, 1046
  retrograde urethrogram and, 1184
  stereotactic biopsy and, 1075
  thyroid scan and, 1091
  ultrasonography and, 1130, 1137, 1140, 1143, 1146, 1148, 1151, 1153, 1156, 1159, 1162, 1164, 1167
  upper GI series and, 1173
  uterine fibroid embolization and, 1200
  venogram and, 1208
  vertebroplasty and, 1212
  white blood cell scan and, 1231
Metanephrine, 871
Metastasis
  abdominal CT of, 404–407
  bone marrow biopsy for, 174–177
  chest x-ray and, 301–303
  colonoscopy for, 426–429
  FDG-PET scan for, 599–601
  kidney CT for, 442–445
  liver and spleen scan for, 801–803
  lymph node biopsy for, 202–205
  lymphangiography for, 819–821
  MRI for, 837–839, 852–854, 859–861
  myocardial infarction scan and, 886
  Pap smear and, 917
  pelvic CT of, 433–437
Metastasis (continued)
PET scan for, 971–973
phosphorus levels in, 939–942
pituitary CT of, 437–441
radioactive iodine uptake and, 1022–1023
splenic CT of, 450–453
thyroid scan for, 1090–1092
ultrasonography for, 1148–1149, 1155–1158
Metastatic bone cancer
osteocalcin levels in, 904–905
scan for, 4, 245–248
Metastatic carcinoma
platelet count in, 380–382
RBC morphology in, 393–396
Methanol intoxication, 544–547
Methemoglobin, 874–876
Methemoglobinemia, 874–876
Methicillin resistant Staphylococcus aureus, 494–497
Methionine, 40–41, 709
Methotrexate, 739–742
Methylglucamine, 872
1–Methylhistine, 40–41
3–Methylhistine, 40–41
Methylmalonic acid, 709–711
Methylmalonic aciduria, 767–770
Metyrapone stimulation test, 7–12, 464–467
MG. See Myasthenia gravis (MG)
Microadenoma, 858–861
Microalbumin, 876–879. See also Albumin (Alb)
Microalbuminuria, 876
Microaneurysm, 623–625
Microangiopathic hemolytic anemia, 692–693
Microcyte, 363, 392
Microcytic anemia, 461
beta2–Microglobulin, 880–883
Microhemagglutination, T. pallidum, 1081
MRA. See Magnetic resonance angiography (MRA)
MRI. See Magnetic resonance imaging (MRI)
Mucopolysaccharidosis, 312–314
Mucosal damage, 606
Mucus plug, 30–32
Multiple dystrophy, 566–567
Multiple gestation, 792–795
Multiple myeloma
amino acid levels in, urine test for, 40
beta2–microglobulin levels in, 880–883
cold agglutinin titer levels in, 342–343
cryoglobulin detection in, 485–486
erthrocyte sedimentation rate and, 577–578
fibrinogen level in, 620–622
immunofixation electrophoresis for, 731
immunoglobulin E level in, 736–738
intravenous pyelography and, 756
LAP levels in, 795–797
protein levels in, 1004–1006
RBC count in, 384–388
retrograde ureteropyelography and, 1046
syphilis serology testing for, 1082–1083
uric acid level in, 1186–1188, 1189–1191

Multiple sclerosis
brain CT of, 417–420
cerebrospinal fluid analysis for, 295–298
evoked brain potentials in, 591–594
fecal fat and, 606–608
MRI for, 837–839
Multipuncture test, 1118

Mumps
amylase levels in, 52–53
pancreatitisis and, 658
semen analysis and, 1058–1059
syphilis serology testing for, 1081–1083
Mumps serology, 883–885

Muscle
electromyography of, 565–567
electroneurography of, 570–572
Muscle biopsy, 205–208
Muscle injury
alanine aminotransferase levels in, 13–15
arthrogram of, 144–146
Muscle mass
blood creatinine clearance test and, 478–479
creatine kinase and, 474–475
urine creatinine clearance test and, 482–484
Muscle necrosis, 975–978
Muscle relaxants
electromyography and, 566
sphincter muscle electromyography and, 568–570
Muscle wasting disease
aldolase levels in, 18–19
BUN level in, 1178–1180
urine creatinine clearance test and, 482–484
Muscular dystrophy
alanine aminotransferase levels in, 13–15
aldolase levels in, 18–19
amino acid levels in, urine test for, 40
aspartate aminotransferase levels in, 150–152
blood creatinine clearance test and, 478–479
electromyography for, 565–567
electroneurography for, 571–572
muscle biopsy for, 205–208
myoglobin levels in, 894–895
pseudocholinesterase level in, 1012
pyruvate kinase levels in, 1020
skeletal muscle CK-MM and, 474–475
Musculoskeletal disease, 775–776
Musculoskeletal system
laboratory and diagnostic tests for, 1246
MRI of, 847–850
Myasthenia gravis (MG), 1
electromyography for, 566–567
electroneurography for, 571–572
muscle biopsy for, 205–208
myoglobin levels in, 894–895
pulmonary function study for, 1016–1017
Mycobacteria culture/smear, 487–492
Mycobacterial infection, 500–501
Mycobacterium avium intracellulare, 487–488
Mycobacterium culture and smear, 487
Mycobacterium fortuitum, 488
Mycobacterium kansasii, 488
Mycobacterium leprae, 488
Mycobacterium marinum, 488
Mycobacterium tuberculosis, 487–488. See also Tuberculosis
Mycobacterium xenopi, 488

Mycoplasma pneumoniae, 457
cold agglutinin titer levels and, 341–343
syphilis serology testing for, 1081–1083
Mydriatics
fundus photography and, 634
refraction and, 1033
slit-lamp biomicroscopy and, 1063

Myelocele, 446–449
Myelocytic leukemia, 400–403
Myelofibrosis
bone marrow biopsy for, 174–177
folate level in, 627–628
LAP levels in, 795–797
platelet count in, 380–382
RBC morphology in, 393–396
Myelogenous leukemia, 796–797

Myeloid leukemia
bone marrow biopsy for, 174–177
platelet antibody and, 948–949

Myeloid metaplasia, 795–797

Myeloma
apolipoprotein B and, 141–143
calcium values in, 260–263
FDG-PET scan for, 599–601
hexosaminidase level in, 705–706
immunoglobulin E level in, 734–735
LDLC level in, 327–329
protein level in, 996–998
radiography for, 1028–1029
RBC morphology in, 393–396
total cholesterol level in, 331–333
urinary calcium levels in, 268–271
WBC and differential in, 400–403
Myelomeningocele, 1136–1139
Myeloproliferative disorder
  bleeding time in, 220
eosinophil count in, 573–575
  hemoglobin electrophoresis and, 689–691
Myocardial infarction, 254–255
  alanine aminotransferase levels in, 13–15
  aldolase levels in, 18–19
  WBC and differential in, 400–403
Myotonia congenita, 205–208
Myotonic dystrophy, 1085–1086
Myxedema, 640–642
Myxoma
  echocardiography for, 551–554
  transesophageal echocardiography of, 554–557

N
N-Acetyl procainamide, 86–92
Nails, fungal culture of, 515–516
Narcolepsy, 563–564
Narcotic addiction. See Drug abuse
Narrow-angle glaucoma

Neonatal immune thrombocytopenia, 948–949
Neonatal lupus, 106–108
Neonatal prematurity, 261–263
copper levels in, 462–463
ionized calcium values in, 265–267
Neonatal seizure, 1228
Neonate. See Neonatal entries and Newborn
Neoplasms. See Tumor(s), particular tumor types, and site-specific entries
Neoplastic disease. See specific conditions
Neovascularization
fluorescein angiography for, 623–625
gonioscopy for, 676–677
Nephritis, 106–108, 742–744. See also Glomerulonephritis
chloride values in, 308–310
erthrocyte sedimentation rate and, 577–578
iron level in, 762–764
renin value in, 1036–1039
Nephroblastoma, 581–582
Nephrogenic diabetes insipidus
antidiuretic hormone and, 129–130
sweat chloride values in, 312–314
Nephrolithiasis. See Renal calculi
Nephropathy. See also Kidney disease
microalbumin and, 877–879
protein levels in, 1004–1006
renin value in, 1036–1039
Nephrosis
iron level in, 762–764
urinary calcium levels in, 269–271
Nephrotic syndrome, 129–130
tamosterone levels in, 20–22
alpha1-antitrypsin levels in, 138–139
amino acid levels in, blood test for, 37–38
antithrombin III levels in, 135–136
apolipoprotein A and, 141–143
apolipoprotein B and, 141–143
copper levels in, 462–463
fibrinogen level in, 620–622
HDLC and LDL levels in, 326–329
hyperlipoproteinemia and, 799–800
immunoglobulin E level in, 737–738
kidney biopsy for, 191–194
protein level in, 996–998, 1004–1006
pseudocholinesterase level in, 1011–1012
sodium levels and, 1066–1067
TBG level in, 1098–1099
total cholesterol level in, 330–333
total thyroxine level and, 1102–1104
triglyceride levels and, 1109–1111
zinc level in, 1235–1236
Nephrotoxic agent, 1178–1180
Nerve fiber analysis, 896–898
Nerve transection, 570
Neural tube defect
AFP levels in, 613–617
amniotic fluid analysis for, 47–51
Nerulalgia, trigeminal, 119
Neuritis
optic, 1215–1217
retrobulbar, 591–594
Neuroblastoma
catecholamine levels in, 287–290
homovanillic acid level in, 712–714
metanephrine levels and, 872–873
vanillylmandelic acid level in, 1203–1205
Neurofibroma, skin biopsy for, 212–214
Neurogenic bladder
cystometry and, 520–523
voiding cystourethrography for, 527–529
Neurogenic pain, 119
Neuromuscular dysfunction
  human T-lymphotropic virus antibodies and, 722–724
  sphincter muscle electromyography and, 568–570
  vitamin E and, 1222–1224
Neuromuscular junction, 565–567
Neuromuscular junction testing, 565–570
Neuropathy

iron level in, 762–764
vitamin A and, 1228
vitamin B12 and, 1218–1219
Protein S, 1001–1003
Protein-losing enteropathy, 996–998
Proteus, 494–497, 512–514
Proteus spp., 494–497
Prothrombin, 1224
Prothrombin time, 1007–1011
Protoporphyria, 575
Prototoporphyri, 575
Provider-performed microscopy, 1273
Prussian blue stain, 691–693
PSA (prostate-specific antigen), 993–995
Pseudoaneurysm, 1129–1131
Pseudocholinesterase, 1011–1012, 1030
Pseudocyst
amylose levels in, 52–53
lipase levels in, 797–799
pancreatic CT of, 429–433
ultrasonography for, 1153–1154
Pseudogout
arthroscopy of, 147–149
parathyroid hormone levels in, 921–922
synovial fluid analysis and, 1078–1080
Pseudohypoparathyriodism
calcitonin stimulation test for, 257–259
ionized calcium values in, 265–267
parathyroid hormone levels in, 921–922
phosphorus levels and, 943–945
phosphorus levels in, 940–942
urinary calcium levels in, 269–271

Pseudomonas, 512–514
Pseudomonas aeruginosa
  bacterial culture for, 494–497
  bacterial pneumonia and, 502
Pseudomyxoma peritonei, 855–857
Pseudopregnancy, 615–617
Psittacosis, 1081–1083
Psoriasis
  DHEAS and, 542–543
  uric acid level in, 1186–1188
Psoriatic arthritis, 721–722
Psychiatric illness, 1102–1104
Psychogenic polydipsia, 129–130
Psychosis
  aldolase levels in, 18–19
  DHEAS and, 542–543
  evoked brain potentials in, 591–594
  FDG-PET scan for, 598–601
  PET scan for, 963–966
Ptosis of eye, 1215–1217
Puberty, 629–631, 1084
Pulmonary. See also Lung entries
Pulmonary angiography, 74–77
Pulmonary artery abnormality
  coronary angiography of, 70–73
  MRI for, 844–846
Pulmonary artery agenesis
  MRI for, 844
Pulmonary atresia, 844–846
Pulmonary carcinoma. See also Lung cancer
  angiotensin-converting enzyme in, 83
cancer antigen levels in, 284–285
Pulmonary compliance, 950, 951, 1015
Pulmonary disability, 1015–1017
Pulmonary disease. See also specific conditions, e.g., Pneumonia
  apolipoprotein B and, 141–143
  bronchoscopy for, 250–253
  calcium values in, 260
  chest x-ray and, 301
  chronic obstructive. See Chronic obstructive pulmonary disease (COPD)
  LDLC level in, 327–329
  lung biopsy for, 198
  lung perfusion scan in, 804
  plethysmography for, 951–954
  proctosigmoidoscopy and, 986
  pulmonary function study for, 1015–1017
  sputum cytology in, 530
  sweat chloride values in, 311
total cholesterol level in, 331–333
ZZ deficiency in, 137
Pulmonary drug regimen, pulse oximetry and, 1018
Pulmonary edema, 30–32
  A/a gradient and a/A ratio in, 30
  blood gas analysis in, 226–232
  PET scan and, 967
  skeletal muscle CK-MM and, 474–475
Pulmonary effusion
  lung perfusion scan in, 804
  lung ventilation scan in, 808
Pulmonary embolism, 30–32
  A/a gradient and a/A ratio in, 30
  alkaline phosphatase levels in, 25–26
  antithrombin III levels in, 135–136
  blood gas analysis in, 226–232
  D-dimer and, 539
  erythrocyte sedimentation rate and, 577–578
  fibrin degradation product and, 618–619
  lactic acid levels and, 777–779
  lung perfusion scan for, 805–807
  lung ventilation scan for, 807–810
  phosphorus levels in, 940–942
  proctosigmoidoscopy and, 986
  pulmonary angiography of, 74–77
  skeletal muscle CK-MM and, 474–475
  thoracic CT for, 454–456
  ultrasonography for, 1169
  venography of, 1208
Pulmonary eosinophilia, 573–575
Pulmonary failure, 777–779
Pulmonary fibrosis, 30–32
  A/a gradient and a/A ratio in, 30
  angiotensin-converting enzyme in, 83
  chest x-ray for, 302–303
  erythropoietin level in, 581–582
  pulmonary function study for, 1016–1017
Pulmonary function study, 1012–1017
Pulmonary hemosiderosis, 99–100
Pulmonary hypertension, 254–255, 805–807
Pulmonary infarction
  alkaline phosphatase levels in, 25–26
  aspartate aminotransferase levels in, 150–152
  electrocardiogram for, 559–561
  lactate dehydrogenase levels in, 775–776
  pleural fluid analysis and, 956–958
Pulmonary infection
  bronchoscopy for, 250–253
  Mycobacterium avium intracellulare in, 488
  Mycobacterium tuberculosis in. See Pulmonary tuberculosis
Pulmonary infection (continued)
plethysmography for, 951–954
sweat chloride values in, 311–314

Pulmonary neoplasm. See also Lung cancer
amylase levels in, 52–53
chest x-ray for, 301–303
function study and, 1016–1017
growth hormone levels and, 683–684
Pulmonary scan, 804–807

Pulmonary sequestration, 74–77

Pulmonary tuberculosis
antidiuretic hormone and, 129–130
growth hormone and, 1055–1056
pleural fluid analysis and, 956–958
zinc level in, 1235–1236

Pulse oximetry, 1018–1020
Punch biopsy, 182–185, 212–214
Pupil dilation, 1033

Purine, 1186–1188, 1189–1191
Purkinje fiber, 558

Pyelography, intravenous, 755–758

Pyothorax
BUN level in, 1178–1180
tuberculosis, 1190–1192

Pyelonephritis
BUN level in, 1178–1180
growth hormone levels and, 1016–1017

Pyloric obstruction, 645–647
Pyloric stenosis, 274–276

Pyrobole, 1161–1163

Pyridoxylic acid, 1226

Pyridoxine deficiency, 910–912

Pyrophosphate (PYP) cardiac scan, 750–752

Pyrophosphate (PYP) uptake, 885

Pyroxyline, 1226

Pyruvate kinase (PK), 1020

Pyruvate kinase deficiency, 902–903

QRS complex, 559–561

Quad-marker testing, 613, 715

QuantiFERON-TB Gold (QFT-G) blood test, 1119–1121

Quantitative computed tomography (QCT), 242–245

Quinidine, 86–92

R
Rabies virus, 517–519
Radial arterial puncture, 1256, 1259–1260
Radial scar, 1143–1147
Radiation necrosis, 963–966
Radiation therapy
beta-2-microglobulin and, 881
bone marrow biopsy during, 174–177
cancer antigen levels in, 284–285
erthropoietin level and, 581
folate levels and, 627
gastric emptying scan and, 643
human growth hormone and, 683
immunofixation electrophoresis and, 731
immunoglobulin level with, 28, 738
renin value and, 1037
renin and aldosterone assay and, 1058
vitamin D and, 1221
WBC and differential in, 400–403

Radialulopathy, 566–567

Radioactively labeled iodine uptake (RAIU), 1021–1023
Radioactive perfusion scan, 804–807
Radioactive scan
renin value and, 1037
vanillylmandelic acid level and, 1203
vitamin D and, 1221

Radioactive seed, planting, 524–526

Radioactivity

Radionuclide hypersensitivity, 890
Radiograph
of bone, 245–248
of liver, 800–803
of lung, 804–807

RAIU (radioactive iodine uptake), 1021–1023

Radiofrequency ablation (RFA), 1024–1027
Radiographic absorptiometry, 242–245

Radiography
cystoscopy and, 523
skeletal, 1027–1029

Radionuclide scan, 1163
of bone, 245–248
of liver, 800–803
of lung, 804–807

RAP (radioallergosorbent test), 26–28

Raynaud’s syndrome
antinuclear antibody and, 106–108
cold agglutinin titer levels in, 342–343
cryoglobulin detection in, 485–486
lupus anticoagulant antibody and, 811–813
plethysmography for, 950–954, 951–954
ultrasonography for, 1129–1131
RDS. See Respiratory distress syndrome (RDS)
RDW (red blood cell distribution width), 388–391
Receptor assays, in breast cancer, 177, 178
Receptor-positive tumor, 179–181
Rectal electromyography, 568–570
Rectal prolapse, proctosigmoidoscopy for, 986–988
Rectal tumor, 1159–1160
Rectum, 985–988
Red blood cell(s). See also Erythrocyte entries
aplasia of, 930–931, 1043–1044
bilirubin levels in, 164–166
complete blood count and, 363, 383–388
direct antiglobulin testing (DAT) of, 457
in urine specimen, 1195
iron and, 764
life span of, 672
osmotic fragility and, 902–903
surface antigens on, 233
trauma to, hemosiderin and, 692–693
Red blood cell cholinesterase, 1030–1032
Red blood cell count, 384–388
Red blood cell distribution width (RDW), 388–391
Red blood cell inclusions, 364
Red blood cell indices, 363, 388–391
Red blood cell morphology, 363–364, 391–396
Reflux
gastroesophageal. See Gastroesophageal reflux (GER)
vesicoureteral, 527–529
Refraction, 1032–1035
Refractive error, 1032–1035
Refractive surgery, 913
Refractory anemia, 393–396
Regional enteritis, 627–628
Regional hypoventilation, 808–810
Regurgitation
echocardiography for, 551–554
upper GI series for, 1172–1174
Reifenstein's syndrome, 629–631
Reiter's syndrome
human leukocyte antigen and, 721–722
Rejection, organ transplant, 740–742
Relapsing fever, 1081–1083
Renal absorption, 825–828
impaired, 940–942
Renal angiography, 78–82
Renal anomaly/abnormality, 771–772
intravenous pyelography for, 756–758
retrograde ureteropyelography for, 1045–1048
Renal artery aneurysm, 79–82, 442–445
Renal artery embolism, 1039–1042
Renal artery stenosis, 1039–1042
Renal biopsy, 191
Renal calculi
abdominal CT of, 404–407
blood creatinine clearance test and, 477–479
cystoscopy for, 524–526
formation of, 271–272
intravenous pyelography for, 756–758
kidney CT for, 442–445
KUB study for, 771–772
magnesium and, 825
panel for, 271–272
retrograde ureteropyelography for, 1045–1048
sodium levels and, 1068–1071
ultrasonography for, 1145–1147
Renal cancer
calcium values in, 261–263
kidney CT for, 442–445
Renal cell, 1195
Renal cell carcinoma, 442–445
Renal contusion, 1040–1042
Renal cyst, 79–82
intravenous pyelography for, 756–758
kidney CT for, 442–445
ultrasonography for, 1145–1147
Renal damage, 1189–1191
Renal defect, 1136–1139
Renal dialysis
beta2-microglobulin levels in, 880–883
copper levels in, 462–463
vitamin B6 and, 1228
Renal disease, 346–350
amino acid levels in, blood test for, 37–38
amylase levels in, 52–53
beta2-microglobulin levels in, 880–883
bleeding time in, 220
blood creatinine clearance test and, 477–479
blood gas analysis in, 227–232
cyclic antidepressants and, 127–128
erthropoietin level in, 581–582
fibrin degradation product and, 618–619
glucose levels in, 659–662
5-hydroxyindoleacetic acid level in, 725–726
lactate dehydrogenase levels in, 775–776
microalbumin and, 877–879
Renal disease (continued)
  osmolality and, 899–902
polycystic. See Polycystic kidney
disease
RBC count in, 385–388
renal angiography and, 78–82
reticulocyte count for, 1043–1044
retrograde ureteropyelography for,
1045–1048
sodium levels and, 1068–1071
total iron-binding capacity and,
765–766
transferrin level in, 1106–1108
uric acid level in, 1186–1188
urinary calcium levels in, 269–271
urine urea nitrogen level in,
1180–1182
vitamin A and, 1227
Renal dysfunction. See also
Renal failure; Renal insufficiency
magnesium level and, 825–828
MRI and, 856
Renal dysplasia, 1039–1042
Renal failure, 84–86, 254–255. See also
Renal insufficiency
amino acid levels in, blood test for,
37–38
amino acid levels in, urine test for, 40
apolipoprotein A and B, 141–143
blood creatinine clearance test and,
477–479
blood gas analysis in, 227–232
BUN level in, 1178–1180
calcitonin stimulation test for,
257–259
carbon dioxide levels in, 278–279
chloride values in, 307–310, 312–314
C-peptide levels in, 468–469
erethropeoitin level in, 581–582
gastrin stimulation test for, 645–647
glucagon level in, 655–657
glycated hemoglobin A1C and,
673–674
HDLc and LDLC levels in, 326–329
homocysteine level and, 710–711
human growth hormone levels in,
683–684
hyperlipoproteinemia and, 800
lipase levels in, 797–799
magnesium level and, 825–828
myoglobin levels in, 894–895
osteocalcin levels and, 904–905
phosphorus levels in, 940–942
potassium levels and, 975–978,
980–982
prealbumin and, 983–984
prolactin level in, 991–993
radioactive iodine uptake and,
1022–1023
renogram for, 1040–1042
retrograde ureteropyelography and,
1046
total cholesterol level in, 330–333
triglyceride levels and, 1109–1111
uterine fibroid embolization and,
1200
venogram and, 1208
vitamin B12 and, 1218–1219
voiding cystourethrography and, 527
Renal function, 547–550
Renal hematoma
  intravenous pyelography for,
  756–758
KUB study for, 771–772
Renal hypertrophy, 1145–1147
Renal infarction, 1039–1042
Renal infectious disease, 1040–1042.

Right upper quadrant, pain in, 1147–1149
Rigid bronchoscopy, 252
Riley-Day syndrome, 712–714
Rinne test, 1122–1124
RNA (ribonucleic acid), 102–104
Rocky Mountain spotted fever, 380–382
Rotator cuff
arthroscopic evaluation of, 147
MRI of, 848
Rotavirus, 517–519
Rouleaux, 364, 392, 577
Rubella antibody, 1051–1053
Rubella virus, 517–519
Rubeola antibody, 1053–1054
Ruptured viscus, 771–772
RUQ (right upper quadrant), pain in, 1147–1149
S
Salicylate intoxication
blood gas analysis in, 227–232
carbon dioxide levels in, 278–279
chloride values in, 308–310
phosphorus levels in, 940–942
Saline, excessive infusion
chloride values in, 307–310
sodium levels in, 1065–1067
Saliva, 883
*Salmonella*, 506–509
Salmonellosis, 603–604
Salpingitis, 786–788
Salt-losing nephritis, 308–310
Sandhoff’s disease, 705–706
Saponification, 265
Sarcoidosis
alkaline phosphatase levels in, 24–26
angiotensin-converting enzyme in, 83
beta₂-microglobulin levels in, 880–883
blood gas analysis in, 227–232
calcium values in, 261–263
cryoglobulin detection in, 485–486
electromyography for, 566–567
eosinophil count in, 573–575
immunoglobulin E level in, 737–738
liver and spleen scan for, 801–803
liver biopsy for, 194–197
lung biopsy for, 198–201
lung ventilation scan for, 808–810
lymph node biopsy for, 202–205
mediastinoscopy for, 868–871
oxalate levels in, 910–912
parathyroid hormone levels in, 921–922
protein level in, 996–998
pulmonary angiography of, 74–77
pulmonary function study for, 1016–1017
rheumatoid factor and, 1049–1050
urinary calcium levels in, 268–271
vitamin D and, 1220–1222
WBC and differential in, 400–403

Sarcoma
  barium enema and, 157–159
  urinary calcium levels in, 268–271

Sarcosine, 40–41

Scarlet fever
  antistreptolysin O antibody in, 111
  Gram stain for, 680–681
  syphilis serology testing for, 1081–1083

Scheie's classification, 676

Schiller's test, 182–185

Schirmer tear test, 1055–1056

Schistocyte, 363, 392

Schistosoma baematobium infection, 908–909

Schistosoma japonicum infection, 908–909

Schistosoma mansoni infection, 908–909

Schistosomiasis, 908–909

D-xylose tolerance test for, 547–550
  immunoglobulin levels with, 28
  urinary calcium levels in, 269–271

Schizophrenia
  aldolase levels in, 18–19
  FDG-PET scan for, 598–601
  PET scan for, 963–966

Schizotypal personality disorder, 712–714

Schwabach test, 1122–1125

Schwartz syndrome, 676–677

Scintigraphy, 4–7

Scleritis, 1062–1064

Scleroderma, 106–108

D-xylose tolerance test for, 547–550
  esophageal manometry for, 583
  gastric emptying scan for, 643–645
  rheumatoid factor and, 1049–1050
  skin biopsy for, 212–214

Sclerosing cholangitis
  antineutrophilic cytoplasmic antibodies in, 103–104
  ERCP in, 321–324
  percutaneous transhepatic cholangiography in, 315–318

Scoliosis
  chest x-ray for, 302–303
  pulmonary function study for, 1016–1017
  scrotum, 1161–1163

Scurvy
  alkaline phosphatase levels in, 25–26
  folate level in, 627–628
  vitamin C and, 1227, 1228

Seborrhic keratosis, 212–214

Secondary fibrinolysis, 539–541

Secondary glaucoma, 752–755

Secondary polycythemia, 384–388

Sedative, 563

Sedentary lifestyle
  cardiac scoring for, 421–424
  creatine kinase and, 474–475

Seizure disorder, 1228
  EEG determining, 563–564
  PET scan for, 963–966

Semen analysis, 1057–1059

Semenic vesicle tumor, 1159–1160

Sensorimotor neuropathy, 591–594

Sensorineural hearing loss, 1071–1073

Sepsis
  ACTH levels in, 10
  bacterial culture for, 498–501
  ionized calcium values in, 265–267

Septal defect
  coronary angiography of, 70–73
  echocardiography for, 551–554
  lung perfusion scan and, 805
  myocardial perfusion heart scan for, 890–893
  transesophageal echocardiography of, 555–557

Septic shock, 10

Septicemia
  bacterial culture for, 498–501
  cystoscopy and, 524
  WBC and differential in, 400–403

Serial skeletal x-ray, 1027–1029

Serine, 40–41

Serotonin, 724

Serous fluid, 931, 935, 954

Sestamibi scan, 888

Sexually transmitted diseases (STDs), 493–497

SGOT (aspartate aminotransferase), 149–152

SGPT (alanine aminotransferase), 13–15

Shaffer's classification, 676

Shaving biopsy, 212–214

Sheehan's syndrome, 991–993

Shellfish allergy
  hysterosalpingography and, 728
  intravenous pyelography and, 756
  retrograde ureteropyelography and, 1046
  retrograde urethrography and, 1183
  uterine fibroid embolization and, 1200
Shellfish allergy (continued)
venogram and, 1208
vertebroplasty and, 1212
voiding cystourethrography and, 527
Shift to the left, 373, 398, 573–575
Shift to the right, 373
Shigella, 506–509
Shigellosis, 603–604
Shingles, 1206
Shock
alanine aminotransferase levels in, 13–15
amino acid levels in, 37–38
aspartate aminotransferase levels in, 150–152
asthmatic, 277–279
blood creatinine clearance test and, 478–479
blood gas analysis in, 227–232
BUN level in, 1178–1180
catecholamine levels in, 287–290
glucose levels in, 659–662
hematocrit in, 369–372
hypoxic, 474–475
lactate dehydrogenase levels in, 775–776
lactic acid levels and, 777–779
myoglobin levels in, 894–895
plethysmography and, 952
septic, 10
urine creatinine clearance test and, 482–484
Short luteal phase syndrome, 989–990
Shoulder, MRI of, 847
Shunt
blood gas analysis with, 227–232
CT angiography of, 409–412
echocardiography for, 551–554
transesophageal echocardiography of, 555–557
Sickle cell anemia
AcP levels in, 4
bone marrow biopsy for, 174–177
cholinesterase enzyme in, 1030–1032
erthrocyte sedimentation rate and, 577–578
follicle-stimulating hormone level in, 630–631
hemoglobin electrophoresis and, 689–691
hemosiderin levels in, 692–693
LAP levels in, 796–797
MRI for, 848–850
protein levels in, 1004–1006
ultrasonography for, 1164–1166
uric acid level in, 1186–1188, 1189–1191
Sickle cell screen, 1060–1061
Sickling hemoglobin, 1060
Sideroblastic anemia
erythrocyte protoporphyrin levels in, 576–577
folate level in, 627–628
iron level in, 762–764
LAP levels in, 796–797
reticuloocyte count for, 1043–1044
total cholesterol level in, 331–333
total iron-binding capacity and, 765–766
Siderophilin, 1106–1108
Sigmoid torsion, 157–159
Sigmoid volvulus, 157–159
Sildenafil (Viagra), 890
Silent disease, 3/4
Single-energy x-ray absorptiometry
(SXA), 242–245
Single-photon emission computed
tomography (SPECT), 885, 889
Sinopulmonary disease, 737–738
Sinusitis, 734–735
Sjogren’s syndrome
antinuclear antibody and, 106–108
Anti-SS-A/La and, 106–108
cryoglobulin detection in, 485–486
immunoglobulin E level in, 737–738
rheumatoid factor and, 1049–1050
Schirmer tear test for, 1055–1056
Skeletal defect, 1136–1139
Skeletal disorder, chest x-ray and, 301–303
Skeletal fluorosis, 920–922
Skeletal muscle CK-MM, 473–474
Skeletal muscle injury, 894–895
Skeletal x-ray, 1027–1029
Skin
bacterial culture of, 492–497
fungal culture of, 514–516
Skin biopsy, 212–214
Skin disease
albumin/globulin ratio in, 16–18
protein level in, 996–998
vitamin A and, 1227
Skin infection, 566
Skin test, 1118–1122
Skull fracture/contusion, 837–839
SLE. See Systemic lupus erythematosus
(SLE)
Sleep, 815
Sleep apnea, 563–564, 1014
Slit-lamp biomicroscopy, 1061
Small airway disease, 1014
Small bowel
capsule endoscopy of, 273–276
gastric emptying scan of, 642–645
Small bowel ischemia, 547–550
Small bowel resection
5-hydroxyindoleacetic acid level and, 725–726
vitamin B₁₂ and, 1218–1219
Small bowel series, 1171–1174
Small bowel tumor
capsule endoscopy for, 274–276
upper GI series for, 1172–1174
Smear, 487–492
Smoking, 595–597
acquired methemoglobinemia and, 874
apolipoprotein A and, 141–143
cancer gas analysis in, 227–232
carbon dioxide levels in, 280–282
cardiac scoring for, 421–424
catecholamine level and, 1203
FDG-PET scan imaging and, 599
glucose levels and, 780
glucose tolerance test and, 667–669
HDLC level in, 326–329
PET scan and, 964, 967, 971
plethysmography and, 951
pulse oximetry and, 1018
semen analysis and, 1058
ultrasonography and, 1130
vitamin C and, 1229
Sodium. See also Hypernatremia; Hyponatremia
in blood specimen, 1064–1067
in urine specimen, 1068–1071
Sodium depletion, 312–314
Soft tissue, 1077
MRI of, 847–850
Soft-tissue abnormality, 1028–1029
Soft-tissue mass
intravenous pyelography for, 756–758
KUB study for, 771–772
mammography for, 862–864
MRI for, 840–843, 855–857
Somatosensory evoked response (SER), 590
Somatostatinoma, 659–662
Spasm, 583
Specimen
biopsy, 677–679
blood. See Blood specimen
cervical vaginal, semen analysis and, 1059
clean-catch. See Clean-catch specimen; Urine specimen
clotting, 949
expectorated, 532
fluid, 1263
hemolyzed, 949
icteric, 811
lipemic, 811
stool, 1263. See also Feces
timed. See Timed specimen
tissue, 1265
urine. See Clean-catch specimen;
Urine specimen
Specimen quality, 577–578
Spectrophotometry, 15–18
Speech recognition threshold, spondee, 1071–1073
Sperm motility, semen analysis for, 1057–1059
Spermatocoele, 1161–1163
Spermatogenesis, 1084
S-phase fraction (SPF), in breast cancer, 177, 178
Spherocyte, 364, 392
Spherocytosis
bone marrow biopsy for, 174–177
erythocyte sedimentation rate and, 577–578
osmotic fragility and, 902–903
RBC indices in, 389–391
Sphincter electromyography, 520–523
Sphincter muscle, 568–570
Spina bifida, 446–449
Spinal block, 182–185
Spinal cord, 520–523
Spinal cord compression, 446–449
Spinal cord injury, 591–594
Spinal cord ischemia, 409–412
Spinal fracture, 1212
Spinal stenosis
electromyography for, 565–567
MRI for, 848–850
Spinal tumor, 446–449
Spine
computed tomography of, 445–449
vertebroplasty of, 1211–1214
Spine curvature, 1016–1017
Spirometry, 1012–1017
Spleen
computed tomography of, 449–453
iron storage in, 764–765
trauma to, KUB study for, 771–772
ultrasonography of, 1163–1166
Spleen scan, 800–803
Splenectomy
eosinophil count in, 573–575
platelet count in, 379–382
Splenic infiltration, 450–453
Splenic laceration
abdominal CT of, 404–407
splenic CT of, 450–453
Splenic mass, 1164–1166
Splenomegaly
abdominal laparoscopy for, 782–785
hematocrit in, 369–372
Splenomegaly (continued)
- hemoglobin electrophoresis for, 689–691
- hemoglobin in, 374–378
- ultrasonography for, 1164–1166
SpO₂ (arterial blood oxygen saturation), 1018–1020
Spondylothesis
- MRI in, 848
- radiography in, 1028
- spine CT in, 446
Spondylosis
- MRI for, 848–850
- spinal CT for, 446–449
Spontaneous abortion, AFP levels in, 615
Sporothrix schenckii, 515–516
Sprue, 627. See also Celiac disease; Tropical sprue
Sputum
- bacterial culture of, 501–506
- fungal culture of, 514–516
Squamous cell, 1195
Squamous cell carcinoma, 915–916
- calcium values in, 261–263
- skin biopsy for, 212–214
ST segment, 559–561
- ST segment depression, 595–597
Standard gestational tolerance test, 665, 668
- Standard oral tolerance test, 665, 668
- Standard precautions, 1283, 1285–1287
Standing, prolonged periods of, 975–978
Staphylococcal sepsis, 357–358
Staphylococcus, 494–497
- Staphylococcus aureus, 494–497
Starvation. See also Malnutrition
- aldosterone levels in, 20–22
- bilirubin levels in, 164–166
- BUN level in, 1178–1180
- carbon dioxide levels in, 278–279
- glucose levels in, 659–662
- ketone level in, 767–770
- potassium levels and, 980–982
- protein level in, 996–998
- uric acid level in, 1186–1188
Stature
- blood creatinine clearance test and, 478–479
- creatine kinase and, 474–475
STDs (sexually transmitted diseases), 493–497
Steatorrhea, 606
Stein-Leventhal syndrome
- DHEAS and, 542–543
- follicle-stimulating hormone level in, 630–631
- prolactin level in, 991–993
Sterosis
- barium enema for, 157–159
- CT angiography of, 408–412, 409–412
- echocardiography for, 551–554
- ultrasonography for, 1126–1128, 1129–1131
Stent placement, 58, 66
Stereotactic biopsy, 1074–1077
Sterile fluid, 514–516
Sterility
- semen analysis for, 1057–1059
- vitamin A and, 1228
Steroid therapy
- ACTH levels in, 11
- alpha₁-antitrypsin levels in, 138–139
- haptoglobin level in, 686–687
- LAP levels and, 796
- prealbumin and, 983–984
Steroid-induced diabetes, 748–749
Stimulants, 563
Stomach. See also Gastric entries
- capsule endoscopy of, 273–276
- esophagogastroduodenoscopy of, 586–589
- gastric emptying scan of, 642–645
- upper GI series of, 1171
- urea breath test of, 1175–1177
Stomach biopsy, 1175
Stomatocyte, 364, 392
Stool. See Feces
Stool antigen test, 1175
Stool specimen, 1263. See also Feces
Strabismus, 750–752
Strep throat, 680–681
Streptococcal antideoxyribonuclease-B, 122–124
Streptococcal pneumoniae
- bacterial culture for, 494–497
- bacterial pneumonia and, 502
Streptococcus pyogenes, 509–511
Stress
- alpha₁-antitrypsin levels in, 138–139
- antidiuretic hormone and, 129–130
- apolipoprotein B and, 141–143
- cardiac scoring for, 421–424
- catecholamine level and, 1203
- cortisol levels in, 465–467
- eosinophil count in, 573–575
- glucagon level in, 655–657
- glucose level in, 658–662
- glucose tolerance test for, 666–669
human growth hormone levels in, 683–684
LAP levels in, 796–797
LDLC level in, 327–329
luteinizing hormone secretion and, 815–816
RBC count in, 384–388
renin value and, 1037
triglyceride levels and, 1109–1111
urinalysis for, 1193
WBC and differential in, 399–403
zinc level in, 1235–1236
Stress testing
exercise, 594–597
fetal, 1135
vasodilator and, 889
Stress thallium, 888
Stricture
bronchoscopy for, 250–253
capsule endoscopy for, 274–276
cystoscopy for, 524–526
esophagogastrooduodenoscopy for, 586–589
hepatobiliary scan for, 701–704
hysterosalpingography and, 728
percutaneous transhepatic cholangiography for, 315–318
proctosigmoidoscopy and, 986
retrograde ureteropyelography for, 1045–1048
retrograde urethrogram for, 1183–1185
upper GI series for, 1172–1174
Stroke, 295–298
Strongyloides stercoralis infection, 908–909
Strongyloidiasis, 908–909
Subacute bacterial endocarditis, 577–578
Subacute endocarditis
erthrocyte sedimentation rate and, 577–578
RBC count in, 385–388
Subacute sclerosing panencephalitis, 295–298
Subacute thyroiditis, 1022–1023
Subaortic stenosis
echocardiography for, 551–554
transesophageal echocardiography of, 554–557
Subdural empyema, 837–839
Subdural hematoma, 417–420
Subluxation, 147–149
Subphrenic abscess, 1148–1149
ultrasonography for, 1164–1166
Succinylcholine hypersensitivity
acetylcholinesterase and, 1030
pseudoacetylcholinesterase level in, 1012
Sucralfate, 1175
Sulfate, 663
Superficial venous thrombosis, ultrasonography for, 1169
Superior vena cava obstruction, 868
Suppository, 606
Suprapubic aspiration
for bacteria culture, 513
for urinalysis, 1198
for urine cytology, 536
Suprapubic pain, 1139
Surfactant, 792–795
Surgery
D-dimer and, 539
mammography and, 863
plasminogen levels in, 946–947
prolactin level in, 991–993
skeletal muscle CK-MM and, 474–475
WBC and differential in, 400–403
Surgical stress, 1098–1099
Swan-Ganz catheter, 301–303
Sweat chloride, 311–314
Sweating
chloride values in, 310–314
loss of chloride from, 308
magnesium level and, 823–824
potassium levels and, 976–978
sodium levels and, 1065–1067, 1068–1071
vitamin D and, 1220–1221
Symptomatic porphyria, 705–706
Syndrome of inappropriate ADH secretion (SIADH), 129–130
osmotic concentration and, 900–902
Syndrome X
CRP assay for, 471–472
glucose levels in, 659–662
HDLC and LDLC levels in, 326–329
total cholesterol level in, 331–333
triglyceride levels and, 1110–1111
Synovial fluid analysis, 1077–1080
Synovial tumor, arthrogram for, 144
Synovitis
arthrogram of, 144–146
arthroscopy of, 147–149
MRI for, 848–850
Synovium, trapped, arthroscopy for, 147–149
Syphilis
cerebrospinal fluid analysis for, 295–298
erthrocyte sedimentation rate and, 577–578
rheumatoid factor and, 1049–1050
Syphilis serology, 1081–1083
Systemic lupus erythematosus (SLE)
antimitochondrial/antismooth muscle antibody in, 101–102
antinuclear antibody and, 106–108
beta_2-microglobulin levels in, 880–883
Systemic lupus erythematosus (SLE)  
(continued)  
cold agglutinin titer levels in, 342–343  
complement protein levels in, 357–358, 359–360  
copper levels in, 462–463  
CRP assay for, 471–472  
cryoglobulin detection in, 485–486  
direct antiglobulin testing (DAT) for, 457–458  
erthrocyte sedimentation rate and, 577–578  
hyperlipoproteinemia and, 799–800  
immunoglobulin E level in, 737–738  
lar biopsy for, 194–197  
lung biopsy for, 198–201  
lupus anticoagulant antibody and, 811–813  
lymph node biopsy for, 202–205  
pericardial fluid analysis for, 932–934  
platelet antibody and, 948–949  
pleural fluid analysis and, 956–958  
rheumatoid factor and, 1049–1050  
skin biopsy for, 212–214  
synovial fluid analysis and, 1078–1080  
syphilis serology testing for, 1082–1083  
WBC and differential in, 400–403  
Systemic mastocytosis, 639–642  
Systemic neoplasm, 129–130  
T  

T₃ (triiodothyronine), 1112–1113  
free, 1112–1113  
total, 1114–1116  
T₄ (triiodothyronine) toxicosis, 1112–1113  
T₄ (thyroxine), 1093, 1097  
free, 1099–1101  
total, 1101–1104  
T₄-binding albumin, 1097  
T₄-binding globulin, 1097–1099  
T₄-binding globulin deficiency, 1097  
T₄-binding prealbumin, 1097  
T cells (T lymphocytes), 398  
enumeration of, 291–293  
T wave, 559–561  
Tachycardia  
cardiac CK-MB and, 474–475  
electrocardiogram for, 559–561  
exercise stress test for, 595–597  
Taenia saginata infection, 908–909  
Taenia solium infection, 908–909  
Tamponade, 551–554  
Tangier disease  
HDLC and LDLC levels in, 326–329  
total cholesterol level in, 331–333  
Tanner stages, 1084  
Tapeworm disease, 908–909, 1218–1219  
Target cell, 363, 392  
Target heart rate, 594–597  
Tarsal tunnel syndrome, 571–572  
Tattoo, 833, 837, 841, 844, 848, 852, 856, 859  
Tau protein, 32–34  
Taurine, 40–41  
Tay-Sachs disease  
amniotic fluid analysis for, 48–51  
hexosaminidase level in, 705–706  
TBG (thyroxine-binding globulin), 1097–1099  
TBil (total bilirubin), 162–166  
Teardrop cell, 363, 392  
Tearing deficiency, 1055–1056  
Technetium-99 agent, 889  
Technetium-99 pertechnetate, 864–867  
Technetium-99 stannous pyrophosphate (PYP) scanning, 885  
Temperature, environmental, 952  
Temporal arteritis, ESR and, 577–578  
Temporal lobe seizure, 563–564  
Tendon xanthoma  
LDLC level in, 327–329  
Teratogenesis, 1228  
Testicle abnormality, 1161–1163  
Testicular atrophy, 1058–1059  
Testicular biopsy, 109–110  
Testicular cancer, 109–110  
Testicular carcinoma, 614–617  
Testicular dysfunction, 630–631  
Testicular efferent duct, blocked, 109–110  
Testicular failure, 1058–1059  
Testicular infection, 1161–1163  
Testicular inflammation. See Orchitis  
Testicular torsion  
infertility and, 109–110  
ultrasonography for, 1162–1163  
Testicular tumor, 1085–1086  
Testis, 542  
Testosterone, 542, 1084–1086  
Testosterone-producing tumor, 1098–1099  
Tetanus  
aldolase levels in, 18–19  
electromyography for, 566–567  
skeletal muscle CK-MM and, 474–475  
Tg (thyroglobulin), 1087–1088  
TGs (triglycerides), 605, 1108–1111  
Thalassemia  
copper levels in, 462–463  
ferritin level in, 609–610  
hemoglobin electrophoresis for, 689–691
iron level in, 762–764
osmotic fragility and, 902–903
RBC indices in, 390–391
RBC morphology in, 393–396
sickle cell screen for, 1060–1061
total iron-binding capacity and, 765–766
Thalassemia major
  amino acid levels in, urine test for, 40
  hemosiderin levels in, 692–693
  total cholesterol level in, 331–333
Thallium scan, 888
Theca lutein cyst, 989–990
Theophylline administration, 976–978
Thermal stress, 20–22
Thiamine, 1226
Thoracentesis, 16–18
Thoracentesis fluid analysis, 954–958
Thoracic aortic disease, 844–846
Thoracic aortic dissection, 554–557
Thoracic outlet syndrome, 571–572
Thorax. See Chest entries
Threatened abortion
  amniotic fluid analysis in, 46
  chorionic villus biopsy in, 185
  fetal fibronectin in, 611
  human chorionic gonadotropin level in, 715
  progesterone testing in, 989–990
  ultrasound biophysical profile in, 1134–1139
Threonine, 40–41
Throat
culture from, 509–511
  MRI of, 836
Thorboangitis obliterans, plethysmography for, 950–954
Thrombocyte, 378–382
Thrombocythemia, 378, 379–382
Thrombocythemic purpura, 663
Thrombocytopenia, 378
  bleeding time in, 220
  LAP levels in, 796–797
  lupus anticoagulant antibody and, 811
  platelet antibody and, 948–949
  platelet count in, 379–382
Thrombocytopenic purpura
  bone marrow biopsy for, 174–177
  ultrasonography for, 1164–1166
  WBC and differential in, 400–403
Thrombocytosis, 4, 378
Thromboembolism, lupus anticoagulant antibody and, 811
Thrombolytic therapy, 894–895
Thrombopoiesis, 380
Thrombopoietin deficiency, 380–382
Thrombosis
  antithrombin III and, 135
  cardiolipin antibody in, 114
  D-dimer and, 539
  Doppler flow study for, 950
  kidney biopsy in, 191
  lupus anticoagulant antibody and, 811
  MRA for, 829
  MRI for, 833
  plethysmography for, 951
  renogram for, 539
  TEE in, 555
  ultrasonography for, 1169
Thrombotic thrombocytopenic purpura, platelet count in, 380–382
Thrombus
echocardiography for, 551–554
  transesophageal echocardiography of, 554–557
Thymoma, 1
Thyrocalcitonin, 256–259
Thyroglobulin, 1087–1088
Thyroid cancer, 112–113
calcitonin stimulation test for, 257–259
cortisol levels in, 465–467
thyroglobulin values in, 1087–1088
thyroid biopsy for, 215–217
ultrasonography for, 1167–1168
Thyroid disease
  antimitochondrial/antismooth muscle antibody in, 101–102
copper levels in, 462–463
thyroid-binding inhibitory immunoglobulin and, 1089
Thyroid dysfunction
  albumin/globulin ratio, 16–18
  antidiuretic hormone and, 129–130
Thyroid failure, 1114–1116
Thyroid gland. See also Hyperthyroidism; Hypothyroidism
  biopsy of, 215–217
carcinoma of, 112–113. See also Thyroid cancer
cyst of
  biopsy for, 215–217
  ultrasonography for, 1167–1168
disease/dysfunction of. See Thyroid disease; Thyroid dysfunction
radioactive iodine uptake by, 1021–1023
ultrasonography of, 1166–1168
Thyroid hormone, 1087–1088. See also Hyperthyroidism; Hypothyroidism;
  Thyroxine; Triiodothyronine
Thyroid scan, 1089–1092
Thyroid storm, 400–403
Thyroid surgery, 1087–1088
Thyroid toxicity, 566–567
Thyroid-binding immunoglobulin, 1095
Thyroid-binding inhibitory immunoglobulin, 1089
Thyroiditis
  calcitonin stimulation test for, 257–259
  complement protein levels in, 357–358
  radioactive iodine uptake and, 1022–1023
  thyroglobulin values in, 1087–1088
  thyroid scan for, 1090–1092
  thyroid-stimulating hormone and, 1093–1095
Thyroid-stimulating hormone, 1093–1095
Thyroid-stimulating immunoglobulin (TSI), 1096–1097
Thyrotoxicosis
  calcium values in, 261–263
  fecal fat and, 606–608
  glucose levels in, 659–662
  potassium levels and, 976–978
  radioactive iodine uptake and, 1022–1023
  thyroglobulin values in, 1087–1088
  thyroid scan for, 1090–1092
  thyroid-stimulating hormone and, 1093–1095
Thyroxine, 1093, 1097
  free, 1099–1101
  total, 1101–1104
Thyroxine-binding albumin, 1097
Thyroxine-binding globulin (TBG), 1097–1099
Thyroxine-binding globulin deficiency, 1097
Thyroxine-binding prealbumin, 1097
Tidal volume, 1013
Timed specimen
  for D-xylose tolerance test, 547–550
  for magnesium measurement, 826
  for microalbumin testing, 878
  oxalate levels and, 912
  phosphorus levels and, 944–945
  porphyrin levels and, 960–962
  potassium levels and, 981
Tine test, 1118
Tinnitus, 154–156
Tissue, 1027–1029
Tissue necrosis
  ceruloplasmin levels in, 299–300
  fibrinogen level in, 620–622
  prealbumin and, 983–984
  WBC and differential in, 400–403
Tissue poisoning, 400–403
Tissue sample, 1263
Tissue trauma
  magnesium level and, 822–824
  potassium levels and, 975–978
Tobacco. See Smoking
Tobramycin, 92–96
Tocopherol, 1222
Toddler communication, 1265–1266
Togavirus, 517–519
Tomography. See Computed tomography (CT); Positron emission tomography (PET)
Tonsillitis, 680–681
TORCH panel, 537, 1104
Torsion, 1162–1163
Total bilirubin (TBil), 162–166
Total cholesterol, 329–333
Total lung capacity, 1013
Total parenteral nutrition
  ammonia levels with, 44–45
  hepatobiliary scan and, 702
Total thyroxine, 1101–1104
Total triiodothyronine, 1114–1116
Total iron-binding capacity, 764–766
Total protein C levels and, 811
Toxemia
  aldosterone levels in, 20–22
  erythrocyte sedimentation rate and, 577–578
  fibrinogen level and, 621
  lactic acid levels and, 777
  lupus anticoagulant antibody and, 811
Toxic chemicals, 400–403
  WBC and differential in, 400–403
Toxic hepatitis, 24–26
Toxoplasma antibody, 1104
Toxoplasma gondii, 1104
Toxoplasmosis, 1104
Tracheal suctioning, 532–533
Tracheostomy tube, chest x-ray and, 301–303
Trachoma, 1062–1064
Transbronchial lung biopsy, 197
Transcatheter bronchial brushing, 198
Transcutaneous bilirubin monitor, 163
Transducer, 554
Transesophageal echocardiography (TEE), 554–557
Transferrin, 764, 1106–1108
Transfusion
  bilirubin levels in, 164–166
  bone marrow biopsy after, 175–177
  calcium and, 261–263
  cytomegalovirus and, 537
  direct antiglobulin testing (DAT) for, 457–458
  erythropoietin level and, 581
  fibrinogen level and, 621
  haptoglobin level in, 686–687
  hemoglobin in, 686–687
  hemoglobin levels after, 690
  hemosiderin levels in, 692–693
  hepatitis B antigen/antibodies and, 722–724
  iron level and, 761, 762–764
  platelet antibody and, 948–949
  platelet count in, 380–382
  potassium levels and, 975–978
  rheumatoid factor and, 1049–1050
  transfusion reaction
    acute immune-mediated, 1269–1270
    acute non-immune-mediated, 1270–1271
    delayed immune-mediated, 1272
    delayed non-immune-mediated, 1272
  Transitional cell, 1195
  Transmission, of microorganism, 1277–1279
  Transmission-based precautions, 1283–1285
  Transthyretin, 982
  Transudate, 931, 935, 954
  Transverse position (of fetus), 1136–1139
  Trauma
    abdominal angiography of, 58–61
    abdominal CT of, 404–407
    albumin/globulin ratio, 16–18
    amylase levels in, 52–53
    brain CT of, 417–420
    carotid angiography of, 67–69
    cerebrospinal fluid analysis for, 295–298
    chloride values in, 307–310
    complement protein levels in, 359–360
    copper levels in, 462–463
    coronary angiography of, 70–73
    electromyography in, 566–567
    electroneurography for, 571–572
    glucagon level in, 655–657
    glucose levels in, 659–662
    gonioscopy for, 676–677
    hearing loss audiometry for, 154–156
    ionized calcium values in, 265–267
    liver and spleen scan for, 801–803
    mammography for, 862–864
    otoscopy for, 906–907
    peritoneal fluid analysis for, 936–938
    platelet count in, 380–382
    plethysmography for, 950–954
    potassium levels and, 975–978
    renogram for, 1040–1042
    skeletal muscle CK-MM and, 474–475
    splenic CT of, 450–453
    synovial fluid analysis and, 1078–1080
    to RBC, hemosiderin and, 692–693
    ultrasonography for, 1148–1149, 1164–1166
    voiding cystourethrography for, 527–529
  Traumatic nerve transection, 570
  Trematode disease, 908–909
  Treponema, 816
  Treponema pallidum, 494–497, 1081
  Trichinosis, 18–19
  Trichomonas vaginalis, 915, 917
  Trichophyton, 515–516
  Trichuriasis, 908–909
  Tricyclic antidepressants, 133–134, 544–547
  Tricyclic glycopeptide, 92–96
  Trigeminal neuralgia, 119
  Triglycerides (TGs), 605, 1108–1111
  Triiodothyronine, 1112–1113
    free, 1112–1113
    total, 1114–1116
  Triiodothyronine toxicosis, 1112–1113
  Triple X syndrome, 334
  Triple-marker testing, 613, 614, 715
  Trophoblastic tumor, 1085–1086
  Tropical sprue, 261–263
    copper levels in, 462–463
    D-xylose tolerance test for, 547–550
    fecal fat and, 606–608
    glucose tolerance test for, 666–669
    5-hydroxyindoleacetic acid level in, 724–726
    intestinal biopsy for, 188–190
    urinary calcium levels in, 269–271
  Troponins I and T, cardiac, 1116–1118
  Trypanosomiasis
    cold agglutinin titer levels in, 342–343
    syphilis serology testing for, 1081–1083
Trypsin, 602–603
Tryptophan, 40–41
Tsanck smear, 212–214
Tuberculous meningitis, 295–298
Tuberculin skin test, 1118–1122
Tuberculosis
alkaline phosphatase levels in, 24–26
blood gas analysis in, 227–232
bronchoscopy for, 250–253
calcium values in, 260–263
carbon dioxide levels in, 278–279
chest x-ray for, 302–303
copper levels in, 462–463
culture and smear, 487
eosinophil count in, 573–575
erthrocyte sedimentation rate and, 577–578
lung biopsy for, 198–201
lung perfusion scan for, 805–807
lung ventilation scan for, 808–810
mediastinoscopy for, 868–871
*Mycobacterium kansasii*, 488
platelet count in, 380–382
pleural fluid analysis and, 956–958
erosinophi test for, 1118–1122
vitamin A and, 1228
zinc level in, 1235–1236
Tuberculosis meningitis, 129–130
Tuberculous arthritis, 1078–1080
Tuberculous empyema, 956–958
Tuberculous pericarditis, 932
Tuberos xanthoma, 327–329
Tubular carcinoma, 1143–1147
Tubular necrosis
MRI for, 833–835
renogram for, 1040–1042
Tubular phase, 1039–1042
Tumor(s). See also particular types and site-specific entries
abdominal angiography of, 58–61
abdominal CT of, 404–407
albumin/globulin ratio and, 16–18
barium enema for, 157–159
barium swallow for, 160–162
bilirubin levels in, 164–166
bladder biopsy for, 166–169
blood gas analysis in, 227–232
bone marrow biopsy for, 174–177
bone scan for, 245–248
brain CT of, 417–420
breast biopsy for, 179–181
bronchoscopy for, 250–253
BUN level in, 1178–1180
calcitonin stimulation test for, 257–259
cancer antigen levels in, 284–285
capsule endoscopy for, 274–276
carbon dioxide levels in, 277–279
carotid angiography of, 67–69
cerebrospinal fluid analysis for, 295–298
chest x-ray for, 302–303
colonoscopy for, 347–350
colonoscopy for recurrence of, 426–429
copper levels in, 462–463
coronary angiography of, 70–73
C-peptide levels in, 468–469
CT angiography of, 408–412
cystoscopy for, 524–526
DHEAs and, 542–543
echocardiography for, 551–554
EEG determining, 563–564
ERCP for, 321–324
erosinopeitin level in, 581–582
esophagogastroduodenoscopy for, 586–589
estradiol level in, 589–590
evoked brain potentials in, 591–594
fecal analysis for, 605–604
fluorescein angiography for, 623–625
folic acid level in, 627–630
hearing loss audiometry for, 154–156
hepaticobiliary scan for, 701–704
human chorionic gonadotropin level in, 715–717
human growth hormone levels in, 683–684
5–hydroxyindoleacetic acid level in, 724–726
hysterosalpingography for, 728–730
intravenous pyelography for, 756–758
kidney CT for, 442–445
liver and spleen scan for, 801–803
liver biopsy for, 194–197
liver/biliary tract CT of, 412–414
lung ventilation scan for, 808–810
lymphangiography for, 819–821
mammography for, 862–864
metanephrine levels and, 872–873
myocardial infarction scan and, 886

Davis's Comprehensive Laboratory and Diagnostic Handbook—*with Nursing Implications*
INDEX
Ultrasonography (continued)
of lymph nodes and retroperitoneum, 1150–1152
of pancreas, 1152–1154
of pelvis (gynecologic/nonobstetric), 1155–1158
of prostate, 1158–1160
of scrotum, 1161–1163
of spleen, 1163–1166
of thyroid and parathyroid glands, 1166–1168
stereotactic biopsy and, 1074
venous Doppler, extremity studies with, 1168–1170
Ultrasound biophysical profile, 1134–1139
Ultrasound densitometry, 242–245
Umbilical cord sampling, 1256
Unconjugated/indirect bilirubin, 162–166
Underventilated alveoli, 30–32
Upper duodenum
capsule endoscopy of, 273–276
esophagogastroduodenoscopy of, 586–589
Upper gastrointestinal series, 1171–1174
Upper gastrointestinal tract, 586
Upper respiratory tract infection, 518–519
Urate, 1185–1188
Urea, 1004
Urea breath test, 1175–1177
Urea nitrogen
in blood specimen, 1177–1180
in urine specimen, 1180–1182
Uremia, 84–86
abdominal laparoscopy and, 783
glucose levels and, 660
platelet count in, 380–382
potassium levels and, 975–978
pseudocholinesterase level in, 1012
testosterone and, 1085–1086
vitamin B₆ and, 1228
WBC and differential in, 400–403
Ureter, 755–758
Ureteral calculi, 756–758
Ureteral obstruction
kidney CT for, 442–445
ultrasonography for, 1145–1147
Ureteral orifice, 523–526
Ureteral stent, 524–526
Ureteral stricture
cystoscopy for, 524–526
voiding cystourethrography for, 527–529
Ureterocele
ultrasonography for, 1140–1141
voiding cystourethrography for, 527–529
Ureteropelvic junction obstruction, 1045–1048
Urethra
cystoscopy of, 523–526
voiding cystourethrography of, 526–529
Urethral calculi, 1183–1185
Urethral diverticula
retrograde urethrogram for, 1183–1185
voiding cystourethrography for, 527–529
Urethral fistula, 1183–1185
Urethral obstruction, cystometry and, 521
Urethral stricture, 524–526
Urethritis
Chlamydia antibody testing for, 304–306
cystoscopy and, 524
Urethrography, retrograde, 1183–1185
Urethroscopy, 523
Uric acid, 242–245
in blood specimen, 1185–1188
in blood versus urine, 1189
in urine specimen, 1188–1191, 1196
Urinalysis, 1192–1199
Urinary bladder. See Bladder
Urinary calcium, 267–271
Urinary catheterization
for bacteria culture, 513
for urinalysis, 1198
for urine cytology, 536
Urinary elimination dysfunction
cystometry and, 520–523
cystoscopy and, 523–526
Urinary tract
urine cytology for
cancer, 535
inflammatory disease, 535
Urinary tract abnormality
cystoscopy for, 524–526
intravenous pyelography for, 756–758
retrograde ureteropyelography for, 1045–1048
Urinary tract infection (UTI)
bacterial culture for, 512–514
cystometry for, 520–523
microalbumin and, 877–879
protein levels in, 1004–1006
renogram for, 1040–1042
urine cytology for, 534–536
voiding cystourethrography and, 526–527
Urinary tract malignancy, 1004–1006
Urinary tract obstruction
BUN level in, 1178–1180
ultrasonography for, 1140–1141
urine creatinine clearance test and, 482–484

Urine
albumin levels in, 876–879
amino acid screening, 39–41
bacterial culture for, 511–514
beta2–microglobulin levels in, 881–883
bladder cancer markers in, 218–219
catecholamine levels in, 286–290
cellular elements of, 1195
color of, 1193
creatinine levels in, 480–484
crystals in, 1196
cytology of, 534–536
dipstick analysis of, 1192, 1196
immunofixation electrophoresis of, 731–733
ketones, measuring levels in, 769
magnesium level in, 822–824
microscopic analysis of, 1192
osmotic concentration in, 899–902
oxalate levels in, 910–912
protein level in, 1003–1006
urea nitrogen in, 1180–1182
uric acid level in, 1188–1191
urinalysis of, 1192–1199
vitamin D and, 1220–1221

Urine phosphate, 942

Urine specimen. See also Clean-catch specimen
collection procedure for, 1261–1263
for drug abuse, 545
patient preparation for, 1261

Urinary tract infection (UTI)

Uterus
gynecologic laparoscopy of, 785–788
hysterosalpingography of, 727

Vaccinia
syphilis serology testing for, 1082–1083

Vacuum-assisted needle biopsy, 1074
Vacuumized needle and holder system, 1258–1259

Vagal hyperfunction, 640–642
Vaginal adenosis, 917
Vaginitis, 1195
Vagotomy
gastrin stimulation test for, 645–647
glucose tolerance test for, 666–669

Valine, 40–41
Valproic acid, 117–121

Valsalva technique, 1169

Valve competency, 951–954
Valvular calcification, 886
Valvular disease, 70–73
Vancomycin, 92–96
Vancomycin-resistant enterococci (VRE), 512–514

Vanillylmandelic acid (VMA), 712

Varicella, 212–214
Varicella antibody, 1205–1207
Varicella-zoster antibody, 1205–1207
Varicella-zoster virus, 517–519

Varicocele
infertility and, 109–110
semen analysis for, 1058–1059
ultrasonography for, 1162–1163

Varicose vein, 1169–1170

Vascular abnormality
colonoscopy for, 347–350
MRA for, 829–831
proctosigmoidoscopy for, 986–988

Vascular blockage, 67–69

Vascular calcification, 862–864

Vascular disease
MRI for, 855–857
renogram for, 1040–1042

Vascular disorder
chest x-ray for, 302–303
CT angiography of, 408–412
fluorescein angiography for, 623–625
hearing loss audiometry for, 154–156

Vascular injury
fibrinogen level and, 621
Vascular injury (continued)
lupus anticoagulant antibody and, 811
protein C levels and, 999, 1002
Vascular lesion, 441–445
Vascular malformation, 446–449
Vascular phase, 1039–1042
Vascular system, 966–970
Vascular trauma, 951–954
Vasculitic disease, 103–104
Vasculitis
antineutrophilic cytoplasmic antibodies in, 103–104
beta2–microglobulin levels in, 881–883
complement protein levels in, 359–360
WBC and differential in, 400–403
Vasectomy, 1057–1059
Vasectomy reversal
infertility and, 109–110
semen analysis for, 1057–1059
Vasoconstriction, 1019
Vasoconstrictor, angiotensin II as, 1035–1039
Vasodilator-mediated myocardial perfusion scan, 889
Vector borne transmission of pathogen, 1278
Vegetable deficiency
potassium levels and, 976–978
vitamin B12 and, 1218–1219
Vegetarian diet, 482–484
Vein(s), lower extremity
Doppler study of, 1168–1170
venogram of, 1207–1211
Venogram, 1207
Venography, lower extremity study, 1207–1211
Venous blood gas, 1215–1217
Venous plethysmography, 950–954
Venous sonogram, 1168–1171
Venous thrombosis
antithrombin III levels in, 135
cardiopulmonary complex in, 114
D-dimer and, 539
Doppler flow study for, 950
kidney biopsy in, 191
MRI for, 833
renogram for, 1040
ultrasonography for, 1169
Venous trauma, 1170
Venous ultrasound, 1168–1170
Ventilation-perfusion scan, 804–807
Ventricular aneurysm, 551–554
Ventricular displacement, 417–420
Ventricular dysfunction, 254–255
Ventricular hypertrophy
echocardiography for, 551–554
electrocardiogram for, 559–561
exercise stress test and, 595–597
transesophageal echocardiography of, 555–557
Ventricular mural thrombus
echocardiography for, 551–554
transesophageal echocardiography of, 554–557
Ventricular septal defect
lung perfusion scan and, 805
myocardial perfusion heart scan for, 890–899
Ventricular thrombus, echocardiography for, 551–554
Ventriculitis, 837–839
Vertebroplasty, 1211–1214
Very-low-density lipoprotein (VLDL), 799–800
Very-low-density lipoprotein cholesterol (VLDLC), 326
Vesicoureteral reflux, 527–529
Vessel occlusion
  MRA for, 829–831
  ultrasonography for, 1129–1131
Vessel stenosis, 829–831
Viagra (Sildenafil), 890
Viral culture, 517–519
Viral hepatitis
  alkaline phosphatase levels in, 24–26
  amino acid levels in, urine test for, 40
  antimitochondrial/antismooth muscle antibody in, 101–102
  complement protein levels in, 357–358
  fecal fat and, 606–608
  G6PD levels in, 663
  lactate dehydrogenase levels in, 775–776
  syphilis serology testing for, 1082–1083
Viral infection
  beta2–microglobulin levels in, 881–883
  bone marrow biopsy for, 174–177
  complement protein levels in, 357–358
  fecal analysis for, 603–604
  platelet count in, 380–382
  skin biopsy for, 212–214
  sputum cytology for, 530–534
  WBC and differential in, 400–403
Viral load, 291
Viral pericarditis, 932–934
Virilization, 542–543
Virilizing ovarian tumor, 1085–1086
Virtual colonoscopy, 425
Virus, 400–403
Visceral injury, 801–803
Visceral larva migrans, 28
Viscus, ruptured, 771–772
Visual acuity, 1032–1035
  Visual acuity scale, 1033
  Visual cortex defect, 591–594
  Visual evoked response (VER), 590
  Visual field test, 1215–1217
Visual loss
  MRI for, 858–861
  nerve fiber analysis for, 896–898
  visual field test for, 1215–1217
Vital capacity, 1013
Vitamin(s)
  aPTT and, 927
  BUN level and, 1178
  oxalate levels and, 911
  parathyroid hormone and, 921–922
  phosphorus levels and, 943
  Vitamin A, 1226–1230
  Vitamin B1, 1226–1230
  Vitamin B6, 1226–1230
  Vitamin B12, 1217–1219
  Vitamin B12 deficiency
    bone marrow biopsy for, 174–177
    folate level in, 626–628
    glucose levels and, 659–662
    homocysteine level and, 709–711
    iron level and, 762–764
    RBC morphology in, 393–396
    WBC and differential in, 399–403
  Vitamin C, 1226–1230
    deficiency and alkaline phosphatase levels, 25–26
    fecal analysis and, 603
    sources of, 1230
  Vitamin D, 1220
    calcium values and, 260, 261
    ionized, 265–267
    urinary, 269–271
    phosphorus levels and, 940–942, 943–945
  Vitamin deficiency, 1228
    amino acid levels in, urine test for, 40
    RBC indices in, 389–391
    toxicity and, 1223
  Vitamin E, 1222–1224
  Vitamin K
    disease affecting, 1225–1226
    forms of, 1224
    osteocalcin and, 903
  Vitamin K deficiency
    antithrombin III levels in, 135–136
    aPTT in, 927–929
    prothrombin time and, 1008–1011
  Vitamin K-dependent protein, 999, 1001, 1007
  Vitreous traction syndrome, 1216–1217
  VLDL (very-low-density lipoprotein), 799–800
  VLDLC (very-low-density lipoprotein cholesterol), 326
  VMA (vanillylmandelic acid), 712
    urine, 1203–1205
  Voiding, bladder pressure during, 521
  Voiding cystography, 526–529
  Voiding cystourethrography, 526–529
  Voiding disorder, 520–523
  Voluntary ventilation, 1012–1017
  Volvulus, 157–159
    colonoscopy and, 347
    proctosigmoidoscopy and, 985
  Vomiting, 84–86
    acetaminophen intoxication and, 55
    antihypertensive toxicity and, 89
    anticonvulsant toxicity and, 120
    antipsychotic toxicity and, 133
    blood gas analysis in, 227–232
    carbon dioxide levels in, 277–279
    chloride values from, 308–310
Vomiting (continued)
digoxin toxicity and, 89
D-xylose level and, 547–550
EM and, 583
GER and, 648
GER scan and, 648
glucose tolerance test and, 667–669
illness with, ketones and, 767–770
magnesium and, 823
MRI for, 858–861
phosphorus levels in, 940–942
potassium levels and, 976–978, 980–982
radioactive iodine uptake and, 1022
salicylate toxicity and, 55
sodium levels and, 1065–1067
thyroid scan and, 1090
urine porphyrins and, 960
von Gierke disease
  glucose levels in, 659–662
  glucose tolerance test for, 666–669
total cholesterol level in, 330–333
von Willebrand’s disease
  aPTT in, 927–929
  bleeding time in, 220
V/Q scan, 804–807, 807–810
VRE (vancomycin-resistant enterococci), 512–514
Waldenstrom’s macroglobulinemia
  albumin/globulin ratio, 16–18
cryoglobulin detection in, 485–486
erthrocyte sedimentation rate and, 577–578
  immunofixation electrophoresis for, 731
  immunoglobulin E level in, 737–738
  protein level in, 996–998
  rheumatoid factor and, 1049–1050
total cholesterol level in, 331–333
WBC and differential in, 400–403
Wall motion study, 237–241
Warfarin, 539
Warkam syndrome, 334
Wärn, 212–214
Wash-in phase, 808
Wash-out phase, 808
Wasting disease
  aldolase levels in, 18–19
  BUN level in, 1178–1180
  creatinine clearance and, 482
Water intoxication
  chloride values in, 308–310
  osmotic concentration and, 900–902
Waxy cast, 1196
WBC. See White blood cell entries
Weber test, 1123–1124
Wegener’s granulomatosis, 102–104
Wegener’s syndrome, 102–104
Weight loss
  apolipoprotein A and B in, 141–143
  upper GI series for, 1172–1174
Welding industry, lead and, 789–791
Werner’s syndrome
  apolipoprotein B and, 141–143
total cholesterol level in, 331–333
  triglyceride levels and, 1110–1111
Whipple’s disease
  alkaline phosphatase levels in, 25–26
  D-xylose tolerance test for, 547–550
  fecal fat and, 606–608
  folate level in, 627–628
  glucose tolerance test for, 666–669
  5–hydroxyindoleacetic acid level in, 725–726
White blood cell count/differential,
  396–403
  complete blood count and, 362, 365–367
  glucose levels and, 660
White blood cell scan, 1231–1233
Whole blood
  bleeding time, 220
  blood gas analysis, 221–223
Whole body bone scan, 245–248
Wilson’s disease
  amino acid levels in, urine test for, 40
  blood gas analysis in, 227–232
  ceruloplasmin levels in, 299–300
copper levels in, 462–463
  liver biopsy for, 195–197
  uric acid level in, 1187–1188,
  1189–1191
  urinary calcium levels in, 268–271
  zinc level in, 1234–1236
Wiskott-Aldrich syndrome
  immunoglobulin E level in, 734–735,
  737–738
  platelet count in, 380–382
Wolf-Parkinson-White syndrome,
  595–597
Wolf-Hirschhorn syndrome, 334
Woman
  follicle-stimulating hormone level in, 628
  prolactin level in, 990
testosterone in, 1084–1086
Workplace screening, 544–547
Worm parasite, 733
Wound culture
  for bacteria, 492–497
  white blood cell scan for, 1231–1233
Wrist
  MRI of, 847
venipuncture of, 1255
x-ray of, 1027–1029

X
Xenon gas, 807–810
Xenon lung scan, 807–810
X-ray
  chest, 301–303
  skeletal, 1027–1029
  upper GI series and, 1172
D-Xylose tolerance test, 547–550
XYY Klinefelter’s syndrome, 334

Y
Yersinia enterocolitica, 506–509

Z
Zenker’s diverticulum, 587
Zidovudine (AZT), 881–883
Zinc, 1234–1236
Zinc deficiency, 1234
  alkaline phosphatase levels in, 25–26
  vitamin A and, 1228
Zollinger-Ellison syndrome
  alkaline phosphatase levels in, 25–26
  calcitonin stimulation test for, 257–259
  D-xylose tolerance test for, 547–550
  fecal fat and, 606–608
  gastric acid stimulation test and, 640–642
  gastric emptying scan for, 642–645
  gastrin stimulation test for, 645–647
  parathyroid hormone levels in, 921–922
Zymogens, 338
